**Abstract**

**Background:** Vestibular schwannoma (acoustic neuroma) most commonly presents with ipsilateral disturbances of acoustic, vestibular, trigeminal and facial nerves [5]. Contralateral trigeminal nerve dysfunction as a false localizing sign in acoustic neuroma has been documented [3,6,7]. Contralateral facial pain presenting as trigeminal neuralgia has been mentioned as false localizing sign for posterior fossa and cerebellopontine angle tumors [1,10,4,2]. However presentation of the vestibular schwannoma with contralateral facial pain is quite uncommon. Among 156 patients with vestibular schwannoma who underwent surgery at Sina hospital during past 6 years, we encountered one case with this unusual presentation.

**Case presentation:** Among 156 cases of operated vestibular schwannoma, we found one case with unusual presentation of contralateral hemifacial pain.

**Conclusion:** The presentation of contralateral facial pain in the vestibular schwannoma is rare. It seems that displacement and distortion of the brainstem and compression of the contralateral trigeminal nerve in Meckel's cave by the large mass lesion may lead to this atypical presentation. The best practice in these patients is removal of the tumour, although persistent contralateral pain after operation has been reported.
schwannoma. Postoperatively (Fig. 2) her right hemifacial pain was relieved and her corneal reflexes returned to normal activity. The left facial nerve function could not be preserved.

Discussion
Contralateral facial pain associated with cerebellopontine angle and posterior fossa tumors has been attributed to different reasons such as the tumor size and displacement of the brainstem, angulations and distortion of the nerve roots, anatomic variation of posterior fossa, the relationships of cranial nerves and nearby blood vessels and the compression of the contralateral trigeminal nerve in Meckel’s cave by the tumor [2,6]. In this report we present a vestibular schwannoma with constant contralateral trigeminal pain. The very early report by Snow and Frazer [10] on a vestibular schwannoma described tic doloreux. Samii and Matthies reported the increased incidence of vascular compression pain in ipsilateral tumors, namely vestibular schwannomas [8]. Sepehrnia and Schulte reported a case of contralateral neuralgia caused by a meningioma [9]. The constant presence of the pain is not typical of a vascular compression syndrome. We did not identify any vascular abnormality around the trigeminal nerve in high-resolution MR images. The main cause of pain in our case seems to be displacement and distortion of the brainstem and less probably compression of the contralateral trigeminal nerve in Meckel’s cave by the tumor.

In some patients, removing of the tumor results in relief of contralateral pain. This seems to be due to return of the brainstem to its normal position and reversing the contralateral pain producing mechanism, as has happened with our case. Persistent contralateral pain after removal of the contralateral posterior cranial fossa tumor has been attributed to arachnoid adhesions and arterial loops [2].

Conclusion
Contralateral facial pain is a rare presentation of the giant vestibular schwannomas. The causative mechanism is most probably displacement and distortion of the brainstem and less probably compression of the contralateral trigeminal nerve in Meckel’s cave by the large mass lesion. The best practice in these patients is removal of the tumour, although persistent contralateral pain after operation has been reported.

Acknowledgement
We thank Dr. Mehdi Nassiri Fellow in Hematopathology, University of Miami, Florida for his comments and help. Written consent was obtained from the patient for publication of the patient’s details.

Figure 2
Postoperatively, the tumour is totally removed and place of the craniectomy is seen. The brainstem seems to be returned to rather normal position.
