Abstract: Insulin is implicated as a leading factor in glucose homeostasis and an important theme in diabetes mellitus (DM). Numerous proteins are involved in insulin signaling pathway and their dysregulation contributes to DM. microRNAs (miRNAs) as single-strand molecules have a critical effect on gene expression at post-transcriptional levels. Intensive investigation done by DM researchers disclosed that miRNAs have a significant role in insulin secretion by direct targeting numerous proteins engaged in insulin signaling pathway; so, their dysregulation contributes to DM. In this review, we presented some major miRNAs engaged in the insulin production and secretion.

Keywords: insulin, diabetes mellitus, microRNAs, insulin signaling pathway

Introduction
Insulin, as an endocrine hormone, serves as a mediator in glucose metabolism and energy storage. This spherical miniprotein hormone (5.8 kDa) is derived from the intermolecular disulfide bridge (CysA7-CysB7 and CysA20-CysB19) between peptide chains of the A-chain (Ins-A, 21 amino acid residues) that contains an intramolecular disulfide bridge (CysA6-CysA11) and B-chain (Ins-B, 30 amino acid residues). Pancreatic islets in mammals are rich in beta-cells and are assumed as the only source of circulating insulin. Freshly synthesized insulin in beta-cells is initially produced as the prohormone proinsulin. Later, it is converted into mature insulin by the prohormone convertase action (PC1, PC2, encoded by Pcsk1 and Pcsk2, respectively) during shuttling by the secretory pathway. Active insulin is kept in condensed core secretory granules (5–10,000 per cell), while each of these granules contains 300,000 or more molecules of insulin. According to the literature, changes in insulin secretion are one of the main reasons for the beginning of diabetes mellitus (DM). In the current research, we introduced the major pathways involved in insulin granule fusion, focused on most important miRNAs that contributed to insulin production and secretion, and finally discussed miRNA-therapy as a novel approach to alleviate diseases such as DM.

Proteins Involved in Docking and Fusion
High-affinity interaction between SNAREs, as highly conserved proteins, which are soluble N-ethylmaleimide-sensitive factor attachment protein receptor, has a significant effect on insulin granule docking, priming, and fusion. These proteins include synaptobrevin-2 (VAMP), stx-1, and SNAP-25 (25-kDa synaptosomal-associated protein): Stx-
1 and SNAP25 are plasma membrane proteins and are named t-SNAREs (target SNAREs); VAMP exists in the vesicle or granule membrane and is often called v-SNAREs (vesicle SNAREs), in this protein as a homologous SNARE motif is composed of 60–70 amino acids. The four SNARE motifs (stx-1 has one SNARE motif, VAMP has a separate SNARE motif, while SNAP 25 has two SNARE motives) combine together to establish a ternary complex that has a significant effect on insulin granules' fusion with the plasma membrane.5

The cAMP Role in Insulin Granule Exocytosis
The regulator activity of cAMP in various cellular functions of various cell types has changed cAMP into an important universal intracellular messenger.6 The cAMP generation from ATP is catalyzed by adenylyl cyclases (ACs) and 10 members of this enzyme family have been identified while their expressions in islet cell were proved.7 In insulin secretion, it has been long known that cAMP action is mediated by protein kinase A (PKA)8 of proteins associated with the secretory process through phosphorylation.

ATP-Sensitive Potassium Channel
The ATP-sensitive potassium channel (KATP channel) is a metabolic sensor, which is able to couple a cell’s metabolic status with electrical activity and adjusts various cellular functions. In pancreatic beta-cells, KATP channels regulate the secretion of insulin.9 With regard to structure, KATP channels, as large hetero-octameric complexes include four regulatory sulphonyleurea receptors (SURx) and four pore-forming (Kir6.x) (via cytoplasmic domains bind to ATP) subunits, which are encoded by ABCC8 and KCNJ11, respectively.10,11 Considering the KATP channel activity, the membrane is held at a hyperpolarized level that results in voltage-gated Ca2+ channels’ closure.12 A rise in the serum glucose triggers the pancreatic beta-cell to uptake glucose through glucose transporter GLUT2. Later, glucose converts into ATP via subsequent mechanisms.10 By binding to Kir6.2, ATP closes the KATP channel; this closure can be facilitated by Epcac2, which binds with the channel’s SUR1 subunit.13,14 As a result, a membrane depolarization is created that opens channels of the voltage-gated Ca2+ and initiates the beta-cell electrical activity as well as Ca2+ influx. Subsequently, increase in [Ca2+] stimulates the insulin release.12

G Protein-Coupled Receptor (GPCR)
G protein-coupled receptors (GPCR), as versatile, seven-transmembrane-domain proteins, are responsible for regulating various intracellular signaling arrays cascade in response to hormones, neurotransmitters, and ions.15 In this regard, G proteins include heterotrimer proteins consisting of the α, β, and γ subunits. Although G proteins differ basically in amino acid with regard to their sequence of the α-subunit, such as Gs, Gi, and Gq, many of them can couple with the GPCRs. Gs makes the adenylate cyclase active and increases production of cAMP and activates protein kinase A (PKA) and the Epac (exchange proteins that are activated by cAMP directly) family of cAMP-regulated guanine nucleotide exchange factors. Both PKA and Epac contain multiple downstream effectors in insulin secretion. Gi is responsible for inhibiting the adenylate cyclase and stimulating the mitogen-activated protein kinase (MAPK). In order to produce inositol 1,4,5-triphosphate (IP3) and diacylglycerol (DAG), Gq stimulates PLC-β. Finally, IP3 stimulates the Ca2+ release from the endoplasmic reticulum, while DAG makes protein kinase C active.16

MicroRNAs are introduced as a class of gene expression negative regulators involved in developing endocrine pancreas and regulating insulin secretion.17

Biogenesis and Maturation of miRNA
The miRNA genes, transcribed by RNA polymerase II (Pol II), are controlled by RNA Pol II-associated transcription factors and epigenetic regulators. In this regard, long primary transcript (pri-miRNA) that span over 1kb has a local hairpin structure, which contains miRNA sequences.18 The nuclear RNase III Drosha and DGC8 create a complex: Microprocessor. This Microprocessor copies the stem–loop and initiates the maturation process in order to release a small hairpin-shaped RNA of ~65 nucleotides in length (pre-miRNA).19 After this export, pre-miRNA is cleaved next to the terminal loop by Dicer and liberates a small RNA duplex consisting of a passenger and guide strand.20 Subsequently, this RNA duplex forms the effector complex of RNA-induced silencing complex (RISC) after loading onto an AGO protein.21 Following the above-mentioned process, the pre-RISC (in which AGO proteins are associated with RNA duplexes) eliminates the passenger strand quickly and generates a mature RISC that performs gene silencing (Figure 1).22 Following miRNA duplex loading, the pre-RISC (in which AGO proteins associate with RNA duplexes) quickly removes the passenger strand to generate
a mature RISC that performs gene silencing. In this review, we tried to introduce better miRNAs involved in insulin secretion and production (Table 1, Figure 2).

**miR-7**

MiR-7, as an intronic miRNA, is mapped to the initial intron of heterogeneous ribonuclear protein K gene on chromosome 9. MiR-7 has been evolutionarily conserved and has recently emerged as a prototypical neuroendocrine miRNA. Among the neurons and neuroendocrine organs most significantly enriched in miR-7 the endocrine pancreas, pituitary, and adrenal glands can be mentioned.

The mTOR, as a serine/threonine kinase, acts as a growth regulator as well as nutrient sensor. It exists as part of two functionally and biochemically distinct complexes: mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2). The mTORC2 was found to mediate the phosphorylation of Akt/PKB at ser47. Phosphorylation Akt at ser 473 activates Akt for further phosphorylation in catalytic domain at Thr 308. Akt and 3-phosphoinositide–dependent protein kinase-1 (PKD1) trigger full activation of Akt, which is very important for glucose uptake. Furthermore, it was found that miR-7 down-regulated Akt, mTOR, and P70S6K transcription, which are considered as the major components of PI3K/Akt pathway.

**miR-9**

MiR-9 is produced by mapping three genes of miR-9-1, miR-9-2, and miR-9-3 in the human genome to chromosomes 1, 5,
MiR-9 mediate insulin exocytosis in insulin-producing cells through direct targeting Onecut-2 (OC-2) mRNA. As a result, decreased expression of the OC-2 can increase the Granuphilin levels, as its target gene. Additionally, it is well known that Granuphilin acts as a negative regulator of insulin secretion.

The sirtuins family of proteins are NAD-dependent protein deacetylases involved in numerous physiological processes, such as apoptosis, cell growth, stress response, and energy metabolism. This family has been found to have seven members involving Sirt 1-7. Mammalian Sirt1 is widely expressed in mammalian tissues and functions as a nuclear protein. As its main characteristic, mammalian Sirt1 can deacetylate histones’ co-regulators in a NAD-dependent manner and transcription factors. As a member of the mitochondrial inner membrane proteins, UCP2 has been implicated to promote proton leakage across the mitochondrial. In this way, UCP2 through decreasing ATP synthesis reduces insulin secretion. It is also of great importance that Sirt1 binds to the UCP2 promoter and abolishes UCP2 transcriptional activation. In this manner, Sirt1 regulates insulin secretion. Furthermore, recent investigations have introduced mir-9 as a key factor in modulating Sirt1 expression in the living organism. As Saunders et al reported, mir-9 targets Sirt1 in embryonic stem cells of rats. However, the intensive investigation conducted by Ramachandran et al showed that the above-mentioned process (mir-9 targeting of Sirt1) is a significant physiological process in insulin-secreting cells.

**miR-29**

The miR-29 family includes four mature members including miR-29a, miR-29b1, miR-29b2, and miR-29c. These members are encoded by two gene clusters of miR-29b2/miR-29c (mapped on chromosome 1q32) and miR-29b1/miR-29a (mapped on chromosome 7q32). Heterodimer-type (Class I) PI3Ks consists of a regulatory subunit that is at least encoded by three distinct genes (85α, p85β, p55γ) and a p110 catalytic subunit. The p85α is the most frequently expressed regulatory isoform of PI3K, which encodes two minor alternative splicing isoforms of p55α and p55β additionally. It also binds to tyrosine-phosphorylated proteins, like Insulin Receptor Substrate-1 (IRS-1), and activates PI3K activity of the pll0 subunit in insulin signaling. The miR-29 targets p85α directly and affects insulin signaling. Furthermore, miR-29 develops gluconeogenesis by aiming at hepatic p85α and enhancing expression of the phosphoenolpyruvate carboxykinase (PEPCK).

As we mentioned previously, syntaxin-1a (Stx-1a) is an important factor in insulin granule fusion with the plasma membrane. An experimental study conducted by Bagge...
et al \(^47\) over INS-1E cells disclosed that miR-29a targeted the Stx-1a transcript directly and decreased Stx-1a mRNA and protein levels.

**miR-34a**

Among the mammals, the family of miR-34 includes three processed miRNAs that reside in two various genes of miR-34a and miR-34b/c, which are located on 1p36 and 11q23, respectively.\(^48\) The researchers found that miR-34a affects the hepatic insulin signaling by targeting Sirtuin 1 (SIRT1).\(^49\)

**miR-124a**

MiR-124a family, which is mainly expressed in the brain and pancreas, includes three processed miRNAs, which are encoded by three various genes of miR-124a1, miR-124a2, and miR-124a3, which are located on chromosome 14, chromosome 3, and chromosome 2, respectively.\(^50,51\) Forkhead box A2 (FOXA2)/Hepatocyte Nuclear Factor 3 \(\beta\) (HNF3\(\beta\)) is a member of the forkhead box family and belongs to the liver transcription factors including FOXA1 and FOXA3 (or HNF3\(\alpha\), HNF3\(\gamma\)).\(^52\) We should also consider these factors’ conserved DNA binding domain and binding (as monomers) to the DNA elements that are homologous with the consensus sequence 5’- T(G/A)TTT(A/G)(C/T)T-3’.\(^53,54\) Different levels of FOXA2 expression (high and low) are observed in the liver and other tissues, respectively.\(^55\) FOXA2, as a transcriptional activator of Pdx-1, Sur1, preproinsulin, and Kir6.2 has been implicated in pancreatic beta-cell. So, FOXA2 protein overproduction triggers the up-regulation of Kir6.2, Pdx-1, Sur-1, and preproinsulin mRNA expression.\(^51,56\) Recent investigations demonstrated that miR-124a2 had a crucial effect on insulin secretion by targeting at Foxa2 gene, which regulates insulin secretion.\(^17\)

**miR-143**

The miR-143 has a highly conserved sequence belongs to the miR-143/145 family. It was also found that miR-143 was mapped to chromosome 5.\(^57\) The oxysterol-binding protein (OSBP) as well as OSBP-related proteins (ORPs) form a large family of genes that include sterol/lipid transportations and regulatory activities.\(^58\) ORP8 is located on the endoplasmic reticulum (ER) by its C-terminal transmembrane span and is bound to 25-hydroxycholesterol, which has changed it into a new ER oxysterol-binding protein. According to the literature, ORP8 was most highly expressed in the liver, macrophages, spleen, kidney, and brain and functioned in insulin signaling.\(^59\) Moreover, PIP2 concentration was considered as a phospholipase C (PLC) substrate that hydrolyzes PIP2 to PIP3 and is modulated by ORP8. As a result of binding IP3 to IP3R in the ER, Ca2+ releases to the cytosol.\(^60\) A recent study showed that miR-143 plays an important role in insulin secretion by targeting oxysterol-binding-protein-related protein 8 (ORP8).\(^61\)

**miR-153**

Two copies of miR-153 have been known: A) miR-153-1, which is mapped to a highly conserved region in the intron 19 of IA-2 on chromosome 2 and B) miR-153-2, which resides in a highly conserved intronic region between exon 19 and 20 of IA-2\(\beta\) on chromosome 7. As previously, SNAP-25 and VAMP-2 are required for insulin granule fusion. Recent investigations disclosed that miR-153 played a crucial role in insulin secretion by targeting SNAP-25 and VAMP-2 directly.\(^62\)

**miR-187**

Homeodomain–interacting protein kinases (HIPK1, HIPK2, HIPK3) can interact with the homeobox transcription factors Nkx-1.2.\(^63\) HIPK3 acts as a novel positive regulator of pdx-1 abundance through phosphorylation of pdx-1 (positive regulator of insulin biosynthesis).\(^64\) It is also a direct target of miR-187 with down-regulated expression levels in pancreatic islets of patients with type 2 diabetes.\(^65\)

**miR-204**

MiR-204, as a highly beta-cell-enriched microRNA, is localized within large intron 6 of TRPM3 and mapped to chromosome 9q21.12.\(^66\) Glucagon-like peptide 1 receptor (GLP1R), as a GPCR, is composed of seven transmembrane domains.\(^67\) Increased dosage of GLP1R was reported in pancreatic beta-cells. It also has an important effect on the GLP-1, as the main incretin created in intestinal L-cells and pancreatic islet alpha cells.\(^68,69\) Food-stimulated GLP-1 secretion and its binding to the GLP1R triggers glucose-induced beta-cell insulin secretion via elevation of cAMP concentration.\(^70\) Jo et al discovered that the 3’UTR of GLP1R was a direct target for miR-204 in the beta-cell-derived rat INS-1 cell line as well as the primary mouse and human islets; thereby, the expression was down-regulated. In this manner, miR-204 acts as a negative regulator in insulin secretion.\(^70\)

**miR-375**

Structural organization of MiR-375 gene on human chromosome 2 shows an intergenic spacer between CRYBA2 and...
Pdx-1 is a homeodomain protein with a critical role in pancreatic β-cell function and development. Furthermore, insulin transcription activation resulted from Pdx-1, which is bound to the conserved AT-rich A3 box (−201/−196 bp). However, this protein acts as a repressor in other gene contexts. At low glucose concentrations (1–2mM) in β cells, the nuclear periphery is the main location of Pdx-1. Following the insulin secretion stimulation, Pdx-1 shuttles into the nucleus as a consequence of its phosphorylation. Atypical protein kinase C isoforms, p38/ stress-activated protein kinase, glycogen synthase kinase 3 (GSK3), phosphatidylinositol 3-kinase (PI3K), Per-Amt-Sim (PAS) kinase, and mitogen-activated protein kinase (MAPK) are among the main signaling pathways that adjust shuttling of the nucleo-cytoplasmic and adjust the Pdx-1 transactivation potential. Furthermore, it was disclosed that the Pdx-1 interaction with different transcriptional coregulators was mediated by glucose. Additionally, it was approved that expression of insulin gene under low and non-insulin stimulating glucose concentrations decreased by association of Pdx-1 with the histone deacetylases HDAC-1 and HDAC-2. Furthermore, Pdx-1 SUMOylation regulates its localization and stability. It is also associated with increased activity of insulin promoter. In addition, SUMOylation of Pdx-1 increases its nuclear localization as well as its protein stability and is correlated with an increase in insulin promoter activity. Finally, Pdx-1 is composed of at least two sites of O-GlcNAcylation, which promote its DNA activity of binding. A research indicated that miR-375 regulated insulin secretion by targeting Pdx-1.

Myotrophin with ankyrin repeats mediates the protein–protein interactions in other proteins. Myotrophin functions to remodel F-actin filaments and secretory granules exocytosis. Furthermore, the literature found that miR-375 targets myotrophin mRNA. NeuroD1/Beta2 is a basic helix-loop-helix (bHLH) transcription factor that binds with the ubiquitously expressed E-box proteins at the conserved insulin E1 (−100/−91bp) site in a complex. O-GlcNAcylation of NeuroD1 as a crucial factor for its translocation to the nucleus is mediated by high glucose levels. It was disclosed that miR-375 targets NeuroD1 mRNA.

Conclusion

Insulin secretion plays an important role in preventing hyper- and hypo-glycemic states and its defect develops diabetes mellitus. The miRNAs, which have a significant impact on various disease processes, emerged as important players of gene regulation. Deregulated expression of miRNA has been widely implicated in the insulin-secreting pancreatic beta-cell of patients with type-2 diabetes. As a result, impaired insulin secretion is a major factor in disease progression. So, a more in-depth understanding of the interplay between miRNAs and protein involved in insulin production and secretion may afford valuable insights and novel therapeutic strategies to treat diabetes.

The International Journal of General Medicine is an international, peer-reviewed open-access journal that focuses on general and internal medicine, pathogenesis, epidemiology, diagnosis, monitoring and treatment protocols. The journal is characterized by the rapid reporting of reviews, original research and clinical studies across all disease areas. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
