Abstract

Determining accurately when regime and structural changes occur in various time-series data is critical in many social and natural sciences. We develop and show further the equivalence of two consistent estimation techniques in locating the change point under the framework of a generalised version of the Ornstein-Uhlenbeck process. Our methods are based on the least sum of squared error and the maximum log-likelihood approaches. The case where both the existence and the location of the change point are unknown is investigated and an informational methodology is employed to address these issues. Numerical illustrations are presented to assess the methods performance.

Keywords: Sequential analysis, least sum of squared errors, maximum likelihood, consistent estimator, existence of change point

1. Introduction

1.1. Background

The Ornstein-Uhlenbeck (OU) process is commonly used to model the stochastic dynamics of various financial variables. Certain economic indicators also have stylised properties that are adequately captured by the OU process. Vasicek’s pioneering work (1977), employing an OU model to price a zero-coupon bond, inspired a multitude of research investigations from extensions addressing the model’s weakness of constant mean-reverting level to various applications in economic and financial practice. The importance of this stochastic process is also demonstrated by its ubiquity in many fields. Amongst the finance and finance-related areas highlighting the usefulness of OU process are electricity market (e.g., Erlwein, et al. (2010)), commodity futures market (e.g., Date, et al. (2010)), weather derivatives (e.g., Elias, et al. (2014)), central-bank setting rate policy (e.g., Elliott and Wilson (2007)), stochastic control-driven insurance problems (e.g., Liang, et al. (2011)), spot freight rates in the shipping industry (e.g., Benth, et al. (2015)), risk management (e.g., Date and Bustreo (2015), and power generation (e.g., Howell, et al. (2011)). Applications of the OU process could be as well found in biology (see Rohlfs, et al. (2010)), neurology (see Shinomoto, et al. (1999)), survival analysis (see Aalen and Gjessing (2004)), physics (see Lanský and Sacerdote (2001)), and chemistry (see Lu (2003) and (2004)).

To rectify the classical OU model’s inability to capture the evolution of a process whose mean level varies with time, Dehling, et al. (2010) introduced a generalised OU process in which a time-dependent function describes its mean-reverting level. Such a generalised version incorporates time-inhomogeneity and seasonality of mean reversion simultaneously. Moreover, the generalised OU process is capable of modelling drastic changes in certain time points (e.g., interest rates undergoing drastic moves due to financial crisis, war, etc). Dehling, et al. (2014) developed the framework in the study of a change-point phenomenon in the generalised OU process to model the drastic change.

Our contributions in this paper hinged on the research results primarily from two research articles detailed as follows. The first is the paper of Dehling, et al. (2010) in which a maximum likelihood estimator (MLE) for the drift parameters of the diffusion process is derived and the asymptotic properties, such as the asymptotic distribution of the proposed MLE, are studied. Dehling, et al. (2014) considered an extended model, where there is one unknown change point and constructed a likelihood-ratio test statistic in determining a candidate change point. This line of enquiry was continued by Zhang (2015) who examined the asymptotic properties of both the unrestricted and restricted MLE for the drift parameters of the generalised OU process with a single change point. In particular, based on the established asymptotic distribution of the MLEs, a James-Stein-type shrinkage estimator for the drift parameters is proposed in Zhang (2015) as an improvement. In the estimation of the unknown

change point, Zhang (2015) showed that the previously established asymptotic properties also hold for any consistent estimator for the rate of change point.

Nonetheless, both Dehling, et al. (2014) and Zhang (2015) did not provide any explicit method to estimate the change point. This deficiency inspired the three main contributions of our paper. Firstly, we present two consistent methods to estimate the unknown change point. Secondly, we consider the case where the existence of the change point is uncertain and propose an informational approach to address this existence issue. Thirdly, the performance of the proposed methods is theoretically analysed and validated by a numerical implementation. In practice, many data series are characterised by some potential changes in structure, i.e., a sudden change in mean or variance and other model parameters. It is then of interest to determine the (i) existence and (ii) location of the change point. This implies segregating the data series into different segments and analysing them in a more efficient way.

Investigations concerning change point problems are not new. Inaugural contributions to this field were spearheaded, for example, by Page (1954) and Shiryaev (1963). Recent developments have focused on (i) the estimation of change points and coefficients of linear regression models with multiple change points (cf. Bai and Perron (1998); Perron and Qu (2006); Lu and Lund (2007), Gombay (2010), Chen and Nkurunziza (2015)); (ii) change-point testing for the drift parameters of a periodic mean-reverting process (cf. Dehling, et al. (2014)); (iii) applications in finance (cf. Spokoiny (2009)); (iv) detection of malware within software (Yan, et al. (2008)); and (v) climatology (Reeves, et al. (2007), Robbins, et al. (2011), Gallagher et al. (2012)). In general, the analysis of change points could be described as a hypothesis-testing problem for the existence of change points in various locations. Alternatively, this could be viewed as a model selection problem that treats the change points as the additional unknown parameters to be estimated. However, unlike ordinary least squares estimation, there is so far no closed-form estimation methods to calculate the change point directly or in a few steps. The existing change-point estimation approaches are predominantly designed to perform a search at every possible location of a change point with some efficient computational algorithms until some criteria are satisfied. The well-known algorithms for change point detection are the (i) binary segmentation algorithm (Scott and Knott, (1974); Sen and Shrivastava, (1975)), (ii) segment-neighbourhood algorithm (Auger and Lawrence (1989); Bai and Perron (1998)) with adaption to the restricted regression model (Perron and Qu (2006)), and (iii) PELT algorithm (Killick, et al. (2012)).

There are two types of scenarios for which change-point problems are examined in the literature. In the first scenario, the number of change points is known but their exact locations are unknown (see Perron and Qu (2006) and Chen and Nkurunziza (2015)). The second scenario covers the more general situation in which both the number and the exact locations of the change points are unknown. The estimation methods under the first scenario only require the identification of the exact locations of the change points. Clearly, the performance assessment in the former scenario is relatively easier than that in the latter scenario.

1.2. Motivating examples

1.2.1. West Texas Intermediate (WTI) Cushing crude oil spot prices

The first motivating example of this paper is the West Texas Intermediate (WTI) Cushing crude oil spot prices, which is often being considered as a benchmark in oil pricing. The data set was compiled by Bloomberg with code “USCRWTIC” and covers approximately 4 years of daily prices from 09 November 2011 to 09 November 2015 (i.e., 1008 trading days). During this period (see Figure 7), there is a price decline after September 2014 due to the conflict in the Middle East. It could be recalled that in September 2014, there was an increase in the OPEC oil production led by a rebound in the Libyan output. The dollar, on the other hand, continued to get stronger. These events caused the decline of the crude oil prices and suggested the potential existence of a change point in the data series.

Due to the potential existence of the change point, for this data set the classical OU process without change-point is inappropriate. Our findings show, as detailed in section 6, that applying the classical method to the original data set produces very large Schwarz information criterion (SIC) as compared to the proposed method which takes into account the change point. Indeed, the proposed method increases the log-likelihood value from 0.72 to 11.89 and reduces the SIC by 69%.

1.2.2. XAU currency

The second motivating example of this paper is the XAU currency, which is the standard ticker symbol for one troy ounce of gold, considered as a currency to US dollar. This implementation is carried out to show the nuances in dealing with data sets or its transformed version whose change point is not clear-cut at the outset. The data set is also obtained from Bloomberg with code “XAU”, and it is a 15-year data series ranging from 03 November 2000 to 04 November 2015 (i.e., 3913 trading days).
In particular, we assume that there is one unknown change point \( \omega \), where

\[ \tau \in [0,T]. \]

We start with Zhang’s framework (2015), which assumes that a consistent estimator exists for the existence of the change point. The asymptotics of the estimators are also discussed and hence, the asymptotic properties established in Zhang (2015) also hold in our proposed techniques. The case where the existence and the location of the change point are both unknown is explored in Section 5. We develop an informational approach to detect the change point, and the consistency of our methods is likewise theoretically demonstrated. Section 6 provides the numerical implementation of our proposed methods on both simulated and observed financial market data. The final section gives some concluding remarks.

2. Description of the single-change point problem

Our main consideration in this paper is the change-point estimation strategy under a generalised Ornstein-Uhlenbeck process with only one change point. We start with Zhang’s framework (2015), which assumes that a consistent estimator exists for the unknown change point \( \tau \in [0,T] \). The model under examination is the generalised version of the Ornstein-Uhlenbeck (OU) process with SDE representation

\[ dX_t = S(\theta, t, X_t) dt + \sigma dW_t, \quad 0 < t \leq T, \tag{2.1} \]

where \( S(\theta, t, X_t) = L(t) - aX_t = \sum_{i=1}^{p} \mu_i \varphi_i(t) - aX_t, i = 1, ..., p, \theta = \theta^{(1)} = (\mu_1, ..., \mu_p, -a)^{\prime} \), \( ^{\prime} \) denotes the transpose of a matrix. Also, \( W_t \) is a one-dimensional Brownian motion defined on some probability space \( (\Omega, F, P) \).

In particular, we assume that there is one unknown change point \( \tau = sT, 0 < s < 1 \) such that

\[ S(\theta, t, X_t) = \sum_{i=1}^{p} \mu_i^{(1)} \varphi_i(t) - a^{(1)}X_t, \quad 0 < t < \tau, \]

\[ S(\theta, t, X_t) = \sum_{i=1}^{p} \mu_i^{(2)} \varphi_i(t) - a^{(2)}X_t, \quad \tau \leq t \leq T, \]

where \( \theta = \theta^{(1)} = (\mu_1^{(1)}, ..., \mu_p^{(1)}, -a^{(1)})^{\prime}, \) for \( 0 < t < \tau, \) and \( \theta = \theta^{(2)} = (\mu_1^{(2)}, ..., \mu_p^{(2)}, a^{(2)})^{\prime}, \) for \( \tau \leq t \leq T. \)

For the case when there is no change point, maximum likelihood estimators for the drift parameters and their related asymptotic properties were derived in Dehling, et al. (2010). These results are reviewed in the next section and serve as a springboard for our theoretical discussion.

3. Earlier MLE-based results and our new results

This section consists of two subsections: (i) review of the results for the MLE of the drift parameters (without change point) along with the related asymptotic properties demonstrated in Dehling, et al. (2010); and (ii) review of the MLE for the drift parameters (with one change point) and the related asymptotic properties studied in Zhang (2015).

In Zhang (2015), however, asymptotic normality for the MLE estimator of the drift parameters is derived under the assumption that the estimator is already consistent. In our case, we shall show (instead of assume) that such an estimator of the change point are both unknown is explored in Section 5. We develop an informational approach to detect the change point, and the consistency of our methods is likewise theoretically demonstrated. Section 6 provides the numerical implementation of our proposed methods on both simulated and observed financial market data. The final section gives some concluding remarks.
Therefore, the MLE of the drift parameters is given by

\[ \hat{\theta} = Q^{-1}(0, T) R_{(0, T)}, \]

where

\[ Q_{(0, T)} = \begin{pmatrix} \int_0^T \varphi_1(t) dt & \cdots & \int_0^T \varphi_p(t) \varphi_p(t) dt \\ -\int_0^T \varphi_1(t) dt & \cdots & -\int_0^T \varphi_p(t) \varphi_p(t) dt \\ \int_0^T X^1 \varphi_1 dt & \cdots & \int_0^T X^p \varphi_p dt \end{pmatrix}, \]

and

\[ R_{(0, T)} = \left( \int_0^T \varphi_1(t) dX_t, \ldots, \int_0^T \varphi_p(t) dX_t, -\int_0^T X^1 dX_t \right). \]

Note that the MLE introduced above could be evaluated by applying the Euler’s discretisation to (2.1), and then getting a linear model and applying the ordinary least-squares estimation method to provide an estimator containing the Riemann and Ito sums. Then, the OLS estimator will converge into the MLE estimator as \( \Delta t \to 0 \).

For the existence of \( Q_{(0, T)}^{-1} \), it is shown in Remark 3 of Dehling, et al. (2010) that \( T Q_{(0, T)}^{-1} \) exists almost surely if \( T \) is large enough. Moreover, Proposition 2.1.1 of Zhang (2015) states the positive definiteness of \( \frac{1}{T} Q_{(0, T)} \) under the following assumption.

**Assumption 2.** For any \( T > 0 \), the base function \( \{\varphi_i(t), i = 1, \ldots, p\} \) is Riemann-integrable on \([0, T]\) and satisfies

1. **Periodicity.** That is, \( \varphi_i(t + v) = \varphi_i(t) \), for all \( i = 1, \ldots, p \) and \( v \) is the period observed in the data.
2. **Orthogonality.** That is, for all \( j, k = 1, \ldots, p \), \( \int_0^T \varphi_j(t) \varphi_k(t) dt = 0 \) unless \( j = k \).

**Proposition 3.1** (Proposition 2.1.1 of Zhang, 2015). Under Assumption 2, for any \( T > 0 \) and \( t \in [0, T] \), the base functions \( \{\varphi_i(t), i = 1, \ldots, p\} \) are incomplete if and only if \( \frac{1}{T} Q_{(0, T)} \) is a positive definite matrix.

Hence, for the rest of this paper, we assume that the sample size \( T \) is an integral multiple of the period length \( v \), i.e., \( T = Nv \) for some integer \( N \). Without loss of generality, we let \( v = 1 \) and this implies that \( \varphi_j(t + 1) = \varphi_j(t) \).

Inspired by the results of Dehling, et al. (2010) and Dehling, et al. (2014), Zhang (2015) first studied the case where the
change point in (2.1) exists and known to be $\tau^0 = s^0 T$, $0 < s^0 < 1$ and derived the results in estimating $\theta^{(1)}$ and $\theta^{(2)}$. In particular,

$$\hat{\theta}^{(1)} = Q^{-1}_{(0, \sigma^2 T)} \tilde{R}_{(0, \sigma^2 T)} = \theta^{(1)} + \left( \frac{1}{T} Q_{(0, \sigma^2 T)}^{-1} \right)^{-1} \frac{1}{T} R_{(0, \sigma^2 T)}$$

and

$$\hat{\theta}^{(2)} = Q^{-1}_{(\sigma^2 T, T)} \tilde{R}_{(\sigma^2 T, T)} = \theta^{(2)} + \left( \frac{1}{T} Q_{(\sigma^2 T, T)}^{-1} \right)^{-1} \frac{1}{T} R_{(\sigma^2 T, T)},$$

where $R_{(a,b)} = \left( \int_a^b \varphi_i(t) dW_t, \ldots, \int_a^b \varphi_p(t) dW_t, - \int_a^b X_t dW_t \right)$ for $0 \leq a < b \leq T$.

Also, the asymptotic properties of the above proposed MLEs are well-studied in Dehling, et al. (2010) for the case when there is no change point and Zhang (2015) for the case of a single change point. To summarise these results, we first go back to the case when there is no change point. By (2.1), we have

$$\int_0^T \varphi_i(t) dX_t = \sum_{j=1}^p \mu_j \int_0^T \varphi_i(t) \varphi_j(t) dt - a \int_0^T \varphi_i(t) X_t dt + \sigma \int_0^T \varphi_i(t) dW_t,$$

for $i = 1, \ldots, p$, and

$$\int_0^T X_t dX_t = \sum_{j=1}^p \mu_j \int_0^T X_t \varphi_j(t) dt - a \int_0^T X_t^2 dt + \sigma \int_0^T X_t dW_t.$$

It follows that

$$\hat{\theta} = Q^{-1}_{(0,T)} \tilde{R}_{(0,T)} = \theta + \sigma Q^{-1}_{(0,T)} R_{(0,T)} = \theta + \sigma T Q^{-1}_{(0,T)} \frac{1}{T} R_{(0,T)}.$$

By Ito’s lemma, the SDE in (2.1) has the solution

$$X_t = e^{-at} X_0 + h(t) + N_t,$$

where $h(t) = e^{-at} \sum_{j=1}^p \mu_j \int_0^t e^{at} \varphi_j(s) ds$ and $N_t = \sigma e^{-at} \int_0^t e^{as} dW_s$.

The uniform boundedness of solution (3.5) was studied in Zhang (2015). Using similar methods employed for the proof of Proposition 2.2.1 in Zhang (2015) together with the mean-reversion property in the drift term of the OU process, one may verify that the SDE (2.1) admits a strong and unique solution that is uniformly bounded in $L^2$, and

$$\sup_{t \geq 0} E(X_t^2) \leq K_1,$$

for $0 < K_1 < \infty$.

Note that the process $\{X_t, t \geq 0\}$ is not stationary in the ordinary sense. Thus, it is impossible to apply the ergodic theorem directly. To go around this problem, Dehling, et al. (2010) introduced a stationary solution for $t \in \mathbb{R}$ instead of $t \geq 0$. That is,

$$\bar{X}_t = \tilde{h}(t) + \tilde{N}_t,$$

where $\tilde{h}(t) = e^{-at} \sum_{i=1}^p \mu_i \int_{-\infty}^t e^{as} \varphi_i(s) ds$ and $\tilde{N}_t = \sigma e^{-at} \int_{-\infty}^t e^{as} d\tilde{B}_s$, with $(\tilde{B}_s)_{s \in \mathbb{R}}$ denotes a bilateral Brownian motion, i.e.,

$$\bar{B}_t = B_t 1_{\mathbb{R}_+}(s) + \tilde{B}_t 1_{\mathbb{R}_-}(s).$$

Here, $(B_t)_{t \geq 0}$ and $(\tilde{B}_s)_{t \geq 0}$ are two independent standard Brownian motions and $1_A$ stands for the indicator function over the set $A$. It follows from (3.6) and Lemma 4.3 in Dehling, et al. (2010) that the sequence of $C[0,1]$-valued random variables $W_k(s) = \bar{X}_{k-1+s}$, $0 \leq s \leq 1$, $k \in \mathbb{N}$ is stationary and ergodic. Then, by Proposition 4.5 of Dehling, et al. (2010),

$$\frac{1}{T} \int_0^T \bar{X}_t \varphi_i(t) dt \xrightarrow{a.s.} \int_{-\infty}^1 \tilde{h}(t) \varphi_i(t) dt$$

and

$$\frac{1}{T} \int_0^T \bar{X}_t^2 dt \xrightarrow{a.s.} \int_{-\infty}^1 \tilde{h}^2(t) dt + \frac{\sigma^2}{2a}.$$
Moreover, it follows from Lemma 4.4 in Dehling, et al. (2010) that under Assumption 2,

\[ |X_r - X_d| \xrightarrow{T \to \infty} 0. \tag{3.10} \]

Using (3.10), the following properties hold:

\[
\frac{1}{T} \int_0^T \dot{X}_t \varphi_j(t) dt - \frac{1}{T} \int_0^T X_t \varphi_j(t) dt \xrightarrow{T \to \infty} 0,
\]

and

\[
\frac{1}{T} \int_0^T X_t^2 dt - \frac{1}{T} \int_0^T \dot{X}_t^2 dt \xrightarrow{T \to \infty} 0.
\]

Then it follows from (3.8) and (3.9) that

\[
\frac{1}{T} \int_0^T X_t \varphi_j(t) dt \xrightarrow{T \to \infty} \int_0^1 \tilde{h}(t) \varphi_j(t) dt
\]

and

\[
\frac{1}{T} \int_0^T X_t^2 dt \xrightarrow{T \to \infty} \int_0^1 \tilde{h}^2(t) dt + \frac{\sigma^2}{2a}.
\]

Hence,

\[
T Q_{(0,T)}^{-1} \xrightarrow{T \to \infty} \Sigma_0^{-1},
\tag{3.11}
\]

where

\[
\Sigma_0 = \begin{bmatrix} I_p & \Lambda' \\ \Lambda & w \end{bmatrix},
\]

with \( \Lambda_{(0,T)} = (\int_0^T \tilde{h}(t) \varphi_1(t) dt, \ldots, \int_0^T \tilde{h}(t) \varphi_p(t) dt)' \) and \( w = \int_0^1 \tilde{h}^2(t) dt + \frac{\sigma^2}{2a} \).

Furthermore, under Assumptions 1–2, the following properties hold for \( R_{(0, T)} \):

1. \( \{R_{(0, T)}, T > 0\} \) is a martingale.
2. \( \frac{1}{T} R_{(0, T)} \xrightarrow{T \to \infty} 0 \).
3. \( \frac{1}{\sqrt{T}} R_{(0, T)} \xrightarrow{T \to \infty} R \sim N_{p+1}(0, \Sigma_0) \).

For detailed proofs of the above properties 1-3, see Theorem A.4.3., Propositions 2.1.4 and 2.1.6 in Zhang (2015), respectively.

Based on the above properties, it follows from the Slutsky’s Theorem that

\[
\frac{1}{\sqrt{T}} (\hat{\theta} - \theta) \xrightarrow{T \to \infty} \rho \sim N_{p+1}(0, \Sigma_0^{-1}).
\]

In Chapter 2 and pertinent proofs in Appendix B of Zhang (2015), the above asymptotic properties are extended to the case of a single change point in the following way.

Write

\[
\hat{h}^{(1)}(t) := e^{-a s} \sum_{i=1}^p \hat{\mu}_i^{(1)} \int_s^\infty e^{a s} \varphi_i(s) ds
\]

and

\[
\hat{h}^{(2)}(t) := e^{-a s} \sum_{i=1}^p \hat{\mu}_i^{(2)} \int_s^\infty e^{a s} \varphi_i(s) ds.
\]

Then

\[
\frac{1}{T} \int_0^T \dot{X}_t \varphi_j(t) dt \xrightarrow{T \to \infty} s^0 \int_0^1 (\hat{h}^{(1)}(t) \varphi_j(t) dt)
\tag{3.12}
\]

and

\[
\frac{1}{T} \int_0^T X_t^2 dt \xrightarrow{T \to \infty} s^0 \left( \int_0^1 (\hat{h}^{(1)}(t)^2 dt + \frac{\sigma^2}{2a^{(1)}} \right).
\tag{3.13}
\]
where $\tilde{X}_t$ is the process defined in (3.7). Similarly,

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t \varphi_j(t) dt \xrightarrow{a.s. \ T \to \infty} (1-s^0) \int_{0}^{T} (\tilde{h}_j(t))^2 \varphi_j(t) dt$$

(3.14)

and

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t^2 dt \xrightarrow{a.s. \ T \to \infty} \left(1-s^0\right) \left(\int_{0}^{T} (\tilde{h}_j(t))^2 dt + \frac{\sigma^2}{2d^2}\right).$$

(3.15)

Using (3.10), the following properties hold:

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t \varphi_j(t) dt \xrightarrow{a.s. \ T \to \infty} 0,$$

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t^2 dt \xrightarrow{a.s. \ T \to \infty} 0,$$

and

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t^2 dt \xrightarrow{a.s. \ T \to \infty} 0.$$

Hence, it follows that

$$\frac{1}{T} Q_{(0,\tilde{T})} \xrightarrow{a.s. \ T \to \infty} s^0 \Sigma_1,$$

(3.16)

$$T Q_{(0,\tilde{T})}^{-1} \xrightarrow{a.s. \ T \to \infty} \frac{1}{s^0} \Sigma_1^{-1},$$

(3.17)

$$\frac{1}{T} \int_{0}^{T} \tilde{X}_t \varphi_j(t) dt \xrightarrow{a.s. \ T \to \infty} 0,$$

(3.18)

and

$$T Q_{(\tilde{T},T)}^{-1} \xrightarrow{a.s. \ T \to \infty} \frac{1}{1-s^0} \Sigma_2^{-1},$$

(3.19)

where

$$\Sigma_1 = \begin{bmatrix} I_p & \Lambda_1 \\ \Lambda_1' & w_1 \end{bmatrix} \quad \text{and} \quad \Sigma_2 = \begin{bmatrix} I_p & \Lambda_2 \\ \Lambda_2' & w_2 \end{bmatrix}$$

with $\Lambda_i = \left(\int_{0}^{1} \tilde{h}_j(t) \varphi_1(t) dt, ..., \int_{0}^{1} \tilde{h}_j(t) \varphi_p(t) dt\right)$ and $w_i = \int_{0}^{1} (\tilde{h}_j(t))^2 dt + \frac{\sigma^2}{2d^2}, \ i = 1, 2$. Furthermore, it follows from Proposition 2.2.6 in Zhang (2015) that both $\Sigma_1$ and $\Sigma_2$ are positive definite provided that Assumptions 1–2 hold.

### 3.2. New results for the analysis of asymptotic properties

Based on the established results in Subsection 3.1, we provide two propositions which are useful in illustrating the asymptotic properties of the estimator for the change point.

**Proposition 3.2.** For any $\eta \in (0, s^0]$, we have

$$\frac{1}{T} Q_{(0,\tilde{T})} \xrightarrow{a.s. \ T \to \infty} \eta \Sigma_1,$$

(3.20)

and

$$\frac{1}{T} Q_{(\tilde{T},T)} \xrightarrow{a.s. \ T \to \infty} (s^0 - \eta) \Sigma_1,$$

(3.21)

and

$$\frac{1}{T} Q_{(\tilde{T},T)} \xrightarrow{a.s. \ T \to \infty} (s^0 - \eta) \Sigma_1 + (1-s^0) \Sigma_2.$$

(3.22)

**Proof.** Result (3.20) follows directly from (3.17) with the upper bound of the integrals reduces from $s^0 T$ to $\eta T$. Similarly, (3.21) follows directly from (3.17) with the lower bound of the integrals increases from 0 to $\eta T$. Finally, (3.22) could be obtained by combining (3.20) and (3.21).

**Proposition 3.3.** For any $\eta \in (s^0, 1]$, we have

$$\frac{1}{T} Q_{(0,\tilde{T})} \xrightarrow{a.s. \ T \to \infty} (1-\eta) \Sigma_2,$$

(3.23)

$$\frac{1}{T} Q_{(\tilde{T},T)} \xrightarrow{a.s. \ T \to \infty} (\eta - s^0) \Sigma_2,$$

(3.24)

and

$$\frac{1}{T} Q_{(0,\tilde{T})} \xrightarrow{a.s. \ T \to \infty} s^0 \Sigma_1 + (\eta - s^0) \Sigma_2.$$

(3.25)
Proof. Result (3.23) follows directly from (3.18) with the lower bond of the integrals increases from \( s^0T \) to \( \eta T \). Similarly, (3.24) follows directly from (3.18) with the upper bond of the integrals reduces from \( T \) to \( \eta T \) and (3.25) is established by combining (3.23) and (3.24).

Moreover, for the case where the change point is unknown, Zhang (2015) assumed that there exists a consistent estimator of the unknown change point and derives the same asymptotic properties for the drift parameters based on the consistent estimator assumption of a change point.

4. Two methods in the estimation of the change point

We develop the least sum of squared error (LSSE) and maximum log-likelihood (MLL) methods to yield an estimator for the unknown change point \( \tau \), and investigate its consistency under these two methods.

4.1. Least sum of squared error method

This subsection first introduces the LSSE method then studies the consistency of the proposed estimator. To calculate the residuals, we apply the Euler-Maruyama discretisation method to (2.1). Consider a partition \( 0 = t_0 < \ldots < t_n = T \) on a given time period \([0, T]\) with a constant increment \( \Delta_t = t_{i+1} - t_i \). Hence, \( Y_i = X_{t_{i+1}} - X_{t_i} \) and \( Z_i = (\varphi_1(t_i), \ldots, \varphi_p(t_i), -X_0)(\Delta t) \), and the discretized process is given by

\[
Y_i = Z \theta + \epsilon_i, \quad t_i \in [0, T],
\]

where \( \epsilon \) is the error term given by \( \sigma \sqrt{\Delta t} \mathcal{N} \), and \( N \) is the standard normal term. In this case, we could use the least-squared (LS) method to estimate the change point. The details of the LS method will be discussed in the next section. Based on (4.1), let \( \tau^0 \) be the exact value of the unknown change-point \( \tau \). Then, \( \tau^0 \) can be estimated using the least sum of squared errors (SSE) method described as

\[
\hat{\tau} = \arg \min_{\tau} \sum_{t_i \in [0, T]} (Y_i - Z \tilde{\theta}(\tau))^2 (Y_i - Z \tilde{\theta}(\tau)),
\]

where

\[
SSE(\tau) = \sum_{t_i \in [0, T]} (Y_i - Z \tilde{\theta}(\tau))^2 (Y_i - Z \tilde{\theta}(\tau))
\]

and \( \tilde{\theta}(\tau) \) is the estimator of \( \theta \) with the change point given by \( \tau \). More precisely, from Zhang (2015), \( \hat{\theta} = (\hat{\theta}^{(1)}, \hat{\theta}^{(2)}) \) where

\[
\hat{\theta}^{(1)} = Q^{-1} \hat{R}^{-1}(0, \hat{\tau}) \quad \text{and} \quad \hat{\theta}^{(2)} = Q^{-1} \hat{R}^{-1}(\hat{\tau}, T).
\]

Consistency of the proposed estimator

Under Assumptions 1–2, \( \sum_{t_i \in [0, \tau^0]} Z'Z_i \) and \( \sum_{t_i \in [\tau^0, T]} Z'Z_i \), the respective discretised versions of \( Q_{(0, \tau^0]} \) and \( Q_{[\tau^0, T)} \) are both positive definite with probability 1 provided that the base functions \( \{\varphi_i(t), i = 1, \ldots, p\} \) are incomplete. Moreover, it follows from Proposition 2.2.6 in Zhang (2015) that both \( \frac{1}{\Delta t} Q_{(0, \tau^0]} \) and \( \frac{1}{\tau^0 - \tau^0} Q_{[\tau^0, T)} \) converge in probability to some positive definite matrices for large \( T \), and so are their respective discretised versions. Hence, for large \( T \), it is reasonable to impose a useful assumption in proving the consistency of the estimator of the change point.

Assumption 3. Suppose that there exists an \( L_0 > 0 \) such that for all \( L > L_0 \) the minimum eigenvalues of \( \frac{1}{L} \sum_{t_i \in [\tau^0, \tau^0 + L]} Z'Z_i \) and of \( \frac{1}{L} \sum_{t_i \in [\tau^0 - L, \tau^0]} Z'Z_i \), as well as their respective continuous-time versions \( \frac{1}{L} Q_{[\tau^0, \tau^0 + L]} \) and \( \frac{1}{L} Q_{[\tau^0 - L, \tau^0]} \), are all bounded away from 0.

For more details about the above assumption, reader is referred to Perron and Qu (2006) (see also Chen and Nkurunziza (2015)). Below are two propositions pertinent to the consistency of the rate of change point specified by \( \hat{\tau} = \bar{\tau} / T \), where \( \bar{\tau} \) is given by (4.2).

Proposition 4.1. Suppose that \( \theta^{(1)} - \theta^{(2)} \), the shift in the drift parameters, is of fixed non-zero magnitude independent of \( T \). Then, under Assumptions 1–3, \( \frac{s - s^0}{T} \xrightarrow{T \to 0} 0 \).

Proposition 4.2. Suppose the conditions in Proposition 4.1 hold. Then, for every \( \epsilon > 0 \), there exists a \( C > 0 \) such that for large \( T \), \( P(T | s - s^0 | > C) < \epsilon \).
The proofs of Propositions 4.1 and 4.2 are provided in Appendix A. Proposition 4.1 shows that the estimated rate \( \hat{s} \) is consistent for \( s^0 \) and Proposition 4.2 shows that the rate of convergence is \( T \). From these two propositions, we conclude that the proposed estimator satisfies the consistency assumption required in Zhang (2015). Hence, it follows from Corollary 2.3.1 in Zhang (2015) that

\[
\sqrt{T}(\hat{\theta}(\hat{t}) - \theta^0) \xrightarrow{D} \sqrt{\frac{1}{T}} N(0, \sigma^2 \hat{\Sigma}^{-1}), \tag{4.4}
\]

where \( \hat{\Sigma}^{-1} = \text{diag}\left\{ \frac{1}{\sqrt{T}} \Sigma_1^{-1}, \frac{1}{\sqrt{T}} \Sigma_2^{-1} \right\} \) and \( \hat{t} \) and \( \hat{\theta} \) are obtained from 4.3.

**Remark 1.** Note that in this paper, we focus on the case where the shift in drift parameters \( (\theta^1) \) and \( (\theta^2) \) indicated in (2.1) is independent of time \( T \). However, in reality we may encounter the case where the shift is time-dependent, and in particular, as \( T \) tends to infinity, the shift may shrink towards 0 at rate \( v_T \), i.e., \( (\theta^1) - \theta^2 = Mv_T \), where \( M \) is independent of \( T \) and \( v_T \xrightarrow{T \to \infty} 0 \). In this case, the validity of Proposition 4.1 and Proposition 4.2 depends on the speed \( v_T \). In fact, using similar arguments as in the proofs of these two propositions (see Appendix A), one may show that if \( v_T \xrightarrow{T \to \infty} 0 \) and \( T^{1/2-r}v_T \xrightarrow{T \to \infty} \infty \) for some \( 0 < r < 1/2 \), then under Assumptions 1–3, we have (i) \( \hat{s} - s^0 \xrightarrow{p} 0 \) and (ii), for every \( \epsilon > 0 \), there exists a \( C > 0 \) such that for large \( T \), \( P(\sqrt{T} |s - s| > C) < \epsilon \). (See Remark 3 in Appendix A).

### 4.2. Maximum log-likelihood method

We introduce the maximum log-likelihood (MLL) method pertinent to the study of the consistency of the proposed estimator. By Theorem 7.6 in Lipster and Shiryaev (2001), the log-likelihood function of (2.1) (see also Dehling, et al., (2010) and Zhang, (2015)) is

\[
\log L^*((0, T), \theta) = \frac{1}{\sigma^2} \int_0^T S(\theta, t, X_t)dt - \frac{1}{2\sigma^2} \int_0^T S^2(\theta, t, X_t)dt.
\]

When a change point \( \tau \) exists, the log-likelihood function is

\[
\log L(\tau, \theta) = \log L^*((0, \tau), (\theta^1)) + \log L^*((\tau, T), (\theta^2)). \tag{4.5}
\]

Based on this log likelihood function, an alternative method to estimate the unknown change point is using the maximum of the log likelihood function. That is,

\[
\hat{\tau} = \arg \max_{\tau} \log L(\tau, \hat{\theta}(\tau)), \tag{4.6}
\]

or equivalently

\[
\hat{\tau} = \arg \min_{\tau} -2 \log L(\tau, \hat{\theta}(\tau)), \tag{4.7}
\]

where \( \hat{\theta} \) is the MLE of \( \theta \) based on \( \hat{\tau} \).

### Consistency of the proposed estimator

To investigate the consistency behavior of the proposed estimator \( \hat{\tau} \) obtained from (4.6), we update Assumption 3 to the following version:

**Assumption 4.** Suppose that there exists an \( L_{\theta} > 0 \) such that under Assumption 1–3, for all \( L > L_{\theta} \) the minimum eigenvalues of the following two symmetric matrices \( \frac{1}{2\pi}[Q_{(\sigma,\tau)}^{-1}Q_{(\sigma,\tau+L)}^{-1}Q_{(\sigma,\tau+L)} \times Q_{(\sigma,\tau+L)}^{-1}Q_{(\sigma,\tau)}] \) and \( \frac{1}{2\pi}[Q_{(\sigma,\tau)}^{-1}Q_{(\sigma,\tau-L)}^{-1}Q_{(\sigma,\tau-L)} \times Q_{(\sigma,\tau-L)}^{-1}Q_{(\sigma,\tau)}] \) are all bounded away from 0.

Then, similar to the LSSE method, for the estimator \( \hat{\tau} \) given by (4.6), we also provide two propositions below regarding the consistency of \( \hat{s} \).

**Proposition 4.3.** Suppose that \( (\theta^1) - (\theta^2) \), the shift in the drift parameters, is of fixed non-zero magnitude independent of \( T \). Then, under Assumptions 1–2 and Assumption 4, \( \hat{s} - s^0 \xrightarrow{p} 0 \).

The next proposition gives the rate of convergence, \( T \), for \( \hat{\tau} \).

**Proposition 4.4.** Under the same conditions of Proposition 4.3, we have that for every \( \epsilon > 0 \), there exists a \( C > 0 \) such that for large \( T \), \( P(T|s - s| > C) < \epsilon \).
The proofs of Propositions 4.3 and 4.4 are provided in Appendix A. Proposition 4.3 establishes that the estimated rate \( \hat{\tau} \) is consistent for \( \tau^0 \) and Proposition 4.4 shows that the rate of convergence is \( T \). Moreover, in case the shift in the drift parameters is of shrinking magnitude, the discussions in Remark 1 also hold for this case. Propositions 4.3 and 4.4 imply that the proposed estimator satisfies the consistency assumption required in Zhang (2015). Thus, the asymptotic normality in (4.4) also holds when \( \hat{\tau} \) are obtained from (4.6).

**Remark 2.** To see the connection between equations (4.6) and (4.2), one may apply the Riemann sum approximation with increment \( \Delta \) to approximate the integrals inside the log-likelihood function \( \log(\sigma) \) specified in (4.3). The result of the approximation is of the form \( \sum_{i=0}^{T} (\hat{\theta}(\tau)^{V}(X_{t_{i+1}} - X_{t_i})) \). Furthermore, if the increment \( \Delta \) is same as that in the LSSE method, we have \( X_{t_{i+1}} - X_{t_i} = Y_i \) and \( V(t) = Z_i/\Delta \). Then, after some algebraic computations, such approximation can be transformed to \( \sum_{i=0}^{T} (\hat{\theta}(\tau)^{V}(Y_i)^2 / \Delta) \). Hence, for an observed process \( X_t, t \in [0, T] \) with same constant \( \Delta \) and known \( \sigma \), (4.2) and the Riemann sum approximation of (4.6) are equivalent. This finding will also be confirmed by the simulation results highlighted in Section 6.

### 5. Existence of a change point

In Section 4, we introduced two estimation methods for the case where the existence of the single change point is affirmative, that is, the number of change points is known to be 1. In this section, we shall deal with the extended change-point problem in which the number of change points may be either 0 or 1. In this case, it is of interest to test the existence of the change point and to determine its exact location if it exists.

One popular methodology in the change-point literature in detecting the unknown number of change points is by treating it as a model-selection problem. For instance, note that the existence of the change point in (2.1) also increases the number of drift parameters from \( p + 1 \) to \( 2(p + 1) \). Hence, detecting the existence of change points is equivalent to selecting a statistical model from two candidate models and this could be solved by using the informational approach. This approach deems that the most appropriate model is the one that minimises the log-likelihood-based information criterion

\[
IC(m) = -2\log(L(\hat{\tau}, \hat{\theta})) + (m + 1)h(p)\phi(T).
\]  

(5.1)

In (5.1), \( L(\hat{\tau}, \hat{\theta}) \) is defined in (4.3); \( \hat{\tau} \) is obtained via (4.6) corresponding to each \( m \), where \( m \) is the potential number of change points to be determined (\( m = 0 \) or 1 in this case); \( h(p) = p + 1 \) if there is no change in the diffusion coefficient \( \sigma \) before and after the change point or \( p + 2 \) if there is a change in \( \sigma \) (i.e. \( \sigma = \sigma^{(1)} \) for \( t \in [0, \tau^0] \) and \( \sigma = \sigma^{(2)} \) for \( t \in (\tau^0, T] \) and \( \phi(T) \) is a non-decreasing function of \( T \).

Note that if the number of change points is known, then the term \( (m + 1)h(p)\phi(T) \) is fixed, and (5.1) is equivalent to the maximum log likelihood method introduced in the previous section. The efficiency of the information criterion depends on the choice of the penalty criterion \( \phi(T) \). For example, if \( \phi(T) = 2 \), then (5.1) reduces to the well-known Akaike information criterion (AIC) (1973). However, in practice, a model selected by minimising the AIC may not be asymptotically consistent in terms of the model order; see for example, Schwarz (1978). Many modified versions, thus, were proposed to overcome this problem. One of the modifications is the Schwarz information criterion (SIC) (1978) entails the setting of \( \phi(T) \) as the log transform of the sample size. SIC has been successfully applied to the change-point analysis in the literature, and it gives an asymptotically consistent estimate of the order of the true model. Hence, we only focus on SIC on this particular theoretical development.

Further, it may be of interest to see which of the two penalty criteria we should use: \( \phi(T) = \log(T) \) or \( \phi(T) = \log(T/\Delta) \), where \( \Delta \) is the increment defined in the previous section. Hence, in the ensuing discussion of our examples, we take into account these two criteria. (Note that \( \log T \) is just a special case of \( \log(T/\Delta) = \log(T) - \log(\Delta) \) with \( \Delta = 1 \).

Consider the hypothesis

\[
H_0: \quad m^0 = 0 \quad \text{versus} \quad H_1: \quad m^0 = 1.
\]  

(5.2)

Based on (5.1), the rejection region for the null hypothesis in (5.2) is given by \( IC(m = 0) \geq IC(m = 1) \). Moreover, the asymptotic significant level and power of the above test are investigated via the following results.

**Proposition 5.1.** Suppose Assumptions 1–2 hold. Then, under \( H_0 \) in (5.2),

\[
\lim_{T \to \infty} P(\text{IC}(m = 0) \geq \text{IC}(m = 1)) = 0.
\]

Moreover, under \( H_1 \),

\[
\lim_{T \to \infty} P(\text{IC}(m = 0) > \text{IC}(m = 1)) = 1.
\]

The proof of Proposition 5.1 is presented in Appendix B.

Let \( \hat{m} = \arg \min_{m \in \{0, 1\}} IC(m) \) with \( \phi(T) = \log T \) or \( \log(T/\Delta) \). We then have the following.

10
Corollary 5.1. Under Assumptions 1–2 and \( \hat{n} \to n^{0} \overset{P}{\longrightarrow} 0 \).

The proof of Corollary 5.1 is immediate from Proposition 5.1.

For a fixed \( \Delta_t \) and large \( T \), Corollary 5.1 shows that the two criteria, \( \log(T) \) and \( \log(T/\Delta_t) \), lead to asymptotically consistent estimate of the number of change points. For small \( T \), we use Monte-Carlo simulation to compare the performance of these two criteria. Simulation results indicate that it would be more appropriate to use \( \phi(T) = \log(T/\Delta_t) \) when \( T \) is small as \( \phi(T) = \log T \) tends to over-estimate the number of change points, i.e., overfitting the model.

6. Numerical demonstrations

In this numerical work, we use in Subsection 6.1 the Monte-Carlo simulation technique to evaluate the performance of the (i) two estimation methods proposed in (4.2) and (4.6) in detecting the unknown location of a change point assumed to already exist, and (ii) method in (5.1) for testing the existence of a change point. In Subsection 6.2, we implement the above methods on some observed financial market data as illustrate the various implementation details.

6.1. Monte-Carlo simulation study

Our simulation considers two different scenarios. In the first scenario, we study the performance of the proposed methods under a classical OU process. In the second scenario, the performance evaluation of the proposed methods is applied to a periodic mean-reverting OU process. Each scenario consists of 1000 iterations. In each iteration, we first generate a desired simulated process based on the Euler-Maruyama discretisation scheme given a period \( T \) and pre-assigned “true” parameters such as the coefficients and rate of change point. Next, we estimate and record the rate of change points by applying (4.2) and (4.6) on the simulated process as well as the number of change points estimated by (5.1). To investigate the performance of (5.1), assuming there is no change point, we re-generate a simulated process with no change point and apply (5.1) to estimate and record again the number of change points. After 1000 iterations, we analyse the performance of the proposed methods based on the recorded results.

6.1.1. Simulation setup

Scenario 1: Classical OU process

Two classical OU processes are considered with stochastic dynamics

\[
dX_t = \begin{cases} 
(0.08 - 0.1X_t) dt + 0.2dW_t, & \text{if } 0 < t < 0.5T \\
(2.5 - 1X_t) dt + 0.2dW_t, & \text{if } 0.5T < t < T.
\end{cases} \tag{6.1}
\]

Equation (6.1) includes one change point occurring at \( t^0 = 0.5T \) (\( \phi^0 = 0.5 \)). This process is generated to determine the performance of the methods proposed in (4.2) and (4.6).

When there is one change point, we study the performance of (5.1) by considering the SDE

\[
dX_t = (2.5 - X_t) dt + 0.2dW_t, \quad 0 < t < T. \tag{6.2}
\]

Scenario 2: Periodic-mean reverting OU process

For this scenario, we consider a mean-reverting OU process, with 2-dimensional periodic incomplete orthogonal set of functions \( \{1, \sqrt{2}\cos\left(\frac{\pi t}{2\Delta_t}\right)\} \), given by

\[
dX_t = \begin{cases} 
0.08 + 0.02 \sqrt{2}\cos\left(\frac{\pi t}{2\Delta_t}\right) - 0.1X_t dt + 0.2dW_t, & \text{if } 0 < t < 0.5T \\
2.5 + 1.2 \sqrt{2}\cos\left(\frac{\pi t}{2\Delta_t}\right) - 1X_t dt + 0.2dW_t, & \text{if } 0.5T < t < T,
\end{cases} \tag{6.3}
\]

where \( \Delta_t = t_{i+1} - t_i \) is the increment in the given time period \([0, T]\).

Similarly, we study the performance of (5.1), under the assumption that there is no change point, using the SDE

\[
dX_t = \left(2.5 + 1.2 \sqrt{2}\cos\left(\frac{\pi t}{2\Delta_t}\right) - X_t\right) dt + 0.2dW_t, \quad 0 < t < T. \tag{6.4}
\]

We choose \( T = 5, 10, 20 \) and 50, and \( \Delta_t = 1/252 \) and the starting point \( X_0 = 0.05 \). Simulated sample paths for the processes (6.1)–(6.4) with different time periods (\( T = 5 \) and 50) are shown in Figures [1–4].
Scenario 1, $m^2=1, T=5$

Scenario 1, $m^2=1, T=50$

Figure 1: Sample series for (6.1) under scenario 1 with one change point

Scenario 1, $m^2=0, T=5$

Scenario 1, $m^2=0, T=50$

Figure 2: Sample series for (6.2) under scenario 1 without a change point
Figure 3: Sample series for (6.3) under scenario 2 with one change point.

Figure 4: Sample series for (6.4) under scenario 2 without a change point.
6.1.2. Discussion of simulation results

**Estimating the rate of change point**
We first look at the performance of (4.2) and (4.6) in estimating the corresponding rate of change point in (6.1) and (6.3), respectively. Note that in each iteration, we apply (4.2) and (4.6) to the same simulated process; hence, results from these two methods are expected to be close to each other. The mean and mean-squared error (MSE) of the estimated rate of change point \( \hat{s} \) for (6.1) based on LSSE and MLL methods are summarised in Table 1, and the results for (6.3) are displayed in Table 2.

To illustrate further the simulated results, the corresponding histograms for \( \hat{s} \) in (6.1) are depicted in Figure 5 under scenario 1, and in Figure 6 under scenario 2.

**Estimating and testing the number of change points**
Here, we evaluate the performance of the proposed method by utilising the percent accuracy (PA) metric defined by

\[
PA(m^0) = \frac{1}{1000} \sum_{i=1}^{1000} I(\hat{m}_i = m^0) \times 100\%,
\]

where \( \hat{m}_i \) is the estimated number of change points in the \( i \)th iteration. Note that

\[
1 - PA(0) = \frac{1}{1000} \sum_{i=1}^{1000} I(C(\hat{m}_i = 0) \geq IC(\hat{m}_i = 1)),
\]

which is the empirical significance level. Further,

\[
PA(1) = \frac{1}{1000} \sum_{i=1}^{1000} I(C(\hat{m}_i = 0) < IC(\hat{m}_i = 1)),
\]

which is the empirical power of the proposed test.

As stated in the previous subsection, we aim to assess the performance of (5.1); and for this purpose we use the criteria \( \phi(T) = \log T \) and \( \phi(T) = \log(T/\Delta_t) \). Moreover, for \( h(p) \), we also consider two cases: \( h(p) = p + 1 \) and \( h(p) = p + 2 \) for whether or not there is a potential change in the diffusion coefficient \( \sigma \) specified in (2.1). Consequently, we make a comparison on the basis of four penalty criteria: \( (p + 1) \log T \), \( (p + 2) \log T \), \( (p + 1) \log(T/\Delta_t) \) and \( (p + 2) \log(T/\Delta_t) \). The results are reported in Tables 3–6 for each of the scenarios.

From Tables 1 and 2 as well as the plotted histograms, we see that both proposed methods (4.2) and (4.6) estimate very accurately the exact rate of change point \( \hat{s} = 0.5 \). In addition, as the time period \( T \) increases from 10 to 50, the MSEs of the two estimators decrease. These outcomes confirm the theoretical findings for the asymptotic consistency of our two proposed methods.
Figure 5: Histogram of $\hat{s}$ for Scenario 1 (6.1)
Figure 6: Histogram of $\hat{s}$ for scenario 2, (6.3)

Table 3: Empirical power of the test (in %), under scenario 1, (6.1)

| $T$  | $(p + 1) \log T$ | $(p + 2) \log T$ | $(p + 1) \log(T/\Delta)$ | $(p + 2) \log(T/\Delta)$ |
|------|------------------|------------------|---------------------------|---------------------------|
| $T=5$ | 100              | 100              | 98.9                      | 96.5                      |
| $T=10$ | 100              | 100              | 99.4                      | 97.3                      |
| $T=20$ | 100              | 100              | 99.7                      | 97.5                      |
| $T=50$ | 100              | 100              | 99.6                      | 97.2                      |
We apply the estimation methods (4.2), (4.6) and (5.1) to two different mean-reverting OU processes with one change point. This suggests that it would be more appropriate in this case to use a penalty criterion that is larger than $\phi(T) = log(T/\Delta_t)$. When there is no change point, Tables 4 and 5 reveal that the empirical significance levels, under different penalty criteria, decrease as $T$ increases. These results also imply that our proposed method is asymptotically consistent.

Amongst the 4 penalty criteria, we observe that when $\phi(T) = log(T)$, the empirical significance level is relatively high when $T$ is small, while the empirical significance level decreases when we change $h(p)$ from $p + 1$ to $p + 2$. This outcome tells us that it would be more appropriate in this case to use a penalty criterion that is larger than $h(p)\phi(T) = (p + 1)log T$ for better estimation. On the other hand, when using $\phi(T) = log(T/\Delta_t)$, the performance is significantly improved compared to that of $\phi(T) = log T$. In both scenarios, one could see that when the time period is small ($T=5$ and $T=10$), the empirical significance level of the proposed method is relatively high when using $\phi(T) = log T$, but decreases to almost 0% when $\phi(T) = log(T/\Delta_t)$.

Overall, based on the results in Tables 3-6 for different cases, we find that for a bigger $T$, $\hat{m}$ obtained via (5.1) under four different penalty criteria all perform consistently in estimating the number of change points. However, when $T$ is small, the performance based on the criterion $h(p)\phi(T) = (p + 1)log(T/\Delta_t)$ is efficient and stable vis-à-vis the other criteria in each case. This suggests that $h(p)\phi(T) = (p + 1)log(T/\Delta_t)$ is appropriate for this simulation study.

### 6.2. Implementation on observed financial market data with discussion

We apply the estimation methods (4.2), (4.6) and (5.1) to two different financial market data series. For each series, we fit the process with the following two different mean-reverting OU processes with one change point.

\[
\begin{align*}
    dX_t &= \begin{cases} 
    (\mu_1^{(1)} - d^{(1)} X_t) dt + \sigma dW_t, & \text{if } 0 < t < sT \\
    (\mu_1^{(2)} - d^{(2)} X_t) dt + \sigma dW_t, & \text{if } sT < t < T 
    \end{cases}, \\
    dX_t &= \begin{cases} 
    (\mu_1^{(1)} + \sqrt{2} \cos(\frac{\pi t}{2T})) \mu_1^{(1)} - d^{(1)} X_t) dt + \sigma dW_t, & \text{if } 0 < t < sT \\
    (\mu_1^{(2)} + \sqrt{2} \cos(\frac{\pi t}{2T})) \mu_1^{(2)} - d^{(1)} X_t) dt + \sigma dW_t, & \text{if } sT < t < T 
    \end{cases}.
\end{align*}
\]

where $X_t$ is the target of interest (i.e., spot price, log-transformed spot price, daily return, etc.) at time $t$. The no-change point versions of (6.5) and (6.6) are

\[
\begin{align*}
    dX_t &= (\mu_1 - aX_t) dt + \sigma dW_t, & \text{if } 0 < t < T, \\
    dX_t &= \left(\mu_1 + \sqrt{2} \cos\left(\frac{\pi t}{2T}\right)\right) \mu_1 - aX_t) dt + \sigma dW_t, & \text{if } 0 < t < T.
\end{align*}
\]
For (6.5) and (6.6), we apply (4.2) and (4.6) to estimate the unknown change point, whilst for (6.7) and (6.8), we train the MLE of drift parameters based on the entire time period. Then, we use (5.1) to test the existence of a change point. In our formulation \( \sigma \) is assumed to remain unchanged for the entire time period, and thus it may estimated using the data’s realised volatility, i.e., \( \hat{\sigma} = (\sum_{t \in [0,T]} (X_{t+1} - X_t)^2 / T)^{1/2} \). Alternatively, one may fit the data series to the model, take the standard error of the residuals and then divide it by \( \sqrt{\Delta t} \) (see Smith (2010)).

When \( \sigma \) is time-dependent, EWMA and GARCH-type volatility estimation methods may be used. However, under this situation the MLE and related asymptotic properties established in Dehling, et al. (2010) as well as the asymptotic properties derived in this paper may need re-evaluation as they are all based on the time-independent assumption of the diffusion coefficient \( \sigma \). In this paper, we consider \( \sigma \) to be time-independent and after the estimated results are obtained, the most suitable model is chosen as the one yielding the least SIC value. In addition, we also report the log likelihood for comparison. To this end, we let \( L_L0 \) and \( L_L1 \) denote the log likelihood under \( H_0 \) and \( H_1 \), respectively.

### 6.2.1. Application to West Texas Intermediate Cushing crude oil spot price

The first data set is the time series of West Texas Intermediate Cushing crude oil spot prices, which was first described in Subsection 1.2.1. Our interest in this data set is justified by the fact that, as mentioned in Subsection 1.2.1, it is often being considered as a benchmark in oil pricing. Furthermore, the modelling of and point-change detection in commodity prices are important in the valuation of commodity derivatives and risk management of portfolios with large commodity holdings.

For our preliminary attempt, we set the WTI crude oil spot price to be our target of interest. To fit the model, we choose \( T = 4 \) and so \( \Delta t = 4/1008 \). With the data fitted to the two candidate models using the proposed methods, we display the results shown in Table 7 and Figure 7.

| Model | LSSE method | MLL method | \( \hat{m} \) | \( LL_1 \) | \( LL_0 \) | IC(\( m = 1 \)) | IC(\( m = 0 \)) |
|-------|--------------|------------|-------|--------|--------|-------------|-------------|
| (6.5) | 2014-09-26   | 2014-09-26 | 1     | 11.89  | 0.72   | 3.87        | 12.39       |
| (6.6) | 2014-09-26   | 2014-09-26 | 1     | 9.96   | 3.99   | 9.96        | 12.76       |

![Figure 7: WTI Cushing crude oil spot prices (09 November 2011–09 November 2015)](image)

Looking at Table 7 and Figure 7 one can see that the value of the log likelihood increases as the number of the coefficients in the model increases. Further, both candidate models confirm the existence of a change point (\( \hat{m} = 1 \)) during this time period. Under both models, the detected change point is the same (i.e., 26 September 2014) for the proposed methods. On the other hand, despite the log-likelihood comparison showing that the periodic mean-reverting model (6.6) produces higher log likelihood than the classical OU process with change point (6.5), the SIC, nonetheless, suggests that (6.5) is more appropriate than (6.6) for this data series.

As suggested in Chen (2010), we also analyse the log-transformed WTI crude oil spot prices. We examine the log-transformed WTI crude oil spot prices as our target of interest and re-apply the proposed techniques. The results are shown in Table 8.
and Figure 8. It is worth noting that the detected change points for this log-transformed spot prices are still the same (i.e., 26 September 2014), as well as the behavior of log-likelihood (increase as the number of coefficients in the model increases); although, this time around, the results based on (6.6) fail to pass the test on the existence of a change point ($m = 0$). Judging from the SIC numbers, model (6.5) is again better than model (6.6). This suggests that (6.5), with the change point occurring on 26 September 2014, is more suitable for both the WTI Cushing crude oil price data and its log-transformed series.

Table 8: Change point detection for the log-transformed WTI crude oil prices

| Model | LSSE method | MLL method | $m$ | $L_L$ | $L_{L_0}$ | $JC(m = 1)$ | $JC(m = 0)$ |
|-------|-------------|------------|-----|-------|-----------|-------------|-------------|
| (6.5) | 2014-09-26  | 2014-09-26 | 1   | 8.15  | 0.82      | 11.37       | 12.18       |
| (6.6) | 2014-09-26  | 2014-09-26 | 0   | 13.68 | 4.26      | 14.12       | 12.20       |

Based on our primary statistics of interest, defined here as the estimated change point $\hat{\tau}$ and the associated MLE $\hat{\theta}^{(1)}$ and $\hat{\theta}^{(2)}$ obtained from the proposed methods, we use model (6.5) to generate a simulated crude oil price data set and log-transformed crude oil price data series. Additionally, we also generate a simulated data series based on (6.7) for comparison. The two simulated series are presented side-by-side in Figure 9.

Figure 9: Simulated series of WTI Cushing crude oil spot price (09 November 2011–09 November 2015)

By comparing the simulated series in Figures 9 and 10 to the original series (shown in Figures 7 and 8), we see that the simulated series generated by (6.5), with the change point occurring on 26 September 2014, is closer to the original series than the one generated by (6.7). This confirms the efficiency of the proposed methods for this series.
6.2.2. Application to XAU currency

We apply as well the proposed methods to the XAU currency data, which was described in Subsection 1.2.2. This data set refers to the time-series of prices, in US dollars, for a troy ounce of gold. Our interest in this kind of data set is motivated by the pricing of currency swaps, futures and options.

Figure 11 shows that the trend of XAU currency series changed over time. As in the previous study, we take both the XAU currency and its logarithm as our targets of interest. To fit the data with the candidate models, we choose $T = 15$ and $\Delta t = 15/3913$. The results for the XAU currency are depicted in Table 9 and Figure 11 whilst the results for the log-transformed XAU currency are shown in Table 10 and Figure 12.

Table 9: Change-point detection for XAU currency (15 years)

| Model | LSSE method | MLL method | $\hat{m}$ | $\mathcal{L}_1$ | $\mathcal{L}_0$ | $IC(m = 1)$ | $IC(m = 0)$ |
|-------|-------------|------------|---------|--------------|--------------|-------------|-------------|
| 6.5   | 2013-04-08  | 2013-04-08 | 1       | 12.62        | 1.43         | 7.83        | 13.67       |
| 6.6   | 2013-04-08  | 2013-04-08 | 0       | 13.31        | 1.81         | 23.01       | 21.18       |

Table 10: Change point detection for the log-transformed XAU currency (15 years)

| Model | LSSE method | MLL method | $\hat{m}$ | $\mathcal{L}_1$ | $\mathcal{L}_0$ | $IC(m = 1)$ | $IC(m = 0)$ |
|-------|-------------|------------|---------|--------------|--------------|-------------|-------------|
| 6.5   | 2011-08-19  | 2011-08-19 | 0       | 7.08        | 3.25         | 18.92       | 10.04       |
| 6.6   | 2011-08-19  | 2011-08-19 | 0       | 7.41        | 3.46         | 34.80       | 17.89       |
For the original XAU currency, one can see that log-likelihood increases as the number of coefficients in the model increases. Further, \( \hat{m} = 0 \) successfully detects one change point on 08 April 2013, whilst \( \hat{m} = 0 \) fails to detect the change point (\( \hat{m} = 0 \)). However, the SIC comparison shows that the classical OU process (SIC= 7.83) is more appropriate than the periodic mean-reverting model (SIC= 21.18); we, therefore, select (6.5) with the change point on 08 April 2013 as the suitable model for this series.

For the log-transformed XAU currency, Figure 12 illustrates visually that the series is smoother than the original series (see Figure 11), and the potential change in the series becomes less clear. Applying the proposed methods, both (6.5) and (6.6) detect the same change point on 19 August 2011, which is the time when the log-transformed XAU currency almost reaches the highest value. Although the comparison of log-likelihood functions indicates that imposing a change point in the model can produce higher log-likelihood and (6.5) is still more suitable than (6.6) in terms of the SIC, both models fail to pass the test for the existence of change point (\( \hat{m} = 0 \)). These results suggest that for this log-transformed data series, imposing a change point into the model is not as efficient as compared to the original XAU currency series.

Similar to the previous study, we also generate, employing the estimated values of the primary statistics of interest, some simulated series based on (6.5) and (6.6) for both XAU currency and its log transform. The results are given in Figure 13 for the original XAU currency and 14 for the log-transformed XAU currency, respectively.

For the original XAU currency, the comparison shows that the simulated series generated by (6.5) with the change point on 08 April 2013 is closer to the original series, especially around the location where the change point happens; this is in contrast to the model without a change point. This result confirms the efficiency of employing the change-point process (6.5) in improving the estimation of this series. However, the change in the log-transformed series is not clear as the difference between the two simulated series becomes small; they are both close to the original log-transformed series. This means that there may be no need to impose a change point for this log-transformed series; this is because the improvement is not as significant to the one obtained in the original series.
To probe matters on this series further, we change the starting date of the data series to 04 November 2008. This reduces the time period from 15 years to 7 years, and one can see from Figure 15 that the XAU currency levels in this time period are all higher than $700. We re-apply the methods to the XAU currency data and its log-transformed series. Table 11 and Figure 15 show the results for the original XAU currency, and Table 12 and Figure 16 display the results for the log-transformed XAU currency.

Table 11: Change-point detection for XAU currency (7 years)

| Model | LSSE method | MLL method | $\hat{m}$ | $\hat{LL}_1$ | $\hat{LL}_0$ | $TIC(m = 1)$ | $TIC(m = 0)$ |
|-------|-------------|------------|----------|-------------|-------------|--------------|--------------|
| 6.5   | 2013-04-08  | 2013-04-08 | 0        | 9.26        | 2.28        | 11.50        | 10.47        |
| 6.6   | 2013-04-08  | 2013-04-08 | 0        | 9.62        | 2.56        | 25.80        | 17.40        |

As one can see from the results, for the original XAU currency, the detected change point based on (4.2) and (4.6) in both models are still the same as in the 15 years’ time period, suggesting the consistency of the proposed methods. Further, the comparisons of log-likelihood suggest that increasing the number of coefficients in the model are useful in producing higher log-likelihood. This finding is consistent with the previous study. However, after applying (5.1) to test the existence of change...
Table 12: Change-point detection for the log-transformed XAU currency (7 years)

| Model | LSSE method | MLL method | $m$ | $\mathcal{L}_{L_1}$ | $\mathcal{L}_{L_0}$ | $IC(m = 1)$ | $IC(m = 0)$ |
|-------|-------------|------------|-----|----------------------|---------------------|-------------|-------------|
| 6.5   | 2011-08-19  | 2011-08-19 | 0   | 6.06                 | 2.95                | 17.90       | 9.11        |
| 6.6   | 2009-02-23  | 2009-02-23 | 0   | 7.06                 | 3.31                | 30.92       | 15.89       |

Figure 16: XAU currency (04 November 2008–04 November 2015)

Figure 17: Simulated series of XAU currency (04 November 2008–04 November 2015)

Figure 18: Simulated series of log-transformed XAU currency (04 November 2008–04 November 2015)
point, we find that both models fail to pass the test. This tells us that using (6.7) would be enough for modelling the series for this time period.

On the other hand, after applying the log transformation to the XAU currency, the SIC reveals that the model (6.5) is still more complex and elaborate dynamics and stylised features. made and new ideas could be adopted in making further progress in point-change detection involving time series models with for the investigation and development of methodology suited in tackling the multiple-change point problem, which is what we primarily consistent, which in turn aided the design of an efficient implementation algorithm. Our work certainly gives impetus for the development of MLL- and LSSE-based methods in showing the existence or non-existence of a change point and in determining the unknown location whenever such a change point exists. We established the equivalence of the estimators for the change point under the two methods. In addition, we provided conditions so that our estimators for the change point location are asymptotically consistent, which in turn aided the design of an efficient implementation algorithm. Our work certainly gives impetus for the investigation and development of methodology suited in tackling the multiple-change point problem, which is what we commonly encounter in practice. Our research results aim to lay down the groundwork so that further modifications could be made and new ideas could be adopted in making further progress in point-change detection involving time series models with more complex and elaborate dynamics and stylised features.

7. Conclusion

The theoretical results and illustrative examples, involving both simulated and observed data, of this paper were motivated by the practical considerations of point-change detection. Such motivations are driven by applications centred on confirming significant changes in the time-series data so that proper responses and policies could be put in place as in the case of interest rate-setting behaviour of monetary regulatory authority, design of trading strategies in hedging and speculation, appropriate calibration of models in financial product valuation, amongst others. Our main contribution highlighted the development of MLL- and LSSE-based methods in showing the existence or non-existence of a change point and in determining the unknown location whenever such a change point exists. We established the equivalence of the estimators for the change point under the two methods. In addition, we provided conditions so that our estimators for the change point location are asymptotically consistent, which in turn aided the design of an efficient implementation algorithm. Our work certainly gives impetus for the investigation and development of methodology suited in tackling the multiple-change point problem, which is what we commonly encounter in practice. Our research results aim to lay down the groundwork so that further modifications could be made and new ideas could be adopted in making further progress in point-change detection involving time series models with more complex and elaborate dynamics and stylised features.

Appendix A. Proofs of Propositions 4.1, 4.2, 4.3 and 4.4

Appendix A.1. Preliminaries for the proofs of Propositions 4.1 and 4.2

In this section, we let ||A|| denote the Euclidean norm for a vector A and ||B|| = √Trace(B'B) for a matrix B. Further, let ˆui be the residual of the ith element in (4.1) based on the estimated change point ˆτ. That is, ˆui = Yi − Z(1)i ˆθ(1) − Z(2)i ˆθ(2) + u1, j = 1 for 0 < i ≤ ˆτ and τ = ˆτ estimated by (4.2). Similarly, let ˆu0 i be the residual of the ith element in (4.1) based on the exact change point τ0 and the associated MLE of θ(0) denoted by θ(0), j = 1, 2. Without loss of generality, we assume that ˆτ > τ0.

The proofs of Propositions 4.1 and 4.2 both rely on investigating the behaviour of

\[ \phi \left( \sum_{t_i \in [0,T]} ˆu_i' ˆu_i - \sum_{t_i \in [0,T]} ˆu_0^t_{i} ˆu_0^{t_i} \right). \]  

(A.1)

We divide the time period [0, T] involved in (A.1) into 3 sub-intervals: [0, τ0], (τ0, ˆτ] and (ˆτ, T]. Then, by substituting the expressions for ˆui and ˆu0 i into (A.1) and applying the identity \((a + b)^2 = a^2 + 2ab + b^2\) to expand the quadratic error terms, we have

\[ \sum_{t_i \in [0,τ0]} (Z_i(θ(1) - ˆθ(1))^2 + \sum_{t_i \in (τ0, ˆτ]} (Z_i(θ(2) - ˆθ(2))^2 + \sum_{t_i \in (ˆτ, T]} (Z_i(θ(3) - ˆθ(3))^2 \]  

(A.2)

\[ - \phi \sum_{t_i \in [0,τ0]} (Z_iθ(1) - Z_i ˆθ(1))^2 - \phi \sum_{t_i \in (τ0, ˆτ]} (Z_iθ(2) - Z_i ˆθ(2))^2 \]  

(A.3)

\[ + 2\phi \sum_{t_i \in [0,τ0]} u_i Z_i(θ(1) - ˆθ(1)) + \sum_{t_i \in (τ0, ˆτ]} u_i Z_i(θ(2) - ˆθ(2)) \]  

(A.4)

where \( \phi \) is a positive scalar to be defined later, ˆθ(1) = Q−1(0,τ0] ˆR(0,τ0], ˆθ(2) = Q−1(τ0, ˆτ] ˆR(τ0, ˆτ], ˆθ(1,0) = Q−1(0,τ0] ˆR(0,τ0] and ˆθ(2,0) = Q−1(τ0, ˆτ] ˆR(τ0, ˆτ], respectively.
Similarly, to proceed further, we prove the following inequality. Note that by (3.6), sup $\tau$ $\leq 0$ $\frac{2}{\pi}$. This implies that for $0 < \tau < \tau$, given by $\tau = \hat{\tau}$, such that $\tau = \hat{\tau}$, to minimise the SSR, whilst $\tau^*$ is just a particular value in $[0, T]$. Hence, it suffices to show that if the rate of $\tau^*$, given by $\delta^* = \tau^*/T$, can not be consistently estimated by $\hat{\delta} = \hat{\tau}/T$, then $\hat{\tau} > 0$ with positive probability and thus we have a contradiction.

First, note that in case that the rate of the change point $\tau^*$ can not be consistently estimated, then with positive probability there exists an $\eta > 0$ such that $3T - \delta^*T > \eta T > L^0$ for large $T$. In this case, we have $A.2 \geq C_1 ||\theta^1 - \theta^2||^2$ for some $C_1 > 0$ with positive probability (see Bai and Perron (1998), Lemma 2).

To proceed further, we prove the following inequality. Note that by $A.6$, $\sup_{t \leq 0} E((X_t)^2) \leq K_t$ for some $K_t$ with $0 < K_t < \infty$. This implies that for $0 < \tau_1 < \tau_2 \leq T$,

$$\int_{\tau_1}^{\tau_2} E(X_t^2)dt \leq K_t(\tau_2 - \tau_1).$$

Under Assumption 2, it follows from (B.28) in Zhang (2015) that

$$\mathbb{P}\left(\frac{1}{\sqrt{T^2 - \tau_1^2}} \int_{\tau_1}^{\tau_2} |X_t|dW_t| > K^*\right) \leq \frac{E\left(\int_{\tau_1}^{\tau_2} (X_t^2)dt\right)}{\left(\tau_2 - \tau_1\right)(K^*)^2} \leq \frac{E\left(\int_{\tau_1}^{\tau_2} \varphi(t)dW_t\right)^2}{\left(\tau_2 - \tau_1\right)(K^*)^2} \leq \frac{1}{\left(\tau_2 - \tau_1\right)(K^*)^2}. $$

$$\mathbb{P}\left(\frac{1}{\sqrt{T^2 - \tau_1^2}} \int_{\tau_1}^{\tau_2} |\varphi(t)dW_t| > K^*\right) \leq \frac{E\left(\int_{\tau_1}^{\tau_2} \varphi(t)dW_t\right)^2}{\left(\tau_2 - \tau_1\right)(K^*)^2} \leq \frac{1}{\left(\tau_2 - \tau_1\right)(K^*)^2}. $$

Hence, by letting $K^* = \log \delta^* T$ or $K^* = \left(\tau - \tau^0\right)^{\alpha}$ for $0 < \alpha < 1/2$, the above probability tends to 0 as $T$ tends to infinity. This implies that

$$\frac{1}{\sqrt{T^2 - \tau_1^2}} ||R(t, \tau)| = O_p(\log \delta^* T) \text{ or } O_p((\tau - \tau^0)^{\alpha}) \text{ for any } 0 < \tau_1 < \tau_2 \leq T.$$

Similarly for the discretised case, we define $\frac{1}{\sqrt{T^2 - \tau_1^2}} \sum_{\tau \leq t \leq \tau_2} R(t, \tau)Z_{ult} = O_p(\log \delta^* T)$ or $O_p((\tau - \tau^0)^{\alpha})$. Furthermore, it follows from Proposition 3.2-3.3 and Continuous Mapping Theorem that

$$\frac{1}{T} \mathbb{P}|Q_{(i, \tau)}| = O_p(1) \text{ and } \mathbb{P}|Q_{(i, \tau)}| = O_p(1).$$

for any $\tau_1, \tau_2 \in (0, \tau^0, \hat{\tau}, T)$ such that $\tau_1 < \tau^* < \tau_2$. Then, applying the Cauchy-Schwarz’s inequality to $A.5$ and $A.9$, together with above asymptotic results, we have that $A.3$ and $A.4$ are both $O_p(1)$. Hence, $A.1$ is dominated by $A.2$, which is positive, and thus gives a contradiction. Therefore, $\hat{\delta} - \delta^* \xrightarrow{T\rightarrow\infty} 0$. 
\qed
Proof of Proposition 4.2. Write \( \phi := \frac{1}{\sqrt{r}} \) and \( V_\eta := \{ \tau : |\tau - \theta^0| \leq \eta T \} \). It follows from Proposition 4.1 that for each \( \eta > 0 \), \( P(\hat{\tau} \in V_\eta) \to 1 \). Therefore, we only need to investigate the sum of squared error \( SSE(\hat{\tau}) \) for those \( \hat{\tau} \in V_\eta \). For \( C > 0 \), define the set \( V_C = \{ \tau : C < |\tau - \theta^0| < \eta T \} \) and let \( \hat{\tau} \) be the estimated change point with the minimum taken over the set \( V_C \). Then, it suffices to show that the order of these three terms, or one of the three terms is larger than all of the remaining terms in (A.1), and that leads to a contradiction since the term (A.1) \( \leq 0 \) with probability 1.

First notice that (A.2) is \( O_p(1) \) instead of \( o_p(1) \). Hence, it is difficult to compare it with (A.1) directly. In this case, we need to factorise the term (A.1). We observe that

\[
\sum_{t \in [0, T]} (Z_t(\theta^1) - \hat{\theta}^1))^2 = (a1) + (a2) + (a3),
\]

where

\[
(a1) = (\theta^{(1)} - \theta^{(2)})'Q_{(r, r)}^{-1} \sum_{t \in [0, r]} Z_t' Z_t Q_{(0, r)}^{-1} Q_{r, r} (\theta^{(1)} - \theta^{(2)}),
\]

\[
(a2) = R_{(0, 0), r} \sigma^2 Q_{(0, r)}^{-1} \times \sum_{t \in [0, r]} Z_t' Z_t Q_{(0, r)}^{-1} R_{(0, r)},
\]

\[
(a3) = 2\sigma(\theta^{(1)} - \theta^{(2)})'Q_{(r, r)}^{-1} \sum_{t \in [0, r]} Z_t' Z_t Q_{(0, r)}^{-1} R_{(0, r)}.
\]

Similarly,

\[
\sum_{t \in (\hat{\tau}, T]} (Z_t(\theta^2) - \hat{\theta}^2))^2 = (a4) + (a5) + (a6),
\]

where

\[
(a4) = (\theta^{(1)} - \theta^{(2)})'Q_{(r, r)}^{-1} \sum_{t \in [r, T]} Z_t' Z_t Q_{(0, r)}^{-1} Q_{r, r} (\theta^{(1)} - \theta^{(2)}),
\]

\[
(a5) = R_{(0, 0), r} \sigma^2 Q_{(0, r)}^{-1} \times \sum_{t \in [r, T]} Z_t' Z_t Q_{(0, r)}^{-1} R_{(0, r)},
\]

\[
(a6) = 2\sigma(\theta^{(1)} - \theta^{(2)})'Q_{(0, r)}^{-1} \sum_{t \in [r, T]} Z_t' Z_t Q_{(0, r)}^{-1} R_{(0, r)}.
\]

and

\[
\sum_{t \in (\hat{\tau}, T]} (Z_t(\theta^2) - Z_t \hat{\theta}^2)' (Z_t \hat{\theta}^2 - Z_t \hat{\theta}^2) = \sigma^2 R_{(r, r)} Q_{(r, T)}^{-1} \sum_{t \in [r, T]} Z_t' Z_t Q_{(r, T)}^{-1} R_{(r, T)} = (a7).
\]

One could see that \( \phi(a1), \phi(a4) \) and \( \phi(a6) \) are all of order \( O_p(1) \). Additionally, by Theorem A.1 in Tobing and McGlachrist (1992), we have that for large \( T \),

\[
Q_{(0, r)}^{-1} = O_{(0, r)}^{-1} + O_p \left( \frac{T - r^0}{T^2} \right) \quad \text{(A.13)}
\]
Therefore,
\[
R'(0,\tau)Q^{-1}(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) R(0,\tau) - R'(0,\tau)Q^{-1}(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) R(0,\tau) \tag{A.14}
\]
\[=(R(0,\tau) + R(\tau,\tau)) \left( Q^{-1}(0,\tau) + O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) \right) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) R(0,\tau),
\]
\[\times (R(0,\tau) + R(\tau,\tau)) - R(0,\tau)Q^{-1}(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) R(0,\tau),
\]
\[O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z R(0,\tau) + O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z R(0,\tau),
\]
\[+ 2R(0,\tau)Q^{-1}(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) R(0,\tau) + O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z R(0,\tau),
\]
\[+ O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(0,\tau) \sum_{\ell \in \{0,\tau\}} Z'_{\ell} Z R(0,\tau),
\]
\[+ O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(\tau,\tau) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z R(\tau,\tau),
\]
\[+ O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) R(\tau,\tau) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z R(\tau,\tau).
\]

Since \(\hat{T} - \theta^0 \leq \eta T\) for each \(\eta > 0\), and using the asymptotic results in the proof of Proposition \(4.1\) with small enough \(\eta\), we have \(\phi(\hat{T})^{2}(A.14) = o_{p}(1)\). Similarly,
\[
\phi(\hat{T})^{2} \left( R(\tau,\tau) Q^{-1}(\tau,\tau) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z Q^{-1}(\tau,\tau) R(\tau,\tau) - R(\tau,\tau)Q^{-1}(\tau,\tau) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z Q^{-1}(\tau,\tau) R(\tau,\tau) \right) = o_{p}(1).
\]

Consequently, \((a2) + (a4) + (A.2) = o_{p}(1)\). For \((a3)\), we have
\[
(\theta^{(1)} - \theta^{(2)})'Q(0,\tau)Q^{-1}(0,\tau) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) Q(0,\tau) (\theta^{(1)} - \theta^{(2)})
\]
\[=(\theta^{(1)} - \theta^{(2)})'Q(0,\tau) \left( Q^{-1}(0,\tau) + O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) \right) \sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z Q^{-1}(0,\tau) + O_{p}\left(\frac{\hat{T} - \theta^0}{T^2}\right) (\theta^{(1)} - \theta^{(2)}) + o_{p}(1),
\]
with \((\theta^{(1)} - \theta^{(2)})'\sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z (\theta^{(1)} - \theta^{(2)}) \geq \gamma_1\|\theta^{(1)} - \theta^{(2)}\|^2\), where \(\gamma_1\) is the minimum eigenvalue of \(\sum_{\ell \in \{\tau,\tau\}} Z'_{\ell} Z\). Under Assumption 4 with a suitable choice of \(C\), we have that for \(\hat{T} \in V_{\eta}(C)\), \(\gamma_1\) is bounded away from 0. Hence, \(\phi(a3) \geq C_2\|\theta^{(1)} - \theta^{(2)}\|^2\) for some \(C_2 > 0\). Moreover, applying \((A.1)\) to \((A.3)\), together with some factorisations, we have that \((A.1) = o_{p}(1)\). Therefore, the term \(\phi(a3)\) dominates all others and it is positive with probability 1 for large \(T\). This implies that with large probability, \((A.1) > 0\), which gives a contradiction. This indicates that with large probability \(\hat{T}\) can not be in the set \(V_{\eta}(C)\) and hence \(P(T | \hat{T} - \theta^0 \geq C) \leq \epsilon\) when \(T\) is large.

\[\square\]

**Remark 3.** As discussed in Remark \([7]\) in Section 4, in case the shift is of shrinking magnitude with shrinking speed \(v_T\), the asymptotic behavior (i) discussed in Remark \([7]\) may be verified by following the same arguments in the proof of Proposition \([4.1]\) with \(\phi = \frac{\hat{T} - \theta^0}{T^2}\), together with the fact that \(T \|\theta^{(1)} - \theta^{(2)}\|^2 = (T^{1/2}v_T^2)^2 \rightarrow \infty\) and \(\log T / T^{2r} \rightarrow 0\). On the other hand, (ii) may be verified by following similar arguments as in the proof of Proposition \([4.2]\) to investigate the set \(V_{\eta}(C, v_T) = \{\tau : C/v_T^2 < |\tau - \theta^0| < \eta T\}\) instead of \(V_{\eta}(C)\).
Appendix A.2. Proof of Proposition 4.3 and 4.4

Write $V(t) := (\varphi_1(t), \ldots, \varphi_p(t), -X_t)$ and let $\log L_1$ be the log likelihood function based on the estimated change point $\hat{\tau}$ and the associated MLE ($\hat{\theta}(1)$, $\hat{\theta}(2)$). That is, $\log L_1 = \frac{1}{\sigma^2} \left( \int_0^\tau S(\hat{\theta}(1), t, X_t)dX_t + \int_{\tau}^T S(\hat{\theta}(2), t, X_t)dX_t \right) - \frac{1}{\sigma^2} \left( \int_0^\tau S^2(\hat{\theta}(1), t, X_t)dt + \int_{\tau}^T S^2(\hat{\theta}(2), t, X_t)dt \right)$. Similarly, we let $\log L_0$ be the log likelihood function based on the exact value of change point $\tau^0$ and the associated MLE ($\hat{\theta}(1,0)$, $\hat{\theta}(2,0)$). Then, the proof of Propositions 4.3 and 4.4 rely on the behaviour of $\phi(\log L_1 - \log L_0)$. (A.15)

Now, without loss of generality, suppose first that $\hat{\tau} > \tau^0$ and divide the time period $[0, T]$ into three sub-intervals: $[0, \tau^0]$, $(\tau^0, \hat{\tau}]$ and $(\hat{\tau}, T]$. Using relation (2.11), along with some algebraic manipulation, we have

$$A.15 = \frac{1}{2\sigma^2} \left( \int_0^{\tau^0} (V(t)\hat{\theta}(1))^2 dt + \int_{\tau^0}^{\tau} (V(t)\hat{\theta}(1))^2 dt + \int_\tau^T (V(t)\hat{\theta}(2))^2 dt \right)$$
$$- \frac{1}{2\sigma^2} \left( \int_0^{\tau^0} (V(t)\hat{\theta}(1,0))^2 dt + \int_{\tau^0}^{\tau} (V(t)\hat{\theta}(2,0))^2 dt + \int_\tau^T (V(t)\hat{\theta}(2,0))^2 dt \right)$$
$$+ \frac{1}{\sigma} \left( \int_0^{\tau^0} (V(t)\hat{\theta}(1))dW_t + \int_{\tau^0}^{\tau} (V(t)\hat{\theta}(1))dW_t + \int_\tau^T (V(t)\hat{\theta}(2))dW_t \right)$$
$$- \frac{1}{\sigma} \left( \int_0^{\tau^0} (V(t)\hat{\theta}(1,0))dW_t + \int_{\tau^0}^{\tau} (V(t)\hat{\theta}(2,0))dW_t + \int_\tau^T (V(t)\hat{\theta}(2,0))dW_t \right).$$

We plug in the expressions of the MLEs, and after some algebraic computations, we get

$$A.15 = \frac{\phi}{\sigma} \left( 2(\theta(1) - \theta(2))'R_{(\theta,1)} - 2(\theta(1) - \theta(2))'Q_{(\theta,1)}Q_{(0,1)}(\theta(1)R_{(0,1)}) \right)$$
$$+ \frac{3\phi}{2} \left( R_{(\theta,1)}Q_{(0,1)}Q_{(0,\theta,1)}^\dagger - R_{(\theta,0,1)}Q_{(0,\theta,1)}^\daggerR_{(0,\theta,1)} + R_{(\theta,1)}Q_{(\theta,1)}R_{(0,\theta,1)} \right)$$
$$\leq \frac{3\phi}{2} \left( R_{(\theta,1)}Q_{(0,\theta,1)}Q_{(0,\theta,1)}^\dagger - \theta(1) \right) \right)$$
$$- \frac{\phi}{2\sigma^2} (\theta(1) - \theta(2))'Q_{(\theta,1)}Q_{(0,\theta,1)}(\theta(1) - \theta(2)).$$

The remaining parts of the proofs for Propositions 4.3 and 4.4 depend on investigating the asymptotic behaviours of $A.16 - A.19$.

Proof of Proposition 4.3. Let $\phi = \frac{1}{\tau^0}$. Note that log $L_1$ is taken to be the maximum of the log likelihood function from all possible choices of $\tau \in [0, T]$ whilst log $L_0$ is based on one particular change point $\tau^0 \in [0, T]$. It follows from the definition of MLE that $A.15 \geq 0$ with probability 1. However, if the rate of change point $\tau^0$ is not consistently estimated by $\hat{\tau}$, then with positive probability, we have $\hat{\tau} - \tau^0 = (\hat{\delta} - \delta)T > L_{\tau^0}$, where $L_{\tau^0}$ is defined in Assumption 4. In this case, under Assumptions 3 and 5, the minimum eigenvalue of $D' = \frac{1}{2(\theta(1) - \theta(2))'Q_{(\theta,1)}Q_{(\theta,1)}^\dagger(\theta(1) - \theta(2))}$ is bounded away from 0. Denoting this minimum eigenvalue by $\gamma_2$, we have

$$\frac{\phi}{2\sigma^2} (\theta(1) - \theta(2))'Q_{(\theta,1)}Q_{(\theta,1)}^\dagger(\theta(1) - \theta(2)) = \frac{(\hat{\delta} - \delta)\gamma_2}{4\sigma^2} (\theta(1) - \theta(2))'(\theta(1) - \theta(2)) \geq \frac{(\hat{\delta} - \delta}\gamma_2}{4\sigma^2} ||(\theta(1) - \theta(2)||^2. \hspace{1cm} \text{(A.20)}$$

So, $A.19 \leq -C_3||(\theta(1) - \theta(2)||^2$ with $C_3 = \frac{(\hat{\delta} - \delta)\gamma_2}{4\sigma^2} > 0$. Using (A.11) and (A.12), together with Cauchy-Schwarz’s inequality, along with some algebraic computations, we find that $A.16 - A.18$ are all of order $o_p(1)$. Hence, $A.15$ is dominated by $A.19$, which is negative. This means that $A.15 < 0$ with positive probability, which is a contradiction. Therefore, for large $T$ and $\forall \epsilon > 0$, $\hat{\delta} - \delta < \epsilon$. This implies that $\hat{\delta} - \delta \evaluated{T \to \infty} 0$, which completes the proof.

Proof of Proposition 4.4. Write $\phi := \frac{1}{T - \tau^0}$ and $V_\eta := \{ \tau : |\tau - \tau^0| \leq \eta T \}$. Then, it follows from Proposition 4.3 that for each $\eta > 0$, $P(\hat{\tau} \in V_\eta) \evaluated{T \to \infty} 1$. Therefore, we only need to investigate the asymptotic behaviour of $A.16 - A.19$ for those $\hat{\tau} \in V_\eta$. For $C > 0$, define the set $V_\eta(C) = \{ \tau : C < |\tau - \tau^0| < \eta T \}$ and let $\hat{\tau}$ be the estimated change point with the minimum
taken over the set $V_0(C)$. Then, it suffices to show that for some $C > 0$, such that for any $\hat{\tau} \in V_0(C)$, (A.1) is suitable with positive probability, and this leads to a contradiction since the term $t_{\hat{\tau}}(A.1) \leq 0$ with probability 1. This would imply that for some $C > 0$ and any $0 < \eta < 1$, the global optimisation cannot be achieved on the set $V_0(C)$. Thus with large probability, $|\hat{\tau} - \tau^0| \leq C$.

First note that under Assumption 4, with a suitable $C$, it follows from (A.20) that $t_{\hat{\tau}}(A.19) \leq -C_3\|t^{(1)} - t^{(2)}\|^2$ for some $C_3 > 0$.

Next, for (A.16), by (A.11) and the Cauchy-Schwarz’s inequality, we have

$$\frac{2(\theta^{(1)} - \theta^{(2)}) R(\tau, T)}{\sigma(\hat{\tau} - \tau^0)} \leq \frac{2}{\sigma \sqrt{\hat{\tau} - \tau^0}} \left\| \theta^{(1)} - \theta^{(2)} \right\| \left\| R(\tau, T) \right\| = (\hat{\tau} - \tau^0)^{1/2} O_p(1),$$

where $0 < a^* < 1/2$, and

$$\frac{2(\theta^{(1)} - \theta^{(2)}) Q(\tau, T) R(0, \tau)}{\sigma(\hat{\tau} - \tau^0)} \leq \frac{2}{\sigma \sqrt{T}} \left\| \theta^{(1)} - \theta^{(2)} \right\| \left\| Q(\tau, T) R(0, \tau) \right\| \left\| T Q^{-1}(\tau, T) \right\| \left(\frac{1}{\sqrt{T}} \right) R(0, \tau) = O_p(1).$$

For (A.18), applying again Theorem A.1 in Tobing and McGlichirist (1992), we have that for large $T$,

$$Q_{\tau, T}^{-1} = Q_{\tau, T}^{-1} + O_p \left(\frac{\hat{\tau} - \tau^0}{T^2}\right).$$

Together with (A.13), we obtain

$$R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} - R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} = R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} - 2 R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} + O_p \left(\frac{\hat{\tau} - \tau^0}{T^2}\right) R_{\tau, T}^{-1} R_{\tau, T}$$

and

$$R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} = R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} - 2 R_{\tau, T}^{-1} Q_{\tau, T}^{-1} R_{\tau, T} + O_p \left(\frac{\hat{\tau} - \tau^0}{T^2}\right) R_{\tau, T}^{-1} R_{\tau, T}.$$

From (A.11), (A.12), together with Cauchy-Schwarz’s inequality, we have (A.18) is a suitable $C$, we obtain (A.19) + (A.16) < 0, which implies that (A.15) < 0 and this gives a contradiction. Therefore, with large probability, $\hat{\tau}$ can not be in the set $V_0(C)$ and hence $P(T|\hat{\tau} - \hat{\tau}^0 | \geq C) \leq \epsilon$ when $T$ is large.

**Appendix B. Proof of Proposition $5.1$.**

This proof can be completed by comparing $IC(m = 0)$ and $IC(m = 1)$ under $H_0$ and $H_1$, respectively. Moreover, note that $log(T/\Delta_0) = log T - log(\Delta_0)$ and $log T$ is just a special case of $log(T/\Delta_0)$ with $\Delta_0 = 1$. Hence, in the succeeding proof, we only prove the case $q(T) = log(T/\Delta_0)$ with $\Delta_0$ a fixed constant.

**Proof.** Under $H_0$, $m^0 = 0$ and $\theta^{(1)} = \theta^{(2)}$. In this case, for $IC(m = 0)$, it follows from (2.1) that

$$IC(m = 0) = -2 \left(\frac{1}{\sigma^2} \int_0^T S(\hat{\theta}^{(1)}, t, X_i) dX_i - \frac{1}{2\sigma^2} \int_0^T S(\hat{\theta}^{(1)}, t, X_i)^2 dt \right) + h(p) log(T/\Delta_0) \leq -\frac{1}{2\sigma^2} \theta^{(1)} Q_{0,T} \theta^{(1)} - \frac{4}{\sigma} \theta^{(1)} R_{0,T} - 3 R_{0,T} Q_{0,T}^{-1} R_{0,T}$$

Assume further that we get $\hat{\tau}$ from (4.6) when $m$ is set to 1 (note that in this case $\theta^{(2)}$ is still equal to $\theta^{(1)}$). Then,

$$IC(m = 1) = -\frac{1}{2\sigma^2} \theta^{(1)} Q_{0,T} \theta^{(1)} - \frac{4}{\sigma} \theta^{(1)} R_{0,T} - 3 R_{0,T} Q_{0,T}^{-1} R_{0,T}$$

so that

$$IC(m = 1) - IC(m = 0) = 3 R_{0,T} Q_{0,T}^{-1} R_{0,T} - 3 R_{0,T} Q_{0,T}^{-1} R_{0,T} = 3 R_{0,T} Q_{0,T}^{-1} R_{0,T} + h(p)(log T - log(\Delta_0)).$$

**B.1**
Moreover, by (A.11) and (A.12), together with the Cauchy-Schwarz’ inequality,
\[ R'_{(t,T)} Q_{(t,T)}^{-1} R_{(0,T)} \leq \frac{1}{\sqrt{T}} R_{(0,T)} \| T Q_{(t,T)}^{-1} \| = O_p(\log^{2\nu - 1} T), \]
where \(0 < \alpha^* < 1/2\). Similarly, \(R'_{(t,T)} Q_{(t,T)}^{-1} R_{(0,T)}\) and \(R'_{(0,T)} Q_{(t,T)}^{-1} R_{(0,T)}\) are also of order \(O_p(\log^{2\nu - 1} T)\). Therefore, for large \(T\) and fixed \(\Delta, \varepsilon\), (B.1) is dominated by \(h(p) \log T\), which is positive. This implies that under \(H_0\), the probability of \(IC(m = 0) > IC(m = 1)\) tends to 0 as \(T\) tends to \(\infty\).

Under \(H_1\), let \(r^0\) be the exact value of the change point and \(\hat{r}\) be the estimator of \(r^0\) obtained from (4.6). Without loss of generality, we assume that \(\hat{r} > r^0\). So,
\[
IC(m = 0) = -\frac{1}{\sigma^2} \theta^2 \theta'^2 Q_{(r^0,r^0)}(\theta^2) - \frac{1}{\sigma^2} (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 4 \sigma (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2),
\]
and
\[
IC(m = 1) = -\frac{1}{\sigma^2} \theta^2 \theta'^2 Q_{(r^0,r^0)}(\theta^2) - \frac{1}{\sigma^2} (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 4 \sigma (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - 2 \theta (p)(\log T - \log(\Delta)).
\]

Therefore,
\[
IC(m = 1) - IC(m = 0) = -\frac{1}{\sigma^2} (\theta^1 - \theta^2)'^3 Q_{(r^0,r^0)}(\theta^2) Q_{(r^0,r^0)}^{-1} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 3 R'_{(r^0,r^0)} Q_{(r^0,r^0)}^{-1} R_{(r^0,r^0)} - 4 \sigma (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - 2 \theta (p)(\log T - \log(\Delta)).
\]

Multiplying both sides of the above identity by \(\frac{1}{T}\), and using (A.11), (A.12) and the Cauchy-Schwarz’ inequality, we have
\[
\frac{1}{T} (IC(m = 1) - IC(m = 0)) = \frac{1}{\sigma^2} \theta^2 \theta'^2 Q_{(r^0,r^0)}(\theta^2) - \frac{1}{\sigma^2} (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) - (1 - s^2) - 2 \theta (p)(\log T - \log(\Delta)).
\]

Note that the second term in (B.2) is equal to
\[
\frac{1}{\sigma^2} \theta^2 \theta'^2 Q_{(r^0,r^0)}(\theta^2) - \frac{1}{\sigma^2} (\theta^1 - \theta^2)' Q_{(r^0,r^0)} Q_{(r^0,r^0)}(\theta^1 - \theta^2) = o_p(1).
\]

Using the similar argument as in the proof of Proposition 4.3, we have that under Assumption 4.4 that the second term is less than \(-C_4\|\theta^1 - \theta^2\|^2\) for some \(C_4 > 0\). It also follows from Proposition 4.4 that \(\| Q_{(r^0,r^0)} \| = \frac{1}{T} \| Q_{(r^0,r^0)} \| = o_p(1)\) for large \(T\). Thus, by (A.12), together with the Cauchy-Schwarz’ inequality we have
\[
\frac{1}{\sigma^2} (\theta^1 - \theta^2)' Q_{(r^0,r^0)}(\theta^1 - \theta^2) = o_p(1).
\]

This tells us that (B.2) is dominated by the first term for large \(T\) and it is negative. Therefore \(IC(m = 0) > IC(m = 1)\) with probability 1.

\[\square\]
