NON-EXPLOSION CRITERIA FOR RELATIVISTIC DIFFUSIONS

ISMAËL BAILLEUL AND JACQUES FRANCHI

Abstract. General Lorentz covariant operators, associated to so-called $\Theta$ (or $\Xi$)-relativistic diffusions, and making sense in any Lorentzian manifold, were introduced by Franchi and Le Jan in [FLJ07], [FLJ10]. Only a few examples have been studied. We provide in this work non-explosion criteria for these diffusions, which can be used in generic cases.

1. Introduction

It is well known that the metric completeness of a Riemannian manifold does not prevent Brownian motion from exploding within a finite time with positive probability. The situation is now well-understood, in particular thanks to the works of Yau, [Yau78], Grigor’yan [Gri86], Takeda [Tak89], [Tak91], and very recently Hsu and Qin [HQ10], to cite but a few names. Different lines of approach have been used. Yau and Grigor’yan treated the analytic counterpart of the completeness problem and investigated the well-posedness of the parabolic Cauchy problem, the former using local information on the geometry under the form of curvature bounds, the latter using a global information under the form of an upper bound

for the volume of large balls. Takeda used a purely probabilistic method due to Lyons and Zheng in [LZ88], based on reversibility. This approach was recently improved by Hsu and Qin in [HQ10]. Hsu used stochastic analysis in [Hsu02], Theorem 3.5.1, to control the radial process, by estimating the Laplacian of the distance function to a fixed point in terms of curvature bounds. All these results are tied down to the metric framework provided by a complete Riemannian manifold.

A natural analogue of Brownian motion in a Lorentzian setting was first introduced by Dudley in [Dud66] in the special relativistic case, and extended to the general relativistic framework by Franchi and Le Jan in [FLJ07]. It belongs to a larger class of relativistic processes introduced in [Bai10] and [FLJ10], defined in purely geometric terms, and collectively referred to as relativistic diffusions. Their trajectories represent the random motion in spacetime of a small massive particle, and make sense only in the unit tangent bundle or in the orthonormal frame bundle. Only a few examples have been studied in detail up to now: in Minkowski spacetime (the framework of special relativity) [Dud66], [Bai08], [BR08], in Robertson-Walker spacetimes (models of universe with a big-bang) [Ang09], Gödel spacetime (a causally paradoxical universe) [Fra09], and Schwarzschild spacetime (a model for an isolated star or a black hole) [FLJ07].

Apart from the works [Bai10] and [FLJ10], no general study of these intrinsic random processes was done. As a first step towards a better understanding of these processes and their interplay with the geometry of the ambient spacetime, we provide in this work some non-explosion criteria for some generic classes of Lorentz manifolds. In addition to being a natural question, the completeness issue is strongly related to important questions in general relativity. Indeed, dating back to Penrose and Hawking’s incompleteness theorems, the appearance of singularities in Einstein’s theory of gravitation has been recognized as unavoidable under quite natural assumptions. Although there is no agreement on what should be called a singularity of a spacetime, the existence of incomplete geodesics has been widely used as an indicator of such a singular feature. In so far as the random dynamics considered in this work (§2.2) can be seen as intrinsic perturbations of the geodesic flow, their completeness/incompleteness is a distinguishing feature of a spacetime. We refer the reader to [Bai11] for a first approach of stochastic incompleteness.

The paths of the random processes we shall consider are (almost-)all $C^1$ paths parametrized by their (proper time) arc length. What could possibly make them explode? In a complete Riemannian manifold, any such path would have to be at time $s$ in a closed ball of radius $s$ with centre its starting point, so it cannot explode. There are two problems with the Lorentzian setting: a Lorentzian manifold has no metric or finite distance function associated with its structure, and the set of unit tangent vectors at any point is non-compact. As a result, even in Minkowski spacetime, one can construct exploding paths with finite (proper time) arc length.

To start our investigations, we shall take advantage in Section 3 of the bundle structure of the state space of the process, to exhibit a one-dimensional sub-process whose control is possible in the class of globally hyperbolic spacetimes. This structure allows indeed to define some Lyapounov function and leads to a non-explosion criterion by using a simple and well-known observation due to Khasminsky.

With a metric missing, the completeness notion used in a crucial way in the Riemannian setting becomes unavailable. Busemann, Hawking and Ellis, Schmidt, Beem and Ehrlich, proposed different notions in replacement. Schmidt’s idea is to give a Riemannian structure
to the orthonormal frame bundle. We consider Schmidt $b$-completeness notion in Section 4, showing how it leads to a stochastic completeness result for some of the relativistic diffusions.

This result can be significantly improved by adapting Takeda’s strategy [Tak91], as improved by Hsu and Qin [HQ10], to the Lorentzian setting. This is however far from being straightforward, since we are working in a non-symmetric, non-elliptic setting, where the main ingredients of Takeda’s method (use of symmetry and reflected Brownian motion on the boundary of large Riemannian balls) have no obvious Lorentzian counterpart. To overcome this difficulty, we use in Section 5 a sub-Riemannian structure well-adapted to our setting, and which will somehow play for us the role of the non-existing Lorentzian distance.

Aknowledgements. We thank E. Trélat for his guidance in the realm of control theory, and A. Oancea and P. Pansu for their help in proving Lemma 15.

2. RELATIVISTIC DIFFUSIONS

2.1. Basic geometrical setting. Recall Minkowski space is the product $\mathbb{R}^{1,d} \equiv \mathbb{R} \times \mathbb{R}^d$ equipped with the metric

$$g_M(q, q) := t^2 - |x_1|^2 - \cdots - |x_d|^2,$$

for any $q = (t, x) \in \mathbb{R}^{1,d}$,

where $(t, x_1, \ldots, x_d)$ denote the coordinates of $q$ in the canonical basis $\{e_0, e_1, \ldots, e_d\}$ of $\mathbb{R}^{1,d}$.

Let $(\mathbb{M}, g)$ be a smooth $(1 + d)$-dimensional Lorentzian manifold (with $d \geq 2$), which we shall always suppose to be oriented and time-oriented. (We refer the reader to the books of Hawking-Ellis [HE73] and O’Neill [O’N83] for the basics on Lorentzian geometry.) Given any point $m \in \mathbb{M}$, it is usual to consider an orthonormal basis $\{e_0, \ldots, e_d\}$ of the tangent space $T_m\mathbb{M}$ as an isometry $e$ from $(\mathbb{R}^{1,d}, g_M)$ to $(T_m\mathbb{M}, g_m)$; so, strictly speaking, $e_i = e(e_i)$. The orthonormal frame bundle of $\mathbb{M}$ is just the collection

$$\mathbb{OM} = \{ \Phi = (m, e) \mid m \in \mathbb{M}, \ e \text{ an orthonormal basis of } (T_m\mathbb{M}, g_m) \}.$$

We shall write $\mathbb{OU} = \{ \Phi = (m, e) \mid m \in \mathcal{U}, \ e \text{ an orthonormal basis of } T_m\mathbb{M} \}$ for any subset $\mathcal{U}$ of $\mathbb{M}$. For a small enough $\mathcal{U}$ and a chart $x : \mathcal{U} \to \mathbb{R}^{1+d}$ on it, we shall write $e_j = e^i_j \partial_{x^i}$ for each vector $e_j$ of a frame $e$; this decomposition provides local coordinates $(x^i, e^j_x)$ on $\mathbb{OU}$.

Each fibre $\mathbb{Om}\mathbb{M}$ is modelled on the non-compact orthogonal group $O(1,d)$, which has four connected components. We shall be interested in dynamics leaving these components globally fixed. We choose to consider only one of them, specified by the requirement that $e_0$ should be future-oriented and that the orientation of $e$ should be direct. We shall still denote the resulting frame bundle by $\mathbb{OM}$, as there will be no risk of confusion. The Lorentz-Möbius group $SO_0(1,d)$, i.e. the connected component of the unit in $O(1,d)$, acts properly on $\mathbb{OM}$. This natural action induces the canonical vertical vector fields $(V_{ij})_{0 \leq i < j \leq d}$. The subgroup of elements in $SO_0(1,d)$ that fix $e_0$ can be identified with the rotation group $SO(d)$, and generates the vector fields $(V_{ij})_{1 \leq i < j \leq d}$. To shorten notations we shall write $V_j$ for $V_{0j}$; it generates boosts, that is hyperbolic rotations in each fibre, and reads in the above local coordinates:

$$V_j = e^k_j \partial_{e^i_0} + e^k_0 \partial_{e^i_j}.$$ 

Throughout this work, $\mathbb{T}\mathbb{M}$ and $\mathbb{OM}$ will be endowed with the Levi-Civita connection, inherited from the Lorentzian pseudo-metric $g$. Last, we denote by $H_0$ the vector field
generating the geodesic flow on $\mathcal{O}M$. Denoting by $\Gamma^k_{ij}$ the Christoffel coefficients, we have in the above local chart on $\mathcal{O}M$:

$$H_0 = e_i^k \partial_{x^k} - e_i^k e_j^\ell \Gamma^k_{ij} \frac{\partial}{\partial e_j^\ell}.$$  

We shall denote by $T^1\mathcal{M}$ the future-oriented unit tangent bundle over $\mathcal{M}$, with generic element $(m, \dot{m})$. In Minkowski spacetime $\mathbb{R}^{1,d}$, it is the product of $\mathbb{R}^{1,d}$ by the hyperboloid $\mathbb{H} = \{ q = (t, x) \in \mathbb{R}^{1,d} : g(q, q) = 1, \ t > 0 \}$. The bundle $T^1\mathcal{M}$ is locally modelled on that product. (Consult [HE73] or [ONS3] for some background.) Denote by $\pi_1$ the projection $(m, e) \mapsto (m, e_0 \equiv \dot{m})$ from $\mathcal{O}M$ to $T^1\mathcal{M}$, and by $\pi_0$ the canonical projection $\mathcal{O}M \to \mathcal{M}$.

2.2. Relativistic random dynamics. Relativistic diffusions model the random motion in spacetime of a small massive particle parametrized by its proper time, providing random timelike paths; so, properly speaking, their mathematical counterpart are random trajectories $(m_s, \dot{m}_s)$ in the future unit bundle $T^1\mathcal{M}$ subject to the condition $\frac{d}{ds}m_s = \dot{m}_s$. Yet it happens to be more convenient to define random dynamics in the orthonormal frame bundle $\mathcal{O}M$ as it bears more structure than $T^1\mathcal{M}$; these diffusions on $\mathcal{O}M$ are constructed so as to have a projection on $T^1\mathcal{M}$ which is itself a diffusion. Such a construction is reminiscent of Malliavin-Eells-Elworthy’s construction of Brownian motion on a Riemannian manifold as the projection of a diffusion on the orthonormal frame bundle.

2.2.1. Dynamics in $\mathcal{O}M$. Given any smooth non-negative function $\Theta : T^1\mathcal{M} \to \mathbb{R}_+$, identified to a $SO(d)$-invariant function on $\mathcal{O}M$ by setting $\Theta(\Phi) := \Theta(\pi_1(\Phi))$, consider the following Stratonovich equation on $\mathcal{O}M$:

$$\circ d\Phi_s = H_0(\Phi_s) \, ds + \frac{1}{2} \sum_{1 \leq j \leq d} V_j(\Phi_s) V_j(\Phi_s) \, ds + \sqrt{\Theta(\Phi_s)} \sum_{1 \leq j \leq d} V_j(\Phi_s) \circ dw^j_s,$$  

where $w$ is a $d$-dimensional Brownian motion and where we understand a vector field as a first order differential operator. This equation has a unique maximal strong solution, defined up to its explosion time $\zeta$.

It is clear on this equation that the $(e_1, \ldots, e_d)$-part of $\Phi_s$ is irrelevant in defining the dynamics of $(m_s, e_0(s))$ since $\Theta(\Phi)$ depends only on $\pi_1(\Phi)$; this is the reason why this diffusion on $\mathcal{O}M$ projects down in $T^1\mathcal{M}$ onto a diffusion. Consult [FLJ07], Theorem 1, or [FLJ10], Theorem 3.2.1, or §3.2 of [Bai10], for the details. The diffusion in $\mathcal{O}M$ has generator

$$\mathcal{G}_\Theta = H_0 + \frac{1}{2} \sum_{1 \leq j \leq d} V_j(\Theta V_j).$$

We shall generically call these relativistic dynamics $\Theta$-diffusions (the $\Xi$-diffusions of [FLJ10]). These diffusions are covariant, in the sense that any isometry of $(\mathcal{M}, g)$ maps a $\Theta$-diffusion to a $\Theta$-diffusion (with the same $\Theta$; the law is preserved, up to the starting point), and admit the Liouville measure as an invariant measure. The $\pi_0$-projections (on the base manifold $\mathcal{M}$) of their trajectories are almost-surely $C^1$ paths. A $\Theta$-diffusion $(\Phi_s)_{0 \leq s < \zeta}$ solving Equation (2.3) is parametrized by proper time $s \geq 0$. The particular case $\Theta = 0$ gives back the deterministic geodesic flow, and the case of a non-null constant $\Theta$ gives back the relativistic diffusion as defined first in [FLJ07], which we shall call the basic relativistic diffusion. It is described in simple terms in Minkowski spacetime. Although the metric $g_M$ is non-definite positive, its restriction to any tangent space of the half sphere $\mathbb{H}$ of unit tangent vectors is definite negative; this turns $\mathbb{H}$ into a Riemannian manifold with constant
negative curvature. Dudley’s diffusion \((m_s, e_s) = (m_s, (e_0(s), \ldots, e_d(s)))\), which is the basic relativistic diffusion in Minkowski spacetime, corresponds to taking \(m_s = m_0 + \int_0^s e_0(r) \, dr\), and for the velocity \(e_0(r)\) a Brownian motion on \(\mathbb{H}\). The remainder \(e_1(r), \ldots, e_d(r)\) of the basis is obtained by parallel transport of \(e_1(0), \ldots, e_d(0)\) along the Brownian path \((e_0(u))_{0 \leq u \leq r}\).

The following elementary lemma proved in [Bai11], §2.2, gives an intuitive picture of the \(\Theta\)-diffusions, for \(\Theta\) depending only on \(m \in \mathbb{M}\).

**Lemma 1.** Let \(\gamma : [0, T] \to \mathbb{M}\) be a \(C^2\) timelike path parametrized by its proper time, and \(\Gamma_0 \in \mathcal{OM}\) such that \(\pi_1(\Gamma_0) = (\gamma(0), \gamma(0)) \in T^1 \mathbb{M}\). Then there exists a unique \(C^2\) path \((\Psi_s)_{0 \leq s \leq T}\) in \(\mathcal{OM}\), and some unique \(C^1\) real-valued controls \(h^1, \ldots, h^d\) defined on \([0, T]\), such that \(\Psi_0 = \Gamma_0\), \(\pi_1(\Psi_s) = (\gamma(s), \dot{\gamma}(s))\) and

\[
\dot{\Psi}_s = H_0(\Psi_s) + \sum_{j=1}^d V_j(\Psi_s) h^j(s).
\]

So the \(\Theta\)-diffusion is obtained by replacing the deterministic controls of a typical \(C^2\) timelike path by Brownian controls with position dependent variance \(\Theta(m_s)\).

On a manifold with non-positive scalar curvature \(R\), taking \(\Theta(\Phi) = -\varrho^2 R\) (for a non-null constant \(\varrho\)), one gets a dynamics which can be truly random only in non-empty parts of spacetime; it was called \(R\)-diffusion in [FLJ10]. Denote by \(\mathbf{T}\) the energy-momentum tensor of the spacetime. Taking \(\Theta(\Phi) = \varrho^2 \mathbf{T}(e_0, e_0)\), we get what was named the energy diffusion in [FLJ10]. See [Bai11] for more general models of diffusions.

### 2.2.2. Dynamics in \(T^1 \mathbb{M}\).

Denote by \(\nabla^v\) the gradient on \(T^1 \mathbb{M}\), identified with the hyperbolic space \(\mathbb{H}^d\) by means of the metric \(g_m\), and by \(\mathcal{L}_0\) the vector field generating the geodesic flow on \(T^1 \mathbb{M}\). Note that \(T\pi_1(H_0) = \mathcal{L}_0\) and \(T\pi_1(V_j) = : \nabla^v = e^k_j \partial_{\dot{m}^k}\) (with Einstein summation convention). The projection on \(T^1 \mathbb{M}\) of the \(\mathcal{OM}\)-valued diffusion has the following \(SO(d)\)-invariant generator:

\[
\mathcal{L}_\Theta = \mathcal{L}_0 + \frac{1}{2} \nabla^v(\Theta \nabla^v).
\]

For a constant \(\Theta\) the operator \(\mathcal{L}_\Theta\) has the following expression in the local coordinates introduced in §2.1

\[
\mathcal{L}_0 + \frac{\Theta}{2} \Delta^v = \dot{\dot{m}}^k \frac{\partial}{\partial \dot{m}^k} + \left( \frac{d}{2} \Theta \dot{\dot{m}}^k - \dot{m}^i \dot{m}^j \Gamma^k_{ij}(m) \right) \frac{\partial}{\partial \dot{m}^k} + \frac{\Theta}{2} \left( \dot{m}^k \dot{\dot{m}}^\ell - g^{kl}(m) \right) \frac{\partial^2}{\partial \dot{m}^k \partial \dot{m}^\ell},
\]

where \(\Delta^v\) denotes the vertical Laplacian. We have for a generic \(\Theta\):

\[
(2.5) \quad \mathcal{L}_\Theta = \mathcal{L}_0 + \frac{\Theta}{2} \Delta^v + \frac{1}{2} \left( \dot{m}^k \dot{\dot{m}}^\ell - g^{kl}(m) \right) \frac{\partial \Theta}{\partial \dot{m}^k} \frac{\partial}{\partial \dot{m}^\ell}.
\]

The purpose of this work is to provide some conditions under which the \(\Theta\)-diffusions have almost-surely an infinite lifetime \(\zeta\). In so far as we are mainly interested in the \(T^1 \mathbb{M}\)-valued \(\Theta\)-diffusions as models of physical phenomena, while we shall mainly be working with \(\mathcal{OM}\)-valued diffusions, it is reassuring to have the following fact, which essentially means that the possible explosion of \((\Phi_s)_{0 \leq s < \zeta}\) is never due to its \((e_1, \ldots, e_d)\)-part.

**Proposition 2.** The \(\Theta\)-diffusion on \(\mathcal{OM}\) and its \(T^1 \mathbb{M}\)-projection have the same lifetime.
**Proof** – Write $\Phi_s = \left(\{\tilde{m}_s, \tilde{e}_1(s), \ldots, \tilde{e}_d(s)\}\right) \in \Omega M$ and $\phi_s := \pi_1(\Phi_s) = (m_s, \tilde{m}_s) \in T^1\Omega M$. Using the local coordinates $(x^k, e^k_j)_{0 \leq k, \ell \leq d, 1 \leq j \leq d}$, Equation (2.3) defining the $\Theta$-diffusion reads:

$$
\begin{align*}
\dot{m}^k_s &= dM^k_s - \Gamma^k_{ij}(m_s) \tilde{m}^i_s \tilde{m}^j_s ds + \frac{d}{2} \Theta(\phi_s) \dot{m}^k_s ds + \frac{1}{2} \left(\dot{\tilde{m}}^k_s \dot{\tilde{m}}^j_s - g^{k\ell}(m_s)\right) \frac{\partial}{\partial \tilde{m}^j_s}(\phi_s) ds, \\
\dot{e}^j_s &= \sqrt{\Theta(\phi_s)} \dot{m}^j_s \omega^j ds - \Gamma^j_{ik}(m_s) \dot{e}^i_s(s) \dot{m}^j_s ds + \frac{1}{2} \Theta(\phi_s) e^j_s(s) ds + \frac{1}{2} V_j \Theta(\phi_s) \dot{m}^k_s ds,
\end{align*}
$$

with the martingale term $dM^k_s := \sqrt{\Theta(\phi_s)} \dot{e}^j_s(s) \omega^j ds$. (See Section 3.2 of [FLJ10] for the computation of the Itô correction.) Setting $e_0 = \tilde{m}$ and $\eta^m := \eta^m := 1_{i=n=0} - 1_{1 \leq i = m \leq d}$, and noticing that the matrix $(\eta^m e^j_k g_{kl})_{0 \leq i, j, k, \ell \leq d}$ is the inverse of the matrix $(\dot{e}_j^k)_{0 \leq i, j, k \leq d}$, it follows from the above system that we have for all $0 \leq k \leq d, 1 \leq j \leq d$:

$$
\begin{align*}
\dot{e}^j_s(s) &= \eta^m e^j_k(s) g_{kl}(m_s) dM^l_s - \Gamma^j_{ik}(m_s) \dot{e}^i_s(s) \dot{m}^j_s ds + \frac{1}{2} \Theta(\phi_s) e^j_s(s) ds + \frac{1}{2} V_j \Theta(\phi_s) \dot{m}^k_s ds \\
&= - e^j_s(s) \Gamma^j_{ik}(m_s) \dot{m}^k_s ds + \frac{1}{2} \dot{e}^j(s)(\phi_s) \Theta(\phi_s) ds + \frac{1}{2} V_j \Theta(\phi_s) \dot{m}^k_s ds \\
&- \dot{e}^j(s) \dot{m}^k_s g_{kl}(m_s) \left[\dot{\tilde{m}}^i_s \dot{\tilde{m}}^j_s \dot{\tilde{m}}^p_s - \frac{d}{2} \Theta(\phi_s) \dot{m}^k_s ds - \frac{1}{2} \left[\dot{\tilde{m}}^p_s \dot{\tilde{m}}^j_s - g^{p\ell}(m_s)\right] \frac{\partial}{\partial \tilde{m}^j_s}(\phi_s) ds\right].
\end{align*}
$$

So the matrix $(\dot{e}^j_k(s))_{0 \leq s < \zeta}$ and the frame-valued diffusion $\left(\Phi_s\right)_{0 \leq s < \zeta}$ satisfy a linear stochastic differential equation, conditionally on $\left(\phi_s\right)_{0 \leq s < \zeta}$. It is thus well defined up to the explosion time $\zeta$ of the $T^1\Omega M$-valued $\Theta$-diffusion.

This point being clarified, we shall work freely in the sequel with $\Theta$-diffusions on $\Omega M$.

### 3. A First Non-explosion Criterion

We give in this section a simple non-explosion criterion, well-suited to investigate the behaviour of the $\Theta$-diffusions in the largely used class of globally hyperbolic spacetimes. A Lyapunov function is introduced for that purpose, and leads to a non-explosion criterion of a different nature than the typical Riemannian criteria mentioned in the introduction.

The idea is roughly the following: if we can find a function $f = f(\Phi)$ which has compact level sets $\{f \leq \lambda\}$, and does not increase along the trajectories, then the dynamics cannot explode. This was noted first by Khasminsky in a stochastic context; we state his observation here for the relativistic diffusions.

**Lemma 3** (Khasminsky). If there exists a non-negative function $f$ on $\Omega M$ and a positive constant $C$ such that $G_\Theta f \leq C f$, and $f$ goes to infinity along any timelike path leaving any compact in a finite time, then the $\Theta$-diffusion has almost-surely an infinite lifetime.

**Proof** – The condition $G_\Theta f \leq C f$ implies that the real-valued process $\left(e^{-Cs} f(\Phi_s)\right)_{s < \zeta}$ is a non-negative supermartingale. Denote by $\tau_n$ the (possibly infinite) exit time from the level set $\{f \leq n\}$. By optional stopping, we have

$$
f(\Phi_0) \geq \mathbb{E}[e^{-C \tau_n} f(\Phi_{\tau_n})] = n \mathbb{E}[e^{-C \tau_n}].
$$

This implies that $\tau_n$ goes to infinity as $n$ goes to infinity; as $\zeta = \lim_{n \to \infty} \tau_n$, this proves Khasminsky’s statement. □

As $\Theta$-diffusions have no a priori reason not to explode, such a Lyapunov function will generally not exist. Yet, it is possible to construct such a function in some classes of spacetimes of interest for cosmology and theoretical physics. We give below two such examples.
The construction of the function $f$ uses the same recipe in both cases: if there exists an intrinsic distinguished future-directed timelike $C^1$ vector field $U \in T^1 \mathcal{M}$, we can define

$$f(\Phi) := g_m(U_m, \dot{m});$$

recall that $\pi_1(\Phi) = (m, \dot{m}) \in T^1 \mathcal{M}$. For this choice of $f(\Phi)$, which is the hyperbolic angle between $U$ and $\dot{m}$, we have $f \geq 1$, and

$$H_0 f(\Phi) = \nabla_{\dot{m}}(g(U, \dot{m})) = g(\nabla_{\dot{m}} U, \dot{m}).$$

The following lemma shows why $f$ is a good choice to apply Khasminsky’s criterion.

**Lemma 4.** We have on $\Omega \mathcal{M}$:

$$\frac{1}{2} \sum_{j=1}^2 V_j (\Theta V_j f) = \frac{d}{2} \Theta f + \frac{1}{2} (f \dot{m}^k - U^k) \frac{\partial \Theta}{\partial \dot{m}^k}.$$

**Proof** – Choose local coordinates for which $U = \partial_{x^0}$, so $f(\Phi) = \dot{m}^0 = e_0^0$. Using (2.1), we have thus locally:

$$V_j f = \left( e_j^k \frac{\partial}{\partial e_j^0} + e_0^k \frac{\partial}{\partial e_j^k} \right) e_0^0 = e_0^j, \quad V_j^2 f = e_0^0 = f,$$

and

$$\sum_{j=1}^d (V_j \Theta)(V_j f) = \sum_{j=1}^d e_0^j e_j^k \frac{\partial \Theta}{\partial \dot{m}^k} = (\dot{m}^0 \dot{m}^k - g^{0k}) \frac{\partial \Theta}{\partial \dot{m}^k} = (f \dot{m}^k - U^k) \frac{\partial \Theta}{\partial \dot{m}^k}.$$

It follows from (2.4) and (3.2) that

$$g(\nabla_{\dot{m}} U, \dot{m}) + \frac{d}{2} \Theta f + \frac{1}{2} (f \dot{m}^k - U^k) \frac{\partial \Theta}{\partial \dot{m}^k} \leq (C - \frac{d}{2} \Theta) g(U, \dot{m}).$$

Khasminsky’s criterion will thus guarantee the non-explosion of the $\Theta$-diffusion provided $f$ explodes along exploding trajectories and there exists a positive constant $C$ such that

$$g(\nabla_{\dot{m}} U, \dot{m}) + \frac{d}{2} (f \dot{m}^k - U^k) \frac{\partial \Theta}{\partial \dot{m}^k} \leq (C - \frac{d}{2} \Theta) g(U, \dot{m}).$$

In order to turn this criterion into an effective tool, we first restrict ourselves to the following general class of spacetimes. This inequality becomes particularly simple when $\Theta$ depends only on the base point $m \in \mathcal{M}$.

### 3.1. Globally hyperbolic spacetimes

This class of cosmological models is characterized by the existence of a global time function (that is a function $\tau : \mathcal{M} \to \mathbb{R}$, with timelike gradient) such that it has connected spacelike level sets $\{\tau = t\}$ of $\tau$, and each integral curve of the vector field $\nabla \tau$ meets each level set of $\tau$ in exactly one point. Thus $\mathcal{M}$ is diffeomorphic to the product $I \times S$ of an interval $I$ and a $d$-dimensional manifold $S$. Without loss of generality, we can suppose the interval $I$ unbounded from above. With the example of Minkowski spacetime in mind, we see that a given spacetime may have an infinity of time functions; they are not intrinsically associated with the geometry.

Yet, we can take for vector field $U$ in this setting the gradient of the time function $\tau : m = (t, x) \in I \times S \mapsto t$, so

$$f(\Phi) = g(U, \dot{m}) = \nabla_{\dot{m}} \tau = \dot{m}^0 = \dot{t} > 0.$$ 

There is no hope, though, to prove Inequality (3.3) without specifying further the model, as the time function is not intrinsically defined. To proceed further, we shall look at the subclass of **generalized warped product spacetimes**, in which the time function is supplied...
by the model and can be seen as an absolute time. These universes are globally hyperbolic spacetimes \( \mathcal{M} = I \times S \) whose metric tensor has the form

\[
g_m(\dot{m}, \ddot{m}) = a_m^2 |\dot{m}_0| - h_m(\dot{m}_0, \dot{m}_0),
\]

where \( \dot{m}_0 \) is the image of \( \dot{m} \in T^1_0 \mathcal{M} \) by the differential of the first projection \( I \times S \to I \) and \( \dot{m}_0 \) the image of \( \dot{m} \) by the differential of the second projection \( I \times S \to S \). Write \( m = (t, x) \in I \times S \). The function \( a \) is a positive \( C^1 \) function on \( \mathcal{M} \), assumed to be bounded on any subset \( I' \times S \) where \( I' \) is bounded from above, and \( h_m \) is a positive-definite scalar product on \( T_xS \), depending on \( m \) in a \( C^1 \) way. This class of spacetimes contains all Robertson-Walker spacetimes (hence in particular de Sitter and Einstein-de Sitter spacetimes, and the universal covering of the anti-de Sitter spacetime).

**Theorem 5.** Let \( (\mathcal{M}, g) \) be a generalized warped product spacetime. If the function

\[
T^1 \mathcal{M} \ni (m, \dot{m}) \longmapsto \nabla_{\dot{m}} \log a - \frac{d}{4} \Theta(m, \dot{m}) - \frac{1}{4} \left( m^k \frac{\partial \Theta}{\partial m^k} - \frac{1}{a^2(m) \dot{m}_0^2} \frac{\partial \Theta}{\partial \dot{m}_0} \right)
\]

is bounded below, then the \( \Theta \)-diffusion almost-surely does not explode.

**Proof** – • We first check that if the \( \Theta \)-diffusion has a finite lifetime \( \zeta \) then \( f(\Phi_s) \) explodes at time \( \zeta^- \). To that end, consider a timelike trajectory \( \gamma = (m_s, \dot{m}_s)_{0 \leq s < T} = (t_s, x_s, \dot{m}_s)_{0 \leq s < T} \) in \( T^1_0 \mathcal{M} \), defined on some semi-open interval \( [0, T) \), and such that \( \frac{d}{ds}m_s = \dot{m}_s \) and \( f(\gamma_s) = t_s \) is bounded above by some positive constant \( C \). It follows that \( t_0 \leq t_s \leq t_0 + CT \), and \( h_{m_s}(\dot{x}_s, \dot{x}_s) \leq C^2 a_{m_s}^2 \). This entails that \( (x_s)_{0 \leq s < T} \) cannot exit a bounded region of \( S \), and so that \( \gamma \) must be trapped in a finite union of sets of the form \( J^+(m_0) \cap J^-(g_j) \), for some \( g_j \in \mathcal{M} \). A such a union of sets is compact in a hyperbolic spacetime (see for instance \([HE73]\), Section 6.6), \( \gamma \) is trapped in a compact set. Would \( \gamma \) explode, it would have a cluster point at which the strong causality would fail, leading to a contradiction as globally hyperbolic spacetimes are strongly causal \((HE73, \text{Section 6.6})\).

• The condition of the theorem is a rephrasing of the local condition \((3.3)\). To see that, let us work in a neighbourhood \( V = [t_1, t_2] \times V \) of a given point \( m_0 \), and choose coordinates \( x^i \) on \( V \); this provides coordinates \( (t, x^i) \) on \( V \), which induce coordinates on \( T^1V \): for \( m \in V \) and \( \dot{m} \in T^1_0V \), write \( \dot{m} = \dot{m}_0 \partial_t + \sum_{1 \leq j \leq d} \dot{m}_j \partial_{x_j} \).

Note first that since \( U = a^{-2} \partial_t \), we have

\[
\nabla_{\dot{m}_0} U = \nabla_{\dot{m}_0} (a^{-2}) \partial_t + a^{-2} \nabla_{\dot{m}_0} \partial_t.
\]

Using Christoffel symbols \( \Gamma^i_{jk} \), we have

\[
(\nabla_{\dot{m}_0} \partial_t) = \nabla_{\dot{m}_0} (a^{-2}) \delta^0_0 + a^{-2} \dot{m}_0 \Gamma^0_0,
\]

for \( \alpha \in \{0, ..., d\} \) and a summation over \( c \) in \( \{0, ..., d\} \); so

\[
H_0f = g(\nabla_{\dot{m}_0} U, m) = \nabla_{\dot{m}_0} (\log a^{-2}) \dot{m}_0 + a^{-2} \dot{m}_0 \Gamma^0_0 g_{\alpha \beta} \dot{m}^\beta.
\]

The explicit formulas for the Christoffel symbols, in terms of the metric, are

\[
\Gamma^0_0 = \partial_t (\log a), \quad \Gamma^0_k = \partial_{x^k} (\log a), \quad \Gamma^i_0 = \frac{1}{2} h_{i \ell} \partial_{x^\ell} (a^2), \quad \Gamma^0_k = \frac{1}{2} h_{i \ell} \partial_t h_{\ell k},
\]
for \( i, k \in \{1, \ldots, d\} \) and a summation over \( 1 \leq \ell \leq d \). We thus have, after simplifications,

\[
H_0 f = -2 \nabla \dot{m}(\log a) \dot{m}^0 + |\dot{m}^0|^2 \partial_\ell (\log a) - \frac{a^{-2}}{2} \dot{m}^k \partial_\ell (h_{\ell k}) \dot{m}^\ell \\
= - |\dot{m}^0|^2 \partial_\ell \log a - 2 \dot{m}^0 \dot{m}^k \partial_\ell \log a - \frac{a^{-2}}{2} \dot{m}^k \partial_\ell (h_{\ell k}) \dot{m}^\ell .
\]

Using the unit pseudo-norm relation \( a^2_m |\dot{m}^0|^2 - h_{\ell k}(m) \dot{m}^k \dot{m}^\ell = 1 \), the above equality becomes:

\[
H_0 f = -|\dot{m}^0|^2 \partial_\ell \log a - 2 \dot{m}^0 \dot{m}^k \partial_\ell \log a - \frac{a^{-2}}{2} |\dot{m}^0|^2 \partial_\ell (a^2) ,
\]

that is, \( H_0 f = -2 \dot{m}^0 \nabla \dot{m} \log a \). The statement of the theorem follows from (3.3).

This result takes a particularly simple form in the case where \( \Theta \) depends only on the base point \( m \), as is the case of the \( R \)-diffusion.

**Corollary 6.** Let \( \mathbb{M} = I \times S \) denote a generalized warped product spacetime and \( \Theta \) be a bounded non-negative function on \( \mathbb{M} \). Then the \( \Theta \)-diffusion does not explode if \( \nabla a \) is everywhere non-spacelike and future-directed.

**Proof** – The condition of Theorem 5 reads in that case: “\( T^1 \mathbb{M} \ni (m, \dot{m}) \mapsto \nabla \dot{m} \log a \) is bounded below”. To rephrase this condition into the more synthetic condition of the statement, let us work in local coordinates, \( (t, x) \) and \( (\bar{t}, \bar{x}) \) for \( m \) and \( \dot{m} \) respectively.

We have \( \dot{t} = a^{-1} \text{chr} \) and \( \bar{t} = (\text{shr} \sigma) \), for some \( r \in \mathbb{R} \) and \( \sigma \in T_x S \) with \( |\sigma|_{h(m)} = 1 \).

Define \( u := \partial_\ell \log a \) and \( v := \partial_\ell \log a \in T_x S \equiv \mathbb{R}^d \). Then the condition of Theorem 5 reads : \( u a^{-1} \text{chr} - (v \sigma^r) \text{shr} \geq C \), for any \( r \) and \( \sigma \). Letting \( r \to \pm \infty \), gives \( a^{-1} u \geq |v \sigma^r| \geq 0 \). As the constant \( C \) can be taken negative without loss of generality, the reciprocal is clear. Now, since \( \max_{|\sigma|_{h(m)} = 1} |v \sigma^r| = |v|_{h^{-1}(m)} \), the condition reads:

\[
a^{-1} u \geq |v|_{h^{-1}(m)} .
\]

Finally, as \( \nabla = (a^{-2} \partial_\ell , -h^{ij} \partial_x j) \), the vector \( \nabla \log a = (a^{-2} u , -h^{ij} v_j) \) has pseudo-norm \( g(\nabla \log a, \nabla \log a) = a^{-2} u^2 - |v|^2_{h^{-1}(m)} \geq 0 \).

This criterion applies in particular to \( \Theta \)-diffusions in Robertson-Walker spacetimes, recovering the results of Angst, [Ang09], who proceeded by direct analysis of the stochastic differential equations of the dynamics.

### 3.2. Perfect fluids.

Our second class of examples where to apply Lyapounov’s method to prove non-explosion will be the set of spacetimes with normal matter whose energy-momentum tensor \( T \) is that of a perfect fluid. They are characterized by the datum of a timelike vector field \( U \), the four velocity of the fluid, and two functions \( \rho \) and \( p \) on \( \mathbb{M} \), respectively the energy density and pressure of the fluid. See [HE73], [BEE96]. We have then \( T = \rho U \otimes U + p (g + U \otimes U) \), or in local coordinates,

\[
T_{ij} = (\rho + p) U_i U_j + p g_{ij} .
\]

Such a spacetime is said to be of **perfect fluid type**. Notice that contrarily to the globally hyperbolic spacetimes no topological assumption is made on a perfect fluid type spacetime.

Gödel’s universe is such a spacetime. This is the manifold \( \mathbb{R}^4 \) with the metric \( ds^2 = dt^2 - dx^2 + \frac{1}{2} e^{2\sqrt{2} \omega x} dy^2 - dz^2 - 2 e^{\sqrt{2} \omega x} dt \ dy \), where \( \omega > 0 \) is a constant. It is a solution to Einstein’s equation with cosmological constant \( \omega^2 \) and represents a pressure free perfect fluid. It has energy-momentum tensor \( T = U \otimes U \), where \( (U_j) = (\sqrt{2} \omega , 0, \sqrt{2} \omega e^{\sqrt{2} \omega x}, 0) \).
represents the four-velocity covector of the matter, and $\omega$ is the vorticity of this field. This spacetime has constant scalar curvature $2\omega^2$. See Section 2.4 in \[Fra09\]. As above, the function $f$ is defined by Formula (3.1) and can be used as a Lyapounov function under some conditions. The computations made in Section 3.1 work equally well in that setting and lead to the following results.

**Proposition 7.** Let $(\mathbb{M}, g)$ be a Lorentzian manifold of perfect fluid type, and $f$ defined by Formula (3.1). Suppose $f$ goes almost-surely to infinity along any exploding timelike path. If there exists a constant $C$ such that
\[
H_0 f + \frac{1}{2} \Theta f + \frac{1}{2} \left( f \dot{m}^k - U^k \right) \frac{\partial \Theta}{\partial m^k} \leq C f,
\]
then the $\Theta$-diffusion has almost-surely an infinite lifetime.

In the particular case of Gödel universe, the gradient $\nabla U$ of the velocity vanishes (since $U^i = \delta_0^i$), so that $H_0 f = 0$, by Formula (3.2); and $f$ is the square root of the energy.

**Corollary 8.** Let us work in Gödel universe and suppose that $3\Theta + \left( \dot{m}^k \frac{\partial \Theta}{\partial m^k} - \frac{1}{f} \frac{\partial \Theta}{\partial m^k} \right)$ is bounded above in $T^1 \mathbb{M}$. Then the $\Theta$-diffusion has almost-surely an infinite lifetime. This condition holds in particular if $\Theta(\Phi) = \Theta(m)$ depends only on the base point and is bounded, as this is the case for the basic relativistic diffusion and the $R$-diffusion in Gödel universe.

Note that this criterion does not apply to the energy diffusion in Gödel’s universe. Indeed one can see in that case (see Section 2.4 of \[Fra09\]) that the above quantity is equal to $5\Theta - 4\omega^2$ and that the energy $\Theta$ is unbounded along the trajectories of the energy diffusion.

**Remark 9.** In Einstein-de Sitter spacetime the energy diffusion explodes with positive probability, as proved in Proposition 5.4.2 of \[FLJ10\]. (This Robertson-Walker universe is both a warped product and a perfect fluid type spacetime.) Consult \[Bai11\] for a first study of stochastic incompleteness for relativistic diffusions.

### 4. $b$-Completeness

The study of dynamics in the orthonormal frame bundle is not new in general relativity and essentially dates back to Cartan’s moving frame method. However, B.G. Schmidt \[Sch71\] was the first to notice that the geometry of $\mathbb{OM}$ itself may be used to provide a conceptual framework in which studying the nature of spacetime singularities. For that purpose, he introduced on the parallelizable manifold $\mathbb{OM}$ a Riemannian metric, turning $\{H_0, ..., H_d, (V_{ij})_{0 \leq i < j \leq d}\}$ into a Riemannian orthonormal basis, and called it the bundle metric, or $b$-metric. The completeness of this metric structure on $\mathbb{OM}$ can essentially be phrased in terms of $\mathbb{M}$-valued paths. To state that fact, recall that one can associate to any $\mathbb{M}$-valued $C^1$ path $\gamma : [0, T] \to \mathbb{M}$ and $e \in \mathbb{O}_{\gamma_0} \mathbb{M}$ a unique horizontal lift $\gamma^\uparrow : [0, T) \to \mathbb{OM}$ of $\gamma$, starting from $(\gamma_0, e)$, and charactarized by the properties
\[
\frac{d}{ds} \gamma_s^\uparrow \in \text{span}(H_0, ..., H_d), \quad \text{and} \quad \pi_0(\gamma_s^\uparrow) = \gamma_s, \text{ for all } s \in [0, T).
\]

The $S_e$-length of $\gamma$ is defined as the Riemannian length of its horizontal lift $\gamma^\uparrow$; it depends on $e \in \mathbb{O}_{\gamma_0} \mathbb{M}$. In other words, given $e \in \mathbb{O}_{\gamma_0} \mathbb{M}$, seen as orthonormal in the Euclidean sense, the $S_e$-length of the $\mathbb{M}$-valued $C^1$ path $\gamma$ is the Euclidean length of its anti-development in $(T_{\gamma_0} \mathbb{M}, e)$. Although this length depends on $e$, its finiteness is independent of it; we can
thus talk of finite $S$-length of a $C^1$ path without mentioning the frame $e$. Note that in a Riemannian setting the $S_e$-length of a $C^1$ path is its usual Riemannian length.

The above completeness hypothesis is usually called $b$-completeness. The Riemannian version of this statement is trivial as the orthonormal frame bundle with its $b$-metric is complete iff the Riemannian manifold is complete. The Lorentzian situation is more involved as there exists (timelike, spacelike and lightlike) complete Lorentzian manifolds $\mathcal{M}$ which have an incomplete path of bounded acceleration, so $\mathcal{OM}$ is not $b$-complete, see e.g. [Ger68] and [Bee76]. The non-compactness of $SO_0(1,d)$ lies at the core of this phenomenon.

However, the Riemannian view of a Lorentzian manifold provided by Schmidt’s metric offers a bridge to investigate some features of the latter using the tools of Riemannian geometry, as the following proposition shows.

**Proposition 11.** Let $\Theta$ be a bounded function on $\mathcal{M}$. Then the $\Theta$-diffusion does not explode if $\mathcal{OM}$ is $b$-complete.

One should not be confused about that statement. It does not mean that the Riemannian completeness of $\mathcal{OM}$ implies the completeness of its Brownian trajectories, which is false. One cannot assign an $S_e$-length to a Brownian path in $\mathcal{OM}$ as it is not regular enough.

**Proof.** Given a horizontal $C^1$-path $(\rho_s)_{0 \leq s < \zeta}$ in $\mathcal{OM}$, write $\gamma$ for its projection $\pi_0 \circ \rho$ in $\mathcal{M}$, so $\rho = \gamma^1$. For $0 \leq s < T$, denote by $\tau_{0 \rightarrow s}$ the parallel transport operator along the curve $(\gamma^r)_{0 \leq r \leq s}$, with inverse $\tau_{0 \leftarrow s}^{-1}$. Also, denote by $(p_s)_{0 \leq s < T}$ the anti-development of $\gamma$: this $T_{\gamma_0}\mathcal{M}$-valued $C^1$-path is defined for all $s \in [0,T]$ by the formula: $p_s = \int_0^s \tau_{0 \leftarrow r}^{-1} \dot{\gamma}_r \ dr$. Last, we shall denote by $\dot{p} \dot{\gamma}$ the coordinates of $\dot{p}$ in the frame $\rho_0$, and by $\| \cdot \|_{\rho_0}$ the Euclidean norm in $(T_{\gamma_s}\mathcal{M}, \rho_s)$. We have by construction $d\rho_s = \sum_{0 \leq j \leq d} H_j(\rho_s) \dot{p}^j_s \ ds$ and $\dot{\gamma}_s = \tau_{0 \rightarrow s}^{-1} \dot{p}^s_s$, as well as the identity $\| \dot{\gamma}_s \|_{\rho_0}^2 = \| \dot{p}^s_s \|_{\rho_0}^2 = \sum_{0 \leq j \leq d} (\dot{p}^j_s)^2$. The $b$-completeness assumption means that $\gamma$ has a limit $\gamma_T$ in $\mathcal{M}$ at time $T$ if

$$\int_0^T \| \dot{p}_s \|_{\rho_0} \ ds < \infty. \ (4.1)$$

- The basic relativistic diffusion $(m_s, e_s)_{0 \leq s < \zeta}$ is by construction the development in $\mathcal{M}$ of the relativistic Dudley diffusion in Minkowski spacetime, identified with $T_{\gamma_0}\mathcal{M}$, see Theorem 3.2 in [F-LJ-1]. As trajectories of the latter over a time a bounded time interval have almost-surely a finite length in the Euclidean norm associated with any frame of $\mathbb{R}^{1,d}$, the $b$-completeness of $\mathcal{OM}$ ensures the non-explosion of the basic relativistic diffusion.

- For a generic $\Theta$-diffusion, Formula (2.3) implies the existence for each $s \in [0, \zeta]$ of an orthonormal basis $(\varphi_1(s), ..., \varphi_d(s))$ of $\dot{p}^1_s$ in $\mathbb{R}^{1,d}$ such that one has

$$d\dot{p}^k_s = \sum_{j=1}^d \sqrt{\Theta(m_s)} \varphi_j^k(s) \ dw_s^j + \frac{d}{2} \Theta(m_s) \dot{p}^k_s \ ds$$

for some $d$-dimensional Brownian motion $w$. We have used the fact that $\Theta$ depends only on $m$ to simplify the general expression. The path $(p_s, \dot{p}_s)_{0 \leq s < \zeta}$ appears then as a time
change of Dudley’s diffusion, by means of the map \( s \mapsto \inf \left\{ u \mid \int_0^u \Theta(m_r) \, dr > s \right\} \). The result follows for a bounded function \( \Theta \).

This result can be improved in two ways: by relaxing the boundedness hypothesis on \( \Theta \) and by relaxing the geometric completeness assumption. The next section explains how this can be done in a sub-Riemannian framework by using ideas from the theory of reversible Markov processes.

5. A volume growth non-explosion criterion

We prove in this section a non-explosion criterion involving only the volume growth of some sub-Riemannian boxes in \( OM \) and the function \( \Theta \), as described in theorem \[13\] below. This result is proved in Section \[5.4\] following Takeda’s method, as improved recently by Hsu and Qin in \[HQ10\]. Yet, there is a real difficulty in doing this, as we are working with a non-symmetric, hypoelliptic diffusion, and on a principal bundle with non-compact fibres. To overcome these difficulties, we introduce a sub-Riemannian structure on \( OM \), well-adapted to our setting, and which will somehow play for us the role of the missing Lorentzian distance.

5.1. Sub-Riemannian framework and main results.

5.1.1. Sub-Riemannian distance function. We have seen in \[4\] that the completeness of the natural Riemannian metric of the parallelizable manifold \( OM \) implies the stochastic completeness of all the \( \Theta \)-diffusions with a bounded \( \Theta \). One can significantly improve that conclusion by working with the sub-Riemannian structure on \( OM \) induced by the field of \((d+1)\)-planes generated by the vector fields \( H_0, V_1, \ldots, V_d \). In that setting, one can assign a length only to \( C^1 \) paths \( \rho : [0, T] \to OM \) whose tangent vector belong at any time \( s \) to the vector space spanned by \( H_0, V_1, \ldots, V_d \) in \( T_\rho OM \), say \( \dot{\rho}_s = \dot{\rho}_s^0 H_0(\rho_s) + \dot{\rho}_s^1 V_1(\rho_s) + \cdots + \dot{\rho}_s^d V_d(\rho_s) \).

Such a path is said to be admissible; its length is then defined as \( \int_0^T (\sum_{i=0}^d (\dot{\rho}_s^i)^2) \, ds \). The sub-Riemannian distance between two points of \( OM \) is defined as the infimum of the length of the admissible paths joining these two points, with the convention \( \inf \emptyset = +\infty \). Chow’s theorem \[Cho39\] ensures that the sub-Riemannian distance function \( D(\cdot, \cdot) \) is finite and continuous in its two arguments if (see e.g. \[Mon02\]) the Lie algebra generated by \( H_0, V_1, \ldots, V_d \) has full dimension, which holds here. Fix a reference point \( \Phi_{ref} \in OM \).

\( (H) \) Completeness hypothesis. The closed boxes \( B_\lambda := \{ D(\Phi_{ref}, \cdot) \leq \lambda \} \) are compact for any \( \lambda > 0 \).

This completeness hypothesis rules out the pathological examples of Geroch \[Ger68\] and Beem \[Bee76\]; it does not depend on the arbitrary choice of \( \Phi_0 \). Unlike its Riemannian analogue, the sub-Riemannian distance function \( D(\cdot, \cdot) \) is not smooth in any neighbourhood of \( \Phi_{ref} \), \[Mon02\]; however, it is a viscosity solution of the equation

\[
|H_0D|^2 + |V_1D|^2 + \cdots + |V_dD|^2 = 1
\]

on \( OM\setminus\{\Phi_{ref}\} \) (see e.g. theorem 2 in \[Dra07\]; we do not use that fact in the sequel). We shall use that quantitative information in \[5.4\] under the classical form given in the following proposition.

**Proposition 12.** Fix \( \lambda > 0 \). One can associate to any positive constant \( \eta \) a smooth function \( F : OM \to \mathbb{R}_+ \) such that

\[
\max_{\Phi \in B_\lambda} |F(\Phi) - D(\Phi_{ref}, \Phi)| \leq \eta
\]
and we have on $B_\lambda$

$$|H_0 F|^2 + |V_1 F|^2 + \cdots + |V_d F|^2 \leq 2.$$  

Proof – Let us introduce the Riemannian metric $g_\epsilon$ on $\mathbb{M}$ for which $H_0, H_1, \ldots, H_d$ and the $(V_{ij})_{0 \leq i < j \leq d}$ are orthogonal, with $H_0$ and the $V_{ij} (= V_j)$ of norm 1 and the other vectors of norm $\epsilon^{-1}$. Denote by $D_\epsilon(\cdot) = D_\epsilon(\Phi_{\text{ref}}, \cdot)$ the distance function associated with $g_\epsilon$. It is a 1-Lipschitz-continuous function (with respect to the distance function $D_\epsilon$) which is differentiable almost-everywhere, by Rademacher’s theorem, and has a gradient of norm 1 almost-everywhere:

$$|H_0 D_\epsilon|^2 + |V_1 D_\epsilon|^2 + \cdots + |V_d D_\epsilon|^2 + \epsilon^{-2} \left( \sum_{i=1}^{d} |H_i D_\epsilon|^2 + \sum_{1 \leq i < j \leq d} |V_{ij} D_\epsilon|^2 \right) = 1. \tag{5.1}$$

(Indeed, the set of conjugate points to $\Phi_0$ in $B_\lambda$ is closed and has null measure. In the complementary open set the distance is attained along a unique geodesic whose unit tangent vector at the final point is the gradient of the distance function to $\Phi_0$.) The function $D_\epsilon$ is easily seen to converge uniformly to $D(\Phi_{\text{ref}}, \cdot)$ on the compact box $B_\lambda$ (this is where we need these boxes to be compact); see e.g. §§ 0.8.A and 1.4.D of Gromov’s article [Gr96]. As we have almost-everywhere

$$|H_0 D_\epsilon|^2 + |V_1 D_\epsilon|^2 + \cdots + |V_d D_\epsilon|^2 \leq 1,$$

by (5.1), a standard regularization procedure yields the conclusion. □

5.1.2. Main results. We use the natural volume measure on $\mathbb{OM}$ associated with the Lorentzian structure. It is defined by the formula

$$\text{Vol}(d\Phi) = \text{Vol}_M(dm) \otimes \text{Vol}_m(de), \quad \Phi = (m, e),$$

where $\text{Vol}_M(dm)$ is the Lorentzian volume measure and $\text{Vol}_m(de)$ is the image of a given Haar measure on $SO_0(1, d)$ by the identification of the fibre $\pi_0^{-1}(m)$ with $SO_0(1, d)$ (see e.g. [He73], Section 2.8, for the Lorentzian volume measure). The volume measure $\text{Vol}$ on $\mathbb{OM}$ is uniquely defined up to a multiplicative constant. In order to avoid some unpleasant pathologies, we shall make the following rather mild assumption on the causal structure of spacetime.

Hypothesis. $(\mathbb{M}, g)$ is strongly causal.

It means that any point of $\mathbb{M}$ has arbitrarily small neighbourhoods which no non-spacelike path intersects more than once; see [He73], p.192, or [BEE96].

Theorem 13. Let $(\mathbb{M}, g)$ be a strongly causal Lorentzian manifold satisfying the completeness hypothesis (H). Set $\Theta_r := \sup_{\Phi \in B_r} \Theta(\Phi)$, for any $r > 0$, and suppose

$$\int_0^\infty \frac{r \, dr}{\Theta_r \log(\Theta_r \text{Vol}(B_r))} = \infty. \tag{5.2}$$

Then the $\Theta$-diffusion has almost-surely an infinite lifetime, from any starting point.

Condition (5.2) has the form of the classical non-explosion condition for Brownian motion:

$$\int_0^\infty \frac{r \, dr}{\log \text{Vol}(B_r)} = \infty, \quad \text{first proved by Grigor’yan in [Gr86]},$$

and has precisely that form for $\Theta$ bounded. Note that no topological assumption on $\mathbb{M}$ is needed, contrary to the results of
§3.1. One can give a quantitative version of the above theorem by providing an upper rate function.

**Corollary 14.** Let $\mathbb{M}$ be a strongly causal Lorentzian manifold satisfying the completeness hypothesis (H). Set $h(\rho) \equiv \rho$ if $\Theta \equiv 0$; otherwise, pick a constant $R_0$ such that $\Theta_{R_0} > 0$ and set for $\rho > 0$

$$h(\rho) := \inf \left\{ R > R_0 \mid \int_{R_0}^{R} \log \Theta_r \, dr > \rho \right\}.$$  

Then, given any $\Phi_0 \in \mathcal{O}\mathbb{M}$, there exist $R_0 > 0$ and a positive constant $C$ such that we have $\mathbb{P}_{\Phi_0}$-almost-surely

$$\mathcal{D}(\Phi_0, \Phi_s) \leq C \, h(Cs).$$

We prove Theorem 13 following Takeda’s method, explained in the next section. To adapt it to our setting, we shall introduce in §5.3 a modified $\Theta$-diffusion on some compact space; it is used crucially in the proof of Theorem 13 given in §5.4.

5.2. Takeda’s method.

5.2.1. The main ingredients. Using an idea of Lyons and Zheng, [LZ88], Takeda devised in [Tak89], [Tak91], a remarkably simple and sharp non-explosion criterion for Brownian motion on a Riemannian manifold $\mathbb{V}$. Loosely speaking, his reasoning works as follows. Suppose we have a diffusion $(x_s)_{s \geq 0}$ on $\mathbb{V}$ which is symmetric (with respect to the Riemannian volume measure $\text{Vol}$, say) and conservative; denote by $L$ its generator, and let $f$ be a sufficiently smooth function. Denote by $\mathbb{P}_\text{Vol}$ the measure $\int \mathbb{P}_x \text{Vol}(dx)$ on the path space, where $\mathbb{P}_x$ is the law of the diffusion started from $x$. Fix a time $T > 0$. As the reversed process $(x_{T-s})_{0 \leq s \leq T}$ is an $L$-diffusion under $\mathbb{P}_\text{Vol}$, applying Itô’s formula to both $f(x_s)$ and $f(x_{T-s})$ provides two martingales $M$ and $\tilde{M}$ (with respect to the two different filtrations $\sigma(x_s; 0 \leq s \leq T)$ and $\sigma(x_{T-s}; 0 \leq s \leq T)$ respectively) such that:

$$f(x_s) = f(x_0) + M_s + \int_0^s Lf(x_r) \, dr,$$

$$f(x_s) = f(x_{T-(T-s)}) = f(x_T) + \tilde{M}_{T-s} + \int_0^{T-s} Lf(x_{T-r}) \, dr.$$  

It follows that

$$f(x_T) - f(x_0) = \frac{1}{2}(M_T - \tilde{M}_T).$$

If $\frac{d(M)}{ds}$ and $\frac{d(\tilde{M})}{ds}$ are bounded above, by $1$ say, the previous identity provides a control of $(f(x_T) - f(x_0))$ by the supremum of the absolute value of a Brownian motion over the time interval $[0, T]$.

Back to the non-explosion problem for Brownian motion on $\mathbb{V}$, fix a point $m \in \mathbb{V}$ and a radius $R > 1$, and consider the Brownian motion $(x_s)_{s \geq 0}$ reflected on the boundary of the Riemannian ball $B(m; R)$, started under its invariant measure $1_{B(m; R)}\text{Vol}$. It is a symmetric conservative diffusion; denote by $\mathbb{P}_{B(m; R)}$ its law. Using the Dirichlet forms approach to symmetric diffusions one can apply the above reasoning to the (non-smooth, but 1-Lipschitz) Riemannian distance function $d(m, .)$, which gives the estimate

$$\mathbb{P}_{B(m; R)} \left( x_0 \in B(m; 1), \sup_{s \leq T} d(m, x_s) = R \right) \leq \text{Vol}(B(m; R)) \times 2 \mathbb{P} \left( \sup_{s \leq T} |B_s| > R \right).$$
But as the Brownian motion on \( V \) behaves in the ball \( B(m; R) \) as the Brownian motion reflected on the boundary of \( B(m; R) \), the above inequality also gives an upper bound for the probability that the Brownian motion on \( V \), started uniformly from \( B(m; 1) \), exits the ball \( B(m; R) \) before time \( T \). Combining this estimate with the Borel-Cantelli lemma, Takeda proved that the Brownian motion on \( V \) is conservative provided

\[
\liminf_{R \to \infty} R^{-2} \log \text{Vol}(B(m; R)) < \infty,
\]

re-proving in a simple way a criterion due to Karp and Li. Takeda’s method has been refined by several authors, culminating with Hsu and Qin’s recent work [HQ10], who give an elegant and simple proof of a sharp non-explosion criterion, due to Grigor’yan [Gri86], for Brownian motion on a Riemannian manifold in terms of volume growth, as well as an escape rate function. We shall follow their method to deal with relativistic diffusions.

5.2.2. The difficulties. The main difficulty in implementing this approach is in finding what can play the role of the pair “Riemannian distance function – reflected Brownian motion” in our Lorentzian, hypoelliptic framework. We describe in the remainder of this section a non-standard reflection mechanism for a Brownian motion in a Riemannian manifold which will serve us as a guide in the construction of the \( \Theta \)-diffusion reflected on the boundary of the sub-Riemannian boxes, as described in section 5.3.

Brownian motion reflected on the boundary of a ball \( B(m; R) \) is the simplest diffusion process which coincides with Brownian motion on the ball \( B(m; R) \) and has a state space with finite volume. One cannot take a smaller state space if the former property is to be satisfied. Yet, one can make different choices if one is ready to loose the minimality property. To explain that fact, let us suppose that \((\mathbb{V}, g)\) is a Cartan-Hadamard manifold. Given a point \( m \in \mathbb{V} \) let us use the exponential map \( \exp_m \) at \( m \) as a global chart on \( \mathbb{V} \); this identifies the geodesic ball \( B(m; R) \) on \( M \) to the (Euclidean-shaped) ball \( B'(0; R) \) in \( T_m \mathbb{V} \). Given \( \epsilon > 0 \), let us modify the metric on \( B'(0; R + \epsilon) \setminus B'(0; R) \) so as to interpolate smoothly between \( \exp^*_m g \) on \( B'(0; R) \) and the constant metric \( c_m \) outside \( B'(0; R + \epsilon) \) (primed balls refer to the pull-back metric \( \exp^*_m g \)). Denote by \( \widetilde{g} \) the restriction to \( B'(0; R + 2\epsilon) \) of this modified metric, and define the compact space \( \mathbb{K} \) as the quotient of the closed ball \( \overline{B'(0; R + 2\epsilon)} \) by the identification of \( m' \in \partial \overline{B'(0; R + 2\epsilon)} \) and \(-m'\). Then the \( \widetilde{g} \)-Brownian motion on \( \mathbb{K} \) coincides with the \( \exp^*_m g \)-Brownian motion on \( B'(0; R) \) and has a state space with finite \( \widetilde{g} \)-volume \( \text{Vol}_{\widetilde{g}}(\mathbb{K}) = (1 + o(\epsilon)) \text{Vol}_g(B(m; R)) \). The construction of a modified \( \Theta \)-diffusion given in section 5.3 will be reminiscent of the preceding non-standard reflected Brownian motion.

5.3. A modified process. We start our construction of the “reflected” \( \Theta \)-diffusion by constructing the compact space on which it is going to live. Fix for that purpose a reference point \( \Phi_{\text{ref}} \in \Omega M \), the centre of the boxes \( B_\lambda \), and set \( D(\Phi) = D(\Phi_{\text{ref}}, \Phi) \) for all \( \Phi \in \Omega M \). Fix also two positive constants \( \lambda \) and \( \varepsilon \) and consider the relatively compact open region

\[
\mathcal{U} := \{ \lambda < D < \lambda + \varepsilon \} = B_{\lambda+\varepsilon} \setminus B_\lambda.
\]

**Lemma 15.** There exists in \( \mathcal{U} \) a smooth hypersurface \( V \) of \( \Omega M \) separating \( \partial B_\lambda \) from \( \partial B_{\lambda+\varepsilon} \) such that the subset \( V_0 := \{ \Phi \in V \mid H_0(\Phi) \in T_\Phi V \} \) is a smooth hypersurface of \( V \).

The separation property means that \( \partial B_\lambda \cup \partial B_{\lambda+\varepsilon} \) does not intersect \( V \) but any continuous path from \( \partial B_\lambda \) to \( \partial B_{\lambda+\varepsilon} \) hits \( V \). We thank A. Oancea and P. Pansu for their help in proving this statement.
I. BAILLEUL AND J. FRANCHI

Proof – Let us use the function $F$ of Proposition 12 with $\eta < \varepsilon/4$ and $R > \lambda + \varepsilon$, and fix some constants $\eta < \varepsilon_1 < \varepsilon_2 < \varepsilon/2 - \eta$ such that $B_\lambda \subset \{ \varepsilon_1 \leq F - \lambda \leq \varepsilon_2 \} \subset B_{\lambda + \varepsilon}/2$.

The set of regular values of $(F - \lambda)$ is dense in the interval $(\varepsilon_1, \varepsilon_2)$, by Sard’s theorem. Fix a regular value $c \in (\varepsilon_1, \varepsilon_2)$, so the level set $S := \{ F = c \}$ is a smooth hypersurface separating $\partial B_\lambda$ from $\partial B_{\lambda + \varepsilon}/2$.

We shall now be working in $U' \equiv S \times [0, 1/2)$, where we are going to construct the separating hypersurface $V$ as the graph of some function $f : S \to [0, 1/2)$, resorting to the transversality lemma. Denote by $Gr(TU')$ the Grassmannian bundle over $U'$ made up of all the hyperplanes of $TU'$, and associate to any function $f : S \to (0, 1/2)$ the function $G_f : S \to Gr(TU')$ defined by $G_f(m) := \{ (\sigma, df_m(\sigma)) | \sigma \in T_mS \}$. Let $\mathcal{H}$ denote the smooth hypersurface of $Gr(TU')$, made up of all hyperplanes containing $H_0$. Then $G_f^{-1}(\mathcal{H})$ is a smooth hypersurface of Graph($f$) as soon as $G_f$ is transverse to $\mathcal{H}$. Therefore the statement reduces to finding a function $f$ such that $G_f$ be transverse to $\mathcal{H}$.

Consider for that purpose a smooth partition of unity: $1_S = \sum_{j=1}^k \alpha_j$, with $\{ \alpha_j > 0 \} = \psi_j(B'^n)$ diffeomorphic under $\psi_j$ to the unit ball $B' \subset \mathbb{R}^n$ (with $\nu = \dim(\mathcal{O}\mathcal{M}) - 1 = (d + 3)d/2$). Denoting by $\mathcal{A}$ the space of (the restrictions to $B'^n$ of) affine functions on $\mathbb{R}^n$, consider the map $F : \mathcal{A}^n \times S \to Gr(TU')$ defined by the formula

$$G(\varphi_1, \ldots, \varphi_k, m) := G_f(m),$$

where $f = \sum_{j=1}^k \alpha_j \varphi_j \circ \psi_j^{-1}$. This is easily seen to be a submersion. It follows from the transversality lemma that such a $G_f$ is transversal to $\mathcal{H}$ for almost-every $(\varphi_1, \ldots, \varphi_k) \in \mathcal{A}^n$. The graph of the function $f$ corresponding to a small multiple of such a $k$-tuple has the properties of the statement.

Let $O$ be the set of points of the box $B_{\lambda + \varepsilon}$ of the form $\gamma(1)$ for some continuous path $\gamma : [0, 1] \to B_{\lambda + \varepsilon}$ starting from a point of $B_\lambda$ and not hitting $V$; this is an open set with $V$ as a boundary. Denote also by $W$ another smooth hypersurface, separating $V$ from $\partial B_\lambda$ and transverse to $H_0$ except on a relative hypersurface. Let now denote by $\mathcal{O}'\mathcal{M}$ a disjoint copy of the set of past-directed frames:

$$\{ (m, e) \in GLM | e = (e_0, e_1, \ldots, e_d) \text{ such that } (m, (-e_0, e_1, \ldots, e_d)) \in \mathcal{O}\mathcal{M} \},$$

and let $O'$, $V'$, $V'_0$ and $W'$ be the subsets of $\mathcal{O}'\mathcal{M}$ corresponding to $O$, $V$, $V_0$ and $W$. The equivalence relation

$$(m, (e_0, e_1, \ldots, e_d)) \in V \sim (m, (-e_0, e_1, \ldots, e_d)) \in V'$$

defines a manifold structure on the quotient space $(O \cup V) \sqcup (O' \cup V')/\sim$, which we denote by $\mathcal{E}$. Note that $\mathcal{E}$ is compact and that its volume is in between $2 \text{Vol}(B_\lambda)$ and $2 \text{Vol}(B_{\lambda + \varepsilon})$.

Write $\mathcal{V}$ for the image in $\mathcal{E}$ of $V$, and $\mathcal{V}_0$ for the image in $\mathcal{E}$ of $V_0$; define the primed sets $\mathcal{V}'$ and $\mathcal{V}'_0$ accordingly.

Remark 16. The geodesic flow is naturally well defined on $\mathcal{E} \setminus \mathcal{V}_0$, getting instantly from $O$ to $O'$ or from $O'$ to $O$ at its crossings of $\mathcal{V} \setminus \mathcal{V}_0$. Indeed by the above definition, for any $\Phi \in \mathcal{V} \setminus \mathcal{V}_0$, either $H_0(\Phi)$ points outwards seen from $O$ and inwards seen from $O'$, or $H_0(\Phi)$ points inwards seen from $O$ and outwards seen from $O'$. There is however no a priori
convenient way to extend the geodesic flow on $\mathcal{V}_0$. This is the reason why we need to take care of this exceptional set.

We define the \textit{modified relativistic diffusion} on the compact manifold $\mathcal{E}$ as follows. Let $a : B_{\lambda+\varepsilon} \to [0,1]$ be a smooth function equal to 1 on $B_\lambda$, and whose vanishing set is exactly the closed part $\mathcal{C}$ of $\mathcal{U}$ in between $W$ and $V$ (this means that $\mathcal{C}$ is the union of the trajectories $(\gamma_s)_{s \in (0,1)} \subset \mathcal{U}$ of continuous paths $\gamma$ such that $\gamma_0 \in W$, $\gamma_1 \in V$, and $(\gamma_s)_{s \in (0,1)}$ does not intersect the oriented hypersurface $W \cup V$). We extend to $\mathcal{E}$ the restriction of $a$ to $O \cup V$, by setting $a(e') = a(e)$ for $e' = (m, (-e_0, e_1, \ldots, e_d)) \in \mathcal{O}'\mathcal{M}$ and $e = (m, (e_0, e_1, \ldots, e_d)) \in \mathcal{O}\mathcal{M}$. We define the generator of the modified diffusion to be the following variant of $G_\Theta$:

\begin{equation}
G := H_0 + \frac{1}{2} \sum_{j=1}^{d} V_j (a \Theta V_j).
\end{equation}

Denote by $\text{Vol}_\mathcal{E}$ (resp. $\text{Vol}_V$, $\text{Vol}_W$) the natural volume element on $\mathcal{E}$ (resp. $V$, $W$).

**Lemma 17.** For $\text{Vol}_\mathcal{E}$-almost all starting point $\Phi_0 \in \mathcal{E}$, the modified relativistic diffusion is a well-defined $\mathcal{E}$-valued process having an almost-surely infinite lifetime.

**Proof.** This modified diffusion has generator $G_\Theta$ in $B_\lambda$ and in its mirror copy $B'_\lambda$, and reduces to the geodesic flow in the region $\{a = 0\}$ in between $W$ and $W'$. After remark 10 we need first make sure that the set $\mathcal{V}_0 \cup \mathcal{V}'_0$ of bad points is polar.

Let $\mathcal{N}$ and $\mathcal{N}'$ be the orbits in the region $\{a = 0\}$ of $\mathcal{V}_0$ and $\mathcal{V}'_0$ by the geodesic flow. They have, as a consequence of lemma 15 null $\text{Vol}_\mathcal{E}$-measure. But as the modified diffusion started from any $\Phi_0 \in \{a > 0\}$ is hypoelliptic, its hitting distribution of $W \cup W'$ has a density with respect to $\text{Vol}_{W \cup W'}$. It follows that the modified diffusion, started from any point of $\Phi_0 \setminus (\mathcal{N} \cup \mathcal{N}')$, will almost surely never hit $\mathcal{N} \cup \mathcal{N}'$, proving that this $\mathcal{E}$-valued process is well-defined.

It can behave in two ways as it approaches its lifetime: either crossing infinitely many times $\mathcal{V}$, or remaining eventually in a compact subset of $O$ or $O'$. In the latter case, its projection on $\mathcal{M}$ is a (future or past-directed) timelike path confined in a compact subset of $O$. As such it has a cluster point at which the strong causality condition cannot hold, preventing $\mathcal{M}$ from being strongly causal, a contradiction.

In the former case, either the path eventually remains in the region $\{a = 0\}$, or it performs before some finite proper time an infinite number of crossings from $W \cup W'$ to $\mathcal{V}$. Since the geodesic flow does not explode in $\{a = 0\}$, we are left with the latter possibility. It cannot lead to explosion either, since the geodesic flow needs a traveling time bounded away from 0 to travel from $W \cup W'$ to $\mathcal{V}$. $>$

Note that the volume measure $\text{Vol}_\mathcal{E}$ of the compact manifold $\mathcal{E}$ is an invariant finite measure for the modified diffusion.

### 5.4. Crossing times and escape rate of $\Theta$-diffusions.

Fix a reference point $\Phi_{\text{ref}} \in \mathcal{O}\mathcal{M}$, and set $D(\cdot) = D(\Phi_{\text{ref}}, \cdot)$. Let us emphasize that $D$ is a two points function, so it is easy to pass from $D(\Phi_{\text{ref}}, \Phi)$ to $D(\Phi_0, \Phi)$, or the other way round, using the triangle inequality, for any $\Phi_0 \in \mathcal{O}\mathcal{M}$.
Given an increasing sequence \((R_n)_{n \geq 1}\) of positive reals, set \(\tau_0 = 0\) and associate to each \(R_n\) the exit time \(\tau_n\) from the box \(B^{(n)} := \{D \leq R_n\}\).

It takes the diffusion an amount of proper time \((\tau_n - \tau_{n-1})\) to go from the box \(B^{(n-1)}\) to the box \(B^{(n)}\). The strategy in [HQ10] is to estimate \(\mathbb{P}_\Phi(\tau_n - \tau_{n-1} \leq t_n)\) for a suitably chosen deterministic sequence \(\{t_n\}_{n \geq 0}\) of increments of time. Set for \(n \geq 1\):

\[
T_n := \sum_{k=1}^{n} t_k, \quad \text{and} \quad r_n := R_n - R_{n-1}.
\]

If one can show that

\[
\sum_{n \geq 1} \mathbb{P}_\Phi(\tau_n - \tau_{n-1} \leq t_n) < \infty
\]

for a convenient choice of the sequences \((R_n)_{n \geq 1}\) and \((T_n)_{n \geq 1}\), then the Borel-Cantelli lemma tells us that the diffusion does not exit \(B^{(n)}\) before time \(T_n\), for \(n\) large enough, preventing explosion. Following [HQ10], we are going to consider the events

\[
E_n := \{\tau_n - \tau_{n-1} \leq t_n, \tau_n \leq T_n\},
\]

so as to be able to use our modified process run backwards from the fixed time \(T_n\), when estimating the probability that the process crosses from \(B^{(n-1)}\) to \(B^{(n)}\) not too fast. Lemma 2.1 of [HQ10] (an application of the Borel-Cantelli lemma) justifies that considering these events leads to the same non-explosion conclusion as (5.4). We recall it here for the reader’s convenience.

**Lemma 18 ([HQ10]).** Fix \(\Phi \in \mathcal{OM}\). If \(\sum_{n \geq 1} \mathbb{P}_\Phi(E_n) < \infty\), then there exists \(\mathbb{P}_\Phi\)-almost-surely \(\delta\) such that \(\tau_n \geq T_n - \delta\), for all \(n \geq 1\).

We shall use the results of Sections 5.1.1 and 5.3 to prove the fundamental estimate of Proposition 19 below. Given any compact subset \(B\) of \(\mathcal{OM}\), denote by \(\mathbb{P}_B\) the law of the relativistic diffusion in \(\mathcal{OM}\) started under the uniform probability in \(B\):

\[
\mathbb{P}_B(\cdot) = \frac{1}{\text{Vol}(B)} \int_B \mathbb{P}_\Phi(\cdot) \text{Vol}(d\Phi).
\]

Similarly, and given any compact subset \(A\) of \(\mathcal{E}\), write \(\mathbb{Q}_A\) for the law of the modified \(\Theta\)-diffusion in \(\mathcal{E}\) started under the uniform probability in \(A\).

**Proposition 19.** There exists a constant \(C\) such that we have for any \(n \geq 1\):

\[
\mathbb{P}_B^{(1)}(\tau_n - \tau_{n-1} \leq t_n, \tau_n \leq T_n) \leq C \frac{\text{Vol}(B^{(n)})}{\text{Vol}(B^{(1)})} \frac{T_n \sqrt{\hat{\Theta}_n / t_n}}{(r_n - 1 - 4t_n)} \exp \left[-\frac{(r_n - 1 - 4t_n)^2}{32 \hat{\Theta}_n t_n}\right],
\]

where \(\hat{\Theta}_n\) denotes the supremum of \(\Theta\) over the box \(\{D \leq R_n + 1\}\).

The proof mimics Takeda’s original proof, as adapted by Hsu and Qin in [HQ10], with the noticeable difference that we are working with a non-symmetric, non-elliptic diffusion.
Proof — We start by embedding the box $B^{(n)}$ into the set $\mathcal{E}^{(n)}$ constructed in Section 5.3, with $\lambda = R_{n}$ and $\varepsilon = \frac{1}{2}$, say. From now on we work on the path space over $\mathcal{E}^{(n)}$ and use the coordinate process $X$, whose filtration is denoted by $(\mathcal{F}_s)_{s \geq 0}$. We still denote by $\tau_n$ the exit time from (the image in $\mathcal{E}^{(n)}$ of) $B^{(n)}$; the event

$$E_n := \{ \tau_n - \tau_{n-1} \leq t_n, \tau_n \leq T_n \}$$

belongs to $\mathcal{F}_n$. As explained above in Section 5.2, the proof has two main ingredients, the first of which is Inequality (5.5) below, where $\mathbb{Q}_{\mathcal{E}^{(n)}}$ denotes the distribution of the modified $\Theta$-diffusion in $\mathcal{E}^{(n)}$, with generator $\mathcal{G}$ given in (5.3).

As the $\Theta$-diffusion and the modified $\Theta$-diffusion have the same law before the stopping time $\tau_n$, we have $\mathbb{P}_{B^{(n)}}(E_n) = \mathbb{Q}_{B^{(n)}}(E_n) \leq 2 \mathbb{Q}_{\mathcal{E}^{(n)}}(E_n)$, and so

$$\mathbb{P}_{B^{(n)}}(E_n) \leq 2 \frac{\text{Vol}(B^{(n)})}{\text{Vol}(B^{(1)})} \mathbb{Q}_{\mathcal{E}^{(n)}}(E_n),$$

by the obvious inequality $\mathbb{P}_{B^{(n)}}(E_n) \leq \frac{\text{Vol}(B^{(n)})}{\text{Vol}(B^{(1)})} \mathbb{P}_{B^{(1)}}(E_n)$. The second ingredient involves the Lyons-Zheng decomposition of $\mathcal{D}(X_s)$ under $\mathbb{Q}_{\mathcal{E}^{(n)}}$. As $\mathcal{D}$ is not a priori sufficiently regular to use Itô’s formula, we apply it to its smooth approximation $F$ constructed in Proposition 12 (with $R = R_{n}$ and $\eta = \frac{1}{2}$). As the process $(X_{T_n-s})_{0 \leq s \leq T_n}$ is under $\mathbb{Q}_{\mathcal{E}^{(n)}}$ a homogeneous diffusion process with generator $\mathcal{G}^* = -H_0 + \sum_{j=1}^{d} V_j (a \Theta V_j)$, it follows from Itô’s formula that there exists two martingales $(M_s)_{0 \leq s \leq T_n}$ and $(\tilde{M}_s)_{0 \leq s \leq T_n}$, with respect to the forward and backward filtrations of the process respectively, such that

$$F(X_s) = F(X_0) + M_s + \int_0^s \mathcal{G} F(X_r) \, dr,$$

$$F(X_s) = F(X_{T_n-(T_n-s)}) = F(X_{T_n}) + \tilde{M}_{T_n-s} + \int_s^{T_n} \mathcal{G}^* F(X_r) \, dr,$$

with

$$\langle M \rangle_s = \sum_{j=1}^{d} \int_0^s a(X_r) \Theta(X_r) |V_j F|^2(X_r) \, dr \leq 4 \tilde{\Theta}_n s,$$

$$\langle \tilde{M} \rangle_s = \sum_{j=1}^{d} \int_0^s a(X_{T_n-r}) \Theta(X_{T_n-r}) |V_j F|^2(X_{T_n-r}) \, dr \leq 4 \tilde{\Theta}_n s.$$

Setting $M'_s := \tilde{M}_{T_n-s}$ and noting that $\mathcal{G} - \mathcal{G}^* = 2H_0$, we thus have

$$d(F(X_s)) = d\left(\frac{M_s + M'_s}{2}\right) + H_0 F(X_s) \, ds,$$

with a controlled drift term $|H_0 F| \leq 2$, by Proposition 12. By construction, we have

$$\sup_{0 \leq s \leq t_n} \left| F(X_{\tau_{n-1}+s}) - F(X_{\tau_{n-1}}) \right| \geq r_n - 1$$

on the event $E_n$, where $X$ hits the set $\{ F \geq R_n - \frac{1}{2} \}$ in the time interval $[\tau_{n-1}, \tau_{n-1} + t_n]$. To control the $\mathbb{Q}_{\mathcal{E}^{(n)}}$-probability of $E_n$, we use Hsu and Qin’s trick. Cut the interval $[0, T_n] = \bigcup_{k=1}^{\ell_n} [(k-1)t_n, kt_n]$ into $\ell_n := T_n/t_n$ sub-intervals of length $t_n$ (to lighten the
notations, we shall neglect the fact that \( \ell_n \) may not be an integer; this fact causes no trouble but notational), and write on each event \( \{(k-1)t_n \leq \tau_{n-1} \leq k t_n\} \)
\[
F(X_{\tau_{n-1}+s}) - F(X_{\tau_{n-1}}) = F(X_{\tau_{n-1}+s}) - F(X_{kt_n}) + F(X_{kt_n}) - F(X_{\tau_{n-1}}).
\]
This simple remark shows that the event \( \{ \sup_{0 \leq s \leq t_n} |F(X_{\tau_{n-1}+s}) - F(X_{\tau_{n-1}})| \geq r_n - 1 \} \) is included in one of the \( \ell_n \) events \( \{ \sup_{0 \leq |s| \leq t_n} |F(X_{ct_n+s}) - F(X_{ct_n})| \geq \frac{r_n}{2} \} \), where \( 1 \leq k \leq \ell_n \). By (5.7) and the inequality \(|H_0F| \leq 2\), the \( k^{th} \) of these events is included in the union \( A_k \cup \tilde{A}_k \), where
\[
A_k := \left\{ \sup_{0 \leq |s| \leq t_n} |M_{ct_n+s} - M_{ct_n}| \geq \frac{r_n}{2} - 2t_n \right\}
\]
and
\[
\tilde{A}_k := \left\{ \sup_{0 \leq |s| \leq t_n} |\tilde{M}_{ct_n+s} - \tilde{M}_{ct_n}| \geq \frac{r_n}{2} - 2t_n \right\}.
\]
Let \( W \) be a Brownian motion defined on some probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \). By (5.6) we have
\[
Q^{(n)}(A_k) \leq 2 \mathbb{P}\left( \sup_{0 \leq s \leq t_n} |W_s| \geq \frac{r_n - 1 - 4t_n}{4\sqrt{\Theta_n}} \right) \leq C \frac{\sqrt{\Theta_n/t_n}}{r_n - 1 - 4t_n} \exp\left( -\frac{(r_n - 1 - 4t_n)^2}{32 \Theta_n t_n} \right)
\]
for some positive constant \( C \); the same identity holds for \( \tilde{A}_k \), using (5.6). Summing over \( k \) and using Inequality (5.5) yields the statement of the proposition since \( E_n \subset \bigcup_{k=1}^{\ell_n} (A_k \cup \tilde{A}_k) \).

This key proposition being proved, it becomes easy to prove theorem [13].

**Proof of Theorem [13]** – Taking \( R_n = 2^{n+5} \) and \( t_n \leq 2^{n+1} \) in Proposition [19] so that \( T_n \leq 2^n \), we get for any \( n \geq 1 \):
\[
(5.8) \quad \mathbb{P}_{B^{(1)}}(E_n) = \mathbb{P}_{B^{(1)}}(\tau_n - \tau_{n-1} \leq t_n, \tau_n \leq T_n) \leq C \frac{\text{Vol}(B^{(n)})}{\text{Vol}(B^{(1)})} \sqrt{\Theta_n/t_n} \exp\left( -\frac{4^n}{\Theta_n t_n} \right).
\]

Specifying the choice of \( t_n \) by setting
\[
t_n := \min \left\{ 2^{n+1}, \frac{4^{n-1}}{\left( 1 + \log^+ \left[ \frac{\hat{\Theta}_n \text{Vol}(B^{(n)})}{\Theta_n} \right] \right) \hat{\Theta}_n} \right\},
\]
the right hand side of (5.8) is seen to be bounded above by a constant multiple of \( 2^{-n} \), ensuring as a consequence the convergence of the series \( \sum_{n \geq 1} \mathbb{P}_{B^{(1)}}(E_n) \). Indeed, we get from (5.8), with the above \( t_n \),
\[
\mathbb{P}_{B^{(1)}}(E_n) \leq C' \text{Vol}(B^{(n)}) \sqrt{\hat{\Theta}_n^2 \log \left[ \frac{\hat{\Theta}_n \text{Vol}(B^{(n)})}{\Theta_n} \right] } e^{-4 \log \left[ \frac{\hat{\Theta}_n \text{Vol}(B^{(n)})}{\Theta_n} \right]} \leq C'/2^n.
\]
(Ignoring the trivial case \( \Theta \equiv 0 \), we can suppose without loss of generality that we have \( \hat{\Theta}_n \text{Vol}(B^{(n)}) \geq 3 \) for \( n \) large enough.) Note that the above choice of time increments \( t_n \) is simpler than Hsu and Qin’s choice in [HQ10]; there is in particular no need to introduce
their auxiliary function \( h(R) \equiv \log \log R \), to get Grigor’yan’s criterion, if the second upper bound of their section 3 is not used.

To conclude that the \( \Theta \)-diffusion does not explode we need to check that \( T_n = \sum_{k=1}^{n} t_k \) increases to infinity. For the above choice of time increments \( t_n \), we have \( \mathbb{P}_{B^{(1)}} \)-almost-surely, for \( n \) larger than some \( n_0 \), and for a positive universal constant \( c \):

\[
T_n \geq \sum_{k=n_0}^{n} \min \left\{ 2^{k+1}, \frac{4^{k-1}}{\Theta_{2^{k+5}+1} \log^{+}[\Theta_{2^{k+5}+1} \text{Vol}(B_{2^{k+5}})] + 1} \right\} \\
\geq c \int_{2^{n_0}+1}^{2^n} \min \left\{ 8, \frac{r}{\Theta_r \log \left[ \Theta_r \text{Vol}(B_r) \right]} \right\} dr.
\]

(5.9)

Leaving aside the trivial case \( \Theta \equiv 0 \) and recalling that the map \( r \mapsto \Theta_r = \max_{B_r} \Theta \) is non-decreasing, we can suppose without loss of generality that \( \Theta_r \geq 3 \). The divergence of the sequence \( (T_n) \) is then granted by the integral criterion

\[
\int_{0}^{\infty} \min \left\{ 8, \frac{r}{\Theta_r \log \left[ \Theta_r \text{Vol}(B_r) \right]} \right\} dr = \infty.
\]

As \( \Theta_r \) increases, this condition is equivalent to

\[
\sum_{n \geq 1} \min \left\{ 8, \frac{n}{\Theta_n \log \left[ \Theta_n \text{Vol}(B_n) \right]} \right\} = \infty,
\]

that is to

\[
\sum_{n \geq 1} \frac{n}{\Theta_n \log \left[ \Theta_n \text{Vol}(B_n) \right]} = \infty,
\]

since the former holds obviously if an infinite number of terms were larger than 8. The previous condition is equivalent to Condition (5.2) of Theorem 13.

Using Borel-Cantelli lemma under the form of Lemma 18 it follows that we have

\[
\mathbb{P}_{B^{(1)}} \left( \sup_{0 \leq s \leq T_n - \delta} \mathcal{D}(\Phi_s) \leq 2^{n+5} \text{ for any large enough } n \right) = 1,
\]

so \( \sup_{0 \leq s \leq t} \mathcal{D}(\Phi_s) < \infty \), for all \( t > 0 \), since \( T_n \) increases to \( \infty \). Would a realization of the path \( \Phi_s \) explode by time \( t \), its projection in \( \mathcal{M} \) would provide a timelike path with an accumulation point (for it stays in the projection of a compact set by hypothesis (H)), contradicting the strong causality assumption on \( \mathcal{M} \).

To prove that the same happens under any \( \mathbb{P}_\Phi \), notice that since the non-explosion event \( E \) belongs to the invariant \( \sigma \)-algebra, the function \( \Omega \mathcal{M} \ni \Phi \mapsto \mathbb{P}_\Phi(E) \) is \( \mathcal{G}_\Theta \)-harmonic, hence continuous, as \( \mathcal{G}_\Theta \) is hypoelliptic. It follows that since

\[
\mathbb{P}_{B^{(1)}}(E) = \frac{1}{\text{Vol}(B^{(1)})} \int_{B^{(1)}} \mathbb{P}_\Phi(E) \text{Vol}(d\Phi),
\]

the probability \( \mathbb{P}_\Phi(E) \) must be equal to 1 for all \( \Phi \in B^{(1)} \). But as the ball \( B^{(1)} \) was arbitrarily chosen, \( \mathbb{P}_\Phi(E) \) is identically equal to 1 everywhere. \( \square \)
5.5. Upper rate function. Using essentially the same reasoning as in Section 4 of \cite{HQ10}, the above proof yields almost for free the upper rate function for the $\Theta$-diffusion given in corollary\cite{Ib}. See also\cite{Gr1999} for related results. We keep the preceding notations.

**Proof of Corollary**\cite{Ib} – We follow the argument of \cite{HQ10}, Section 4, making sure that it works here as well with our choice for $t_n$, and without their auxiliary function $\log \log \cdot$. Suppose first $\Theta$ non-identically null and recall inequality (5.9), in which we can forget to take the minimum with $\delta$, by Proposition\ref{prop:20} below. By (5.10), this yields the almost-surely inequality
\[
\sup_{0 \leq s \leq c h^{-1}(2^n) - \delta} \mathcal{D}(\Phi_s) \leq 2^{n+5},
\]
that is
\[
\sup_{0 \leq s \leq c h^{-1}(R) - \delta} \mathcal{D}(\Phi_s) \leq 32 R,
\]
for large enough $R$. Letting $R = h((t + \delta)/c)$, this entails $\sup_{0 \leq s \leq t} \mathcal{D}(\Phi_s) \leq 32 h((t + \delta)/c)$, hence $\sup_{0 \leq s \leq t} \mathcal{D}(\Phi_s) \leq 32 h(C t)$, for large enough $t$. This shows the claim under the probability $\mathbb{P}_{\Phi_0}$, and then under $\mathbb{P}_{\Phi_k}$ as well, by the same argument already used at the end of the proof of Theorem\cite{Ib}. Finally, in the geodesic case ($\Theta \equiv 0$), the same holds with $T_n \geq c 2^n = c h(2^n)$.

5.6. Estimates of the volume of the sub-Riemannian boxes and application. Let us begin with a crude lower estimate of the volume of the boxes $B_r$ based on the vertical expansion in the $SO_0(1,d)$-fibre of $\mathcal{O}M$, without taking into account the horizontal expansion which depends on the curvature of the base Lorentzian manifold $M$. We used this lower bound in the proof of Corollary\cite{Ib}.

**Proposition**\ref{prop:20}. We have $\liminf_{r \to \infty} \frac{\log \text{Vol}(B_r)}{r} \geq d - 1$.

**Proof** – Fix a relatively compact neighbourhood $U$ of $m_0$ in $M$, above which $\mathcal{O}U$ is trivialized in $U \times SO_0(1,d)$. Assume without loss of generality that $\Phi_0$ corresponds to $(m_0, 1)$. By the ball-box theorem (see e.g. \cite{Mon02}), the box $B_r = \{ \mathcal{D} \leq r \}$ contains a neighbourhood $U \times B(1, \varepsilon)$ of $\Phi_0$, for some $\varepsilon > 0$ and for $r$ larger than some fixed $r_1$. Using this argument a finite number of times, together with the triangle inequality for $\mathcal{D}$, we see that the box $\{ \mathcal{D} \leq r \}$ contains any neighbourhood $U \times B(1, \varrho)$ of $\Phi_0$, for any $\varrho > 0$, provided $r$ is large enough, say no less than $r_0 = r_0(U, \varrho)$. Take $\varrho$ larger than the diameter of $SO(d)$.

We easily see that the boxes $\{ \mathcal{D} \leq r \}$ dilate in the vertical directions $V_1, \ldots, V_d$ with speed $r$, as $r$ increases. So $\{ \mathcal{D} \leq r \}$ contains the product of $U$ by the ball of radius $(r - r_0)$ in $SO_0(1,d)$ for $r$ large enough. This provides a lower bound on $\text{Vol}(\{ \mathcal{D} \leq r \})$ by some constant multiple of the volume of the hyperbolic ball of radius $(r - r_0)$, from which it follows that there exists some positive constant $c$ such that $\log \text{Vol}(B_r) \geq (d - 1) r + \log c$, for $r$ large enough.

To close this work, we give a non-explosion criterion involving only the geometry of $M$, rather than the geometry of $\mathcal{O}M$ as it appears in Theorem\cite{Ib} through the sub-Riemannian boxes $B_r$. 

\[\]
Proposition 21. Fix $\Phi_0 = (m_0, e_0) \in \mathcal{OM}$, and define the $S_{\Phi_0}$-radius $\rho^S_{\Phi_0}(m)$ of any $m \in \mathcal{M}$ as the infimum of the $S_{\Phi_0}$-length of $C^1$ paths joining $m_0$ to $m$. Define the $S_{\Phi_0}$-ball $B^S_{\Phi_0}(r)$ of radius $r$ as the set $B^S_{\Phi_0}(r) := \{ m \in \mathcal{M} \mid \rho^S_{\Phi_0}(m) \leq r \}$, and set $V^S(r) := \text{Vol}_\mathcal{M}(B^S_{\Phi_0}(r))$. Then there exists a constant $C$ such that for all $r > 0$ 
\[
\log \text{Vol}(B_r) \leq C + (d - 1) r + \log V^S(0^+),
\]
Note that the $S_{e_0}$-balls $B^S_{e_0}(r)$ and their volume depend only on the choice of $\Phi_0 = (m_0, e_0) \in \mathcal{OM}$ and on the geometry of $\mathcal{M}$. We noticed indeed in Section 4 that the $S_{e_0}$-length of a path in $\mathcal{M}$ started from $m_0$ is the Euclidean length of its anti-development in $(T_{m_0}\mathcal{M}, e_0)$.

Proof – By the definitions in Sections 4 and 5.1.1 the $b$-distance of $\Phi_0$ to any $\Phi \in \mathcal{OM}$ is larger than $D_{\Phi_0}(\Phi)$, so $B_r \subset B^b(\Phi_0; r)$, where $B^b$ denotes the ball in $\mathcal{OM}$ of the $b$-metric. Vertically, that is to say in the frame $\tau_{\Phi_0}(\Phi_0)$ parallelly transported along a minimizing curve $\gamma$, the maximal hyperbolic distance reached by the velocity component $\dot{m}_s$ of $\gamma_s$ is $s$, which is responsible for a maximal vertical volume $\mathcal{O}(e^{(d-1)r})$.

Having accelerated till reaching a maximal velocity $\mathcal{O}(e^r)$, a minimizing curve in $B^b(\Phi_0; r)$ can perform a maximal horizontal displacement $\mathcal{O}(e^r)$. Hence we have the inclusions $B^S_{\Phi_0}(r) \subset \pi_0(B^b(\Phi_0; r)) \subset B^S_{\Phi_0}(\mathcal{O}(e^r))$, and so $\text{Vol}(B_r) \leq C e^{(d-1)r} V^S(0^+)$. \(\blacksquare\)

Applying Proposition 21 to the integral condition of Theorem 13 yields in the case of a bounded $\Theta$ the non-explosion criterion $\int_0^\infty \frac{r \, dr}{r + \log V^S(e^r)} = \infty$. Using the increasing character of the map $(r \mapsto V^S(e^r))$, discretizing and distinguishing whether or not there are infinitely many $n$ such that $\log V^S(e^n) \leq n$, we easily see that this condition is equivalent to the condition $\int_0^\infty \frac{r \, dr}{\log V^S(e^r)} = \infty$.

Corollary 22. Let $(\mathcal{M}, g)$ be a strongly causal Lorentz manifold satisfying the completeness assumption (H) and the volume growth condition: $\int_0^\infty \frac{r \, dr}{\log V^S(e^r)} = \infty$. Then all $\Theta$-diffusions with a bounded $\Theta$ are stochastically complete.

It is easy to see that this volume growth integral criterion does not depend on the choice of $\Phi_0 \in \mathcal{OM}$. Contrary to Proposition 20, it relies on the horizontal expansion and not on the vertical expansion. This criterion does not apply to Gödel universe, for which $V^S(e^r)$ is of order $e^r$; the non-explosion criterion of 3.2 covers the case of that spacetime. Corollary 22 applies for example to Lorentz manifolds which are topologically $\mathbb{R}^{1+d}$ and have a pseudo-metric $g$ such that $g, g^{-1}$, and the first order derivatives of $g$ with respect to the canonical coordinates are bounded, since then $\log V^S(e^r)$ is of order $r$, as is the case in Minkowski spacetime.
