Differential graded motives: weight complex, weight filtrations and spectral sequences for realizations; Voevodsky vs. Hanamura

M.V. Bondarko *

October 29, 2018

Abstract

We describe explicitly the Voevodsky’s triangulated category of motives $DM^{\text{eff}}_{gm}$ (and describe a ‘differential graded enhancement’ for it). This enables us to able to verify that $DM_{gm}Q$ is (anti)isomorphic to Hanamura’s $\mathcal{D}(k)$.

We obtain a description of all subcategories (including those of Tate motives) and of all localizations of $DM^{\text{eff}}_{gm}$. We construct a conservative weight complex functor $t : DM^{\text{eff}}_{gm} \to K^b(CHow^{\text{eff}})$; $t$ induces an isomorphism $K_0(DM^{\text{eff}}_{gm}) \to K_0(CHow^{\text{eff}})$. A motif is mixed Tate if and only if its weight complex is. Over finite fields the Beilinson-Parshin conjecture holds iff $tQ$ is an equivalence.

For a realization $D$ of $DM^{\text{eff}}_{gm}$ we construct a spectral sequence $S$ (the spectral sequence of motivic descent) converging to the cohomology of an arbitrary motif $X$. $S$ is ‘motivically functorial’; it gives a canonical functorial weight filtration on the cohomology of $D(X)$. For the ‘standard’ realizations this filtration coincides with the usual one (up to a shift of indices). For the motivic cohomology this weight filtration is non-trivial and appears to be quite new.

We define the (rational) length of a motif $M$; modulo certain ‘standard’ conjectures this length coincides with the maximal length of the weight filtration of the singular cohomology of $M$.

MSC 2000: 14F42; 16E45; 14F20; 19D55; 32S20.

Keywords: motives, algebraic cycles, realizations and cohomology, weight filtrations and spectral sequences.

Introduction

We give an explicit description of the category of effective geometric motives of Voevodsky (see \cite{Voe00a}). In what follows $DM^s$ is the full triangulated subcategory of the category $DM_{gm}^{eff}$ (defined in \cite{Voe00a}) generated by motives of smooth varieties (we do not add the kernels of projectors). It is proved that for any motivic complex $M$ (i.e. an object of Voevodsky’s $DM_{gm}^{eff}$ that comes from $DM^s$; in particular, the Suslin complex of an arbitrary variety) there exists a quasi-isomorphic complex $M'$ constructed from the Suslin complexes of smooth projective varieties; $M'$ is unique up to a homotopy. We prove that Hanamura’s $\mathcal{D}(k)$ is (anti)equivalent to Voevodsky’s $DM_{gm}^{eff}$. 

\begin{itemize}
\item 6.5 Explicit calculation of $m^{-1}(M_{gm}^c(X))$; the weight complex of smooth quasi-projective varieties \hfill 44
\item 6.6 cdh-hypercoverings; the weight complex of Gillet and Soulé for arbitrary varieties \hfill 46
\item 7 Realizations of motives; weight filtration; the spectral sequence of motivic descent \hfill 48

\item 8.4 An application: independence on $l$ for traces of open correspondences \hfill 66
\item 8.5 Adding kernels of projectors to $J$ \hfill 67
\item 8.6 The functors $m_N$ \hfill 68
\end{itemize}
Our main category $\mathcal{H}$ is defined as the category of twisted complexes over a certain differential graded category whose objects are cubical Suslin complexes; we construct an equivalence $m : \mathcal{H} \to DM^s$. In terms of [BoK90] our description of $DM^s$ gives an enhancement of this category. One should think of twisted complexes as of the results of repetitive computation of cones of morphisms in an ‘enhanced’ triangulated category. One can describe any subcategory of $\mathcal{H}$ that is generated by a fixed set of objects; this method gives an integral description of the triangulated category of Tate motives similar to the rational description of [KrM95]. Besides, any localization of $\mathcal{H}$ can be described explicitly using the construction of Drinfeld (see [Dri04]).

As an application we consider the problem of constructing exact functors from $DM^s$ (i.e. realizations) in terms of cubical Suslin motivic complexes. The most simple and yet quite interesting of functors constructed by our method are the truncation functors $t_N$ that correspond to the canonical filtration of Suslin complexes. The target of $t_0$ is just the category $K^b(Corr_{rat})$ ($Corr_{rat}$ is ‘almost’ the category of effective Chow motives, see [1.1]). $t_0$ extends to conservative weight complex functors $t : DM^{eff}_{gm} \to K^b(Chow^{eff})$ and $t_{gm} : DM_{gm} \to K^b(Chow)$. We prove that $t$ induces an isomorphism $K_0(DM^{eff}_{gm}) \to K_0(Chow^{eff})$ thus answering a question from [GiS96].

We show that if $W$ denotes the weight filtration on $H^i(X)$ for a ‘standard’ realization $H$ then $W_{l+N}H^i(X)/W_{l-1}H^i(X)$ factors through $t_N$.

We prove that a motif $X$ belongs to a triangulated category $M \subset \mathcal{H}$ generated by motives of a given set of smooth projective varieties $P_i$, if and only if the same is true for $t(X)$ (as a complex of Chow motives). In particular, the motif of a smooth variety is a mixed Tate one iff its weight complex (as defined by Gillet and Soulé) is.

For any realization $D$ of motives that belongs to a wide class of ‘enhanceable’ realizations (i.e. of realizations that admit a differential graded ‘enhancement’) we construct a family of ‘truncated realizations’. In particular, this result can be applied to ‘standard’ realizations and motivic cohomology; an interesting new family of realizations is obtained. This yields a canonical spectral sequence $S$ converging to the cohomology of $D(X)$ of an arbitrary motif $X$. $S$ could be called the spectral sequence of motivic descent. The $E_1$-terms of $S$ are expressed in cohomology of smooth projective varieties, the $E_n$-terms of $S$ have a nice description in terms of $t_{2n-2}(X)$, $n \geq 1$. $S$ is canonical and ‘motivically functorial’, it is also functorial with respect to transformations of functors. $S$ gives a canonical non-trivial weight filtration for ‘differential graded’ realizations of motives; for the ‘standard’ realizations this filtration coincides with the usual one (up to a shift of indices).

The simplest case of $S$ for motivic cohomology is the Bloch’s long exact localization sequence for higher Chow groups (see [Blo94]). Our ‘weight’
filtration on motivic cohomology is non-trivial and was not mentioned in the literature; it gives a new filtration on the $K$-theory of a smooth variety $X$.

We also study motives with compact support ($M_{gm}$ in the notation of Voevodsky). We give an explicit description of $M_{gm}$ for a variety $Z$ and prove that the weight complex of Gillet and Soulé can be described as $t_0(m^{-1}(M_{gm}(Z)))$ (with reversed arrows); the functor $h$ of Guillen and Navarro Aznar is (essentially) $t_0(m^{-1}(M_{gm}(Z)))$.

We define the 'length' of a motif (stupid, fine or rational); this is a natural motivic analogue of the length of weight filtration for a mixed Hodge structure. For a smooth variety $X$ the length of $M_{gm}(X)$ lies between the length of the weight filtration of the singular cohomology of $X$ and the dimension of $X$. If certain 'standard' conjectures are valid then the rational length of a motif coincides with the (appropriately defined) length of the weight filtration of its singular realization.

We note that in the current paper we apply several results of [Voe00a] that use resolution of singularities; yet applying de Jong’s alterations one can easily extend (most of) our results (at least) to motives with rational coefficients over an arbitrary perfect $k$. For a finite $k$ the Beilinson-Parshin conjecture (that the only non-zero $H^i(X, \mathbb{Q}(n))$ for smooth projective $X$ is $H^{2n}$) holds iff $t\mathbb{Q} : DM_{gm}^{eff,\mathbb{Q}} \to K^b(CHow^{eff,\mathbb{Q}})$ is an equivalence (note that here $DM_{gm}^{eff,\mathbb{Q}}$ and $t\mathbb{Q}$ denote the appropriate idempotent completions). Much can also be proved with integral coefficients.

The author would like to note that several interesting results of this paper (in particular, the properties of $t_0$ and $t$) follow just from the fact that $J = Tr(J)$ for $J$ being a negative differential graded category (see subsection 2.4). Hence these results are also valid for any other example of this situation. Moreover, in [Bon10] a set of axioms of so-called weight structures for a triangulated category $C$ is introduced (see Remark 7.4.4). This (abstract) approach allows extending (most of) the results of the current paper to a wide class of triangulated categories and realizations that do not necessarily have a differential graded 'enhancement'; in particular, it can be applied to the stable homotopy category (of spectra). The definition of the weight filtration (and spectral sequences) for realizations is quite easy in this context. This formalism is also closely (and nicely) related to $t$-structures. Yet in this abstract setting it is difficult to define truncation functors (especially the 'higher' ones).

Besides, recently Levine (in his very interesting paper [Lev09]) extended some of the results of the current paper to relative motives (i.e. motives over a regular base $S$, which is essentially of finite type over $k$). This paper also contains a nice exposition of the yoga of cubical objects (which is essential for the current paper) and of related tensor products.
Now we list the contents of the paper. More details can be found in the beginnings of sections.

In the first section we recall some basic notation of [Voe00a] (with minor modifications). Next we describe cubical Suslin complexes and their properties. Most of the proofs are postponed till §5 since they are not important for the understanding of main results.

We start §2 by recalling the formalism of differential graded categories (2.1) and twisted complexes (2.2 and 2.3). Next we use this formalism to construct our main objects of study: a triangulated category \( \mathcal{H} \) and a functor \( h \) from \( \mathcal{H} \) into the homotopy category of complexes of Nisnevich sheaves with transfers (2.4). \( \mathcal{H} \) as a triangulated category is generated by motives of smooth projective varieties. We also describe \( \mathcal{H} \) and \( h \) more explicitly (in 2.5). We define 'stupid' filtration for objects of \( \mathcal{H} \) that is similar to the 'stupid' filtration for complexes over an additive category (2.6). Note that (similarly to the case of complexes) the filtration for a motif also depends on the choice of its 'lift' to a certain differential graded category (as the stupid truncation object of \( K(A) \) depends on its lift to \( C(A) \)); yet this filtration is 'functorial enough' for our purposes. In 2.7 we introduce more differential graded definitions; they will be used in section 7.

In §3 we prove (Theorem 3.1.1) that \( h \) composed with the natural functor from the homotopy category of sheaves with transfers to the derived category gives an equivalence \( m : \mathcal{H} \to DM^s \). Lastly we give a certain differential graded description of Voevodsky’s \( DM_{gm}^Q \); to this end we define \( \otimes \mathbb{Z}(1) \) on \( \mathcal{H} \) and formally invert this functor.

In §4 we prove that Voevodsky’s \( DM_{gm}^Q \) is (anti)isomorphic to Hanamura’s \( D(k) \).

In §5 we verify the properties of cubical Suslin complexes. The reader not interested in the proofs of auxiliary results of §1 may skip this section.

In §6 using the canonical filtration of the (cubical) Suslin complex we define the ‘truncation’ functors \( t_N : \mathcal{H} \to \mathcal{H}_N \) (in 6.1). \( \mathcal{H}_0 \) (i.e. the target of \( t_0 \)) is just \( K^b(Corr_{rat}) \). These functors are new though their certain restrictions to varieties were (essentially) considered in [GiS96] and [GN-A02] (and were shown to be quite important). We prove that \( t_0 \) extends to \( t : DM_{gm}^{eff} \to K^b(Chow^{eff}) \) and \( t_{gm} : DM_{gm} \to K^b(Chow) \) (in 6.3). All \( t_N \) (see Theorem 6.2.1), \( t \) (Proposition 6.3.1), and \( t_{gm} \) (Remark 6.3.2) are conservative. \( t \) induces an isomorphism \( K_0(DM_{gm}^{eff}) \cong K_0(Chow^{eff}) \) (Theorem 6.4.2); \( t_{gm} \) gives \( K_0(DM_{gm}) \cong K_0(Chow) \). Certainly, this extends to an isomorphism \( K_0(DM_{gm}) \cong K_0(Chow) \) (Corollary 6.4.3).

We define the length of a motif (three types); the stupid length (see 6.2) is not less than the fine one (see 6.3), which is not less than the rational length. We prove that motives of smooth varieties of dimension \( N \) have stupid length
≤ N (parts 1 and 2 of Theorem 6.2.1); besides \( t_N(X) \) contains all information on motives of stupid length ≤ N (see part 3 of Theorem 6.2.1 and 7.3).

At the end of the section we calculate \( m^{-1}(\mathcal{M}_{gm}(X)) \) for a smooth \( X \) explicitly (in 6.5). Using this result as well as cdh-descent we prove that the weight complex of Gillet and Soulé for \( X/k \) can be described as \( t_0(m^{-1}(\mathcal{M}_{gm}(X))) \) (with arrows reversed; see 6.6). Besides, \( t_0(m^{-1}(\mathcal{M}_{gm}(X))) \) essentially coincides with the functor \( h \) described in Theorem 5.10 of [GN-A02].

In §7 we study realizations of the category of motives and their connections with (certain) weight filtrations. The differential graded categories formalism yields a general recipe of constructing realizations (see 7.1). It is quite easy to determine which of those enhanceable realizations can be factored through \( t_N \).

We verify that the étale and motivic cohomology are enhanceable realization (see 7.2, 7.3, and part 1 of Remark 7.3.1). Very probably, this result could be extended to all other 'standard' realizations. In 7.3 for any enhanceable realization \( D \) we describe an interesting new family of 'truncated realizations'; they correspond to 'forgetting' cohomology outside a given range of weights. Truncated realizations give a filtration of the complex that computes the given 'enhanced' realization of a motif \( Y \). We obtain a spectral sequence \( S \) converging to \( D^l(Y) \) (see (14)). Its \( E_n \)-terms for \( n \geq 2 \) have a nice description in terms of \( t_{2n-2}(Y) \); in particular, \( E_1 \)-terms are functorial in \( t_0(Y) \). \( S \) is the spectral sequence of motivic descent. \( S \) gives a canonical integral weight filtration for 'enhanced' realizations of motives; for the 'standard' realizations this filtration coincides with the usual one (up to a shift of indices). \( S \) is 'motivically functorial', it is also functorial with respect to ('enhanced') transformation of functors.

In §7.4 we prove that for a 'standard' \( H \) the \( N \)-th truncated realization computes \( W_{l+N}H^l(X)/W_{l-1}H^l(X) \), while \( W \) equals the 'standard' weight filtration. A morphism \( f \) induces a zero morphism on cohomology if \( t_0(f) \) is zero. We also prove (modulo certain 'standard' conjectures) that the rational length of a motif coincides with the 'range' of difference of \( l \) with the weights of \( H^l \) for all \( l \); see Proposition 7.4.2. We conclude the section with a discussion of \( qfh \)-descent and motives of singular varieties (see 7.5).

In section 8 we apply the general theory of [BoK90] to describe any subcategory of \( \mathcal{H} \) that is generated by a fixed set of objects (see 8.1). In particular, this method can be used to obtain an integral description of the triangulated category of effective Tate motives (i.e. the full triangulated subcategory of \( \mathcal{H} \) generated by \( \mathbb{Z}(n) \) for \( n > 0 \)).

In 8.2 we describe the construction of 'localization of differential graded categories' (due to Drinfeld). This gives us a description of localizations of \( \mathcal{H} \). As an application, we prove that the motif of a smooth \( X/k \) is a mixed
Tate one if and only if the weight complex of $X$ (defined in [GiS96]) is.

In §3 we verify that over an arbitrary perfect field one can apply our theory (at least) with rational coefficients. Moreover, over finite fields the Beilinson-Parshin conjecture holds iff $tQ : DM_{gm}^{eff} \rightarrow K^b(\text{Chow}^{eff}Q)$ is an equivalence. We also describe an idea for constructing a certain 'infinite integral' weight complex functor in finite characteristic.

In §4 we prove that traces of endomorphisms of cohomology of motives induced by endomorphisms of motives do not depend on the choice of a Weil cohomology theory. In particular, this statement can be applied for the morphisms induced by 'open correspondences' (as described in Definition 3.1 of [BlE07]). We obtain a generalization of Theorem 3.3. of loc. cit. to the case of varieties which are not necessarily complements of smooth projective varieties by strict normal crossing divisors.

In §5 we note that one can modify the description of $DM^s$ so that $Z(n)$ will have stupid length 0. Lastly we describe certain functors $m_N : \mathfrak{h}_N \rightarrow DM^{eff}_s$ (see §6). $t_N$ and $m_N$ could be related to the (yet conjectural) weight filtration on $DM_{gm}^{eff}$.

The author is deeply grateful to prof. B. Kahn, Dr. F. Deglise, prof. A. Suslin, prof. M. Spiess, and to Dr. N. Dourov for very useful comments. The author is also deeply indebted to the officers and guests of Max Planck Institut (Bonn) and of IHES (Paris) for excellent working conditions during his stays in these places.

**Notation.** In this paper all complexes will be cohomological i.e. the degree of all differentials is +1.

We recall that for any triangulated $T$ there exists a unique category $T' \supset T$ that is obtained from $T$ by 'adding the kernels of all projectors'; $T'$ is called the idempotent completion of $T$ (see [BaS01]).

For an additive category $A$ we will denote by $A \otimes Q$ its rational hull i.e. $ObjA \otimes Q = Obj A$ while morphisms are tensored by $Q$. $AQ$ will usually (except for some notation of §4) denote the idempotent completion of $A \otimes Q$.

We will call a realization of motives (usually of $\mathfrak{h}$) enhanceable if it has a differential graded enhancement, see §7.

Other notation will be more or less standard. $k$ will denote the ground field; we will assume (except in subsection §3.3) that the characteristic of $k$ is zero. $pt$ is a point, $A^n$ is the $n$-dimensional affine space (over $k$), $\mathbb{P}^n$ is the projective space of dimension $n$.

For an additive category $A$ we denote by $C^-(A)$ the category of complexes over $A$ bounded from above; $C^b(A) \subset C^-(A)$ is the subcategory of bounded complexes; $K^-(A)$ is the homotopy category of $C^-(A)$ i.e. the morphisms of complexes are considered up to homotopy equivalence; $K^b$ denotes the
homotopic category of bounded complexes; sometimes we will also need the unbounded categories $C(A)$ and $K(A)$; $Ab$ is the category of abelian groups.

For a category $C$, $A, B \in \text{Obj} C$, we denote by $C(A, B)$ the set of $C$-morphisms from $A$ to $B$.

For categories $C, D$ we write $C \subset D$ if $C$ is a full subcategory of $D$.

We list the main definitions of this paper. Some basic motivic definitions (mostly coming from [Voe00a]) will be given in 1.1. $C(X)$ will be defined in 1.2; $g^I$ will be defined in 1.3; differential graded categories, $H(C)$ for a differential graded category $C$, $S(A), S_N(A), B^-(A), B^b(A), B(A), C(A)$ for an additive category $A$ will be defined in 2.1; the categories of twisted complexes (Pre-Tr$(C)$, Tr$(C)$, Pre-Tr$^+(C)$, Tr$^+(C)$), arrows, $[P]$ and $P[i]$ for $P \in \text{Obj} C$ will be defined in 2.2 and 2.3; Tr$(F)$, Pre-Tr$(F)$, Tr$^+(F)$, and Pre-Tr$^+(F)$ for a differential graded functor $F$ will be defined in Remark 2.3.3; $J, \delta$, and $h$ will be defined in 2.4; $J', h', j$, and $J'$ will be defined in 2.5; $C_-$ and different types of truncations of complexes ($\tau_{\leq b}$, $\tau_{[a,b]}$, and the canonical $[a,b]$-truncation) will be defined in 2.6; $m$ will be defined in 2.7; $DM_{gm}$ will be described in 3.1; $C_N(P)$, $\delta_N$, and $t_N$ will be defined in 6.1; $t_Q$, and $DM_{gm}^{eff} \cong DM_{gm}^{eff}$ will be defined in 6.2; truncated realizations will be defined in 7.3.

1 Cubical Suslin complexes

In this paper instead of the simplicial Suslin complex $C(L(P))$ we consider its cubical version $C(P)$. In this section we prepare for the proof of the following fact: there exists a differential graded category $J$ (it will be defined in §2) whose objects are the (cubical) Suslin complexes of smooth projective varieties, while its morphisms are related to the morphisms between those complexes in $DM_{gm}^{eff}$.

First we recall basic definitions of Voevodsky (along with some ’classical’ motivic definitions).

1.1 Some definitions of Voevodsky: a reminder

We use much of the notation from [Voe00a]. We recall (some of) it here for the convenience of the reader. Those who remember Voevodsky’s notation well (and agree to identify certain equivalent categories) could skip this subsection; note only that $DM^s$ is the smallest strict triangulated subcategory of $DM_{gm}^{eff}$ containing all motives of smooth varieties.

$Var \supset SmVar \supset SmPrVar$ will denote the class of all varieties over $k$, resp. of smooth varieties, resp. of smooth projective varieties.
SmCor is the category of 'smooth correspondences' i.e. $\text{Obj}_{\text{SmCor}} = \text{SmVar}$, $\text{SmCor}(X, Y) = \bigoplus U \mathbb{Z}$ for all integral closed $U \subset X \times Y$ that are finite over $X$ and surjective over a connected component of $X$.

$\text{Shv}(\text{SmCor}) = \text{Shv}(\text{SmCor})_{\text{Nis}}$ is the abelian category of additive co-functors $\text{SmCor} \to \text{Ab}$ that are sheaves in the Nisnevich topology (when restricted to the category of smooth varieties); these sheaves are usually called 'sheaves with transfers'. Moreover, by default all sheaves will be sheaves in Nisnevich topology. By an abuse of notation we will also denote by $\text{Shv}(\text{SmCor})$ the set of all Nisnevich sheaves with transfers; $D^{-}(\text{Shv}(\text{SmCor}))$ is the bounded above derived category of $\text{Shv}(\text{SmCor})$.

For $Y \in \text{SmVar}$ (more generally, for $Y \in \text{Var}$, see §4.1 of [Voe00a]) we consider $L(Y) = \text{SmCor}(\cdot, Y) \in \text{Shv}(\text{SmCor})$. For $X \in \text{SmVar}$ we denote by $L^{c}(X)(Y) \supset L(X)(Y)$ the group whose generators are the same as for $L(X, Y)$ except that $U$ is only required to be quasi-finite over $X$. $L(X) = L^{c}(X)$ for proper $X$. Note that $L^{c}(X)$ is also a sheaf.

$M_{gm}(X) = \mathbb{C}(L(X)) \cong \mathbb{C}(L(X))$ is the Suslin complex of $L(X)$, see subsection 1.2 below for details; $M^{*}_{gm}(X) = \mathbb{C}(L^{c}(X)) \cong \mathbb{C}(L^{c}(X))$.

$S \in \text{Shv}(\text{SmCor})$ is called homotopy invariant if for any $X \in \text{SmVar}$ the projection $\mathbb{A}^{1} \times X \to X$ gives an isomorphism $S(X) \to S(\mathbb{A}^{1} \times X)$.

$DM^{-,eff} \subset D^{-}(\text{Shv}(\text{SmCor}))$ is the subcategory of complexes whose cohomology sheaves are homotopy invariant. It was proved in [Voe00a] that for any $F \in \text{Shv}(\text{SmCor})$ we have $\mathbb{C}(F) \in DM^{-,eff}$.

The functor $RC : D^{-}(\text{Shv}(\text{SmCor})) \to DM^{-,eff}$ is given by taking total complexes of the Suslin bicomplex of a complex of sheaves, see §3.2 of [Voe00a] for details.

$DM^{s}$ will denote the full strict triangulated subcategory of $DM^{-,eff}$ generated by $M_{gm}(X)$ for $X \in \text{SmVar}$ (we do not add the kernels of projectors).

$DM^{s}$ has a natural tensor structure that can be defined using the relation $M_{gm}(X) \otimes M_{gm}(Y) = M_{gm}(X \times Y)$; tensor multiplication of morphisms is defined by means of a similar relation.

In [Voe00a] Voevodsky defined $DM^{s}$ as a certain localization of $K^{b}(\text{SmCor})$ (note that he didn’t introduce any notation for $DM^{s}$; then $DM_{gm}^{-,eff}$ was defined as the idempotent completion of $DM^{s}$. Yet Theorem 3.2.6 of [Voe00a] (essentially) states that 'his' $DM^{s}$ is equivalent to those defined here. So we will denote by $DM_{gm}^{-,eff}$ (the idempotent completion of 'our' $DM^{s}$.

By definition (cf. subsection 2.1 in [Voe00a]) the Tate motif $\mathbb{Z}(1)[2] \in DM_{gm}^{-,eff}$ can be represented as the cone of the natural map $M_{gm}(\text{pt}) \to M_{gm}(\mathbb{P}^{1})$. Note also that $M_{gm}(\text{pt})$ is a direct summand of $M_{gm}(\mathbb{P}^{1})$, so $\mathbb{Z}(1)[2]$ also is. In particular, $\mathbb{Z}(1)[2]$ is also a Chow motive; see below.

$DM_{gm}$ in [Voe00a] was obtained from $DM_{gm}^{-,eff}$ (considered as an abstract
category i.e. not as a subcategory of $DM_{eff}^c$) by the formal inversion of $\mathbb{Z}(1)$ with respect to $\otimes$. We will use the same definition; see §3.3 below for details. $DM_{gm}$ is a rigid tensor triangulated category. We will also consider the idempotent completion $DM_{gm} \otimes \mathbb{Q}$ of $DM_{gm} \otimes \mathbb{Q}$.

$Corr_{rat}$ will denote the (homological) category of rational correspondences. Its objects are smooth projective varieties; the morphisms are morphisms in $SmCor$ up to homotopy equivalence. The category $Chow_{eff}$ is the idempotent completion of $Corr_{rat}$; it was shown in Proposition 2.1.4 of [Voe00a] that $Chow_{eff}$ is naturally isomorphic to the usual category of effective homological Chow motives.

$Chow$ will denote the whole category of Chow motives i.e. $Chow_{eff}[\mathbb{Z}(−1)[−2]]$. Note that the Chow motif that we denote by $\mathbb{Z}(1)[2]$ (this is compatible with the embedding $Chow_{eff} \to DM_{gm}^c$) was sometimes (‘classically’) denoted by $\mathbb{Z}(1)$; a similar convention was used by Hanamura. We will not pay much attention to this distinction below.

Note (as it is well known already from the works on Tate motives that come from quadratic forms) that $Obj_{Chow_{eff}} \neq Obj_{Chow_{eff} \otimes \mathbb{Q}}$ i.e. on the rational level one gets more idempotents in $Corr_{rat}$. Certainly, the same is true for $DM_{gm}^c$ and $DM_{gm}^c \otimes \mathbb{Q}$.

We recall also that for categories of geometric origin (for example, for $Corr_{rat}$ and $SmCor$) the addition of objects is induced by the disjoint union of varieties operation.

### 1.2 The definition of the cubical complex

For any $P \in SmVar$ we consider the sheaves

$$C^n(P)(Y) = SmCor(\mathbb{A}^{-i} \times Y, P), \ Y \in SmVar; \ C^i = 0 \text{ for } i > 0.$$  

We will usually consider projective $P$.

By Yoneda’s lemma

$$C^n(P)(Y) \cong Shv(SmCor)(L(Y), L(P)) = Shv(SmCor)(C^0(Y), C^n(P)).$$

For all $1 \leq j \leq -i$, $x \in k$, we define $d_{ijx} = d_{jx} : C^n \to C^{n+1}$ as $d_{jx}(f) = f \circ g_{jx}$, where $g_{jx} : \mathbb{A}^{-i-1} \times Y \to \mathbb{A}^{-i} \times Y$ is induced by the map $(x_1, \ldots, x_{-1-i}) \to (x_1, \ldots, x_j-1, x, x_j, \ldots, x_{-1-i})$. We define $C^i(P)(Y)$ as $\cap_{1 \leq j \leq -i} \text{Ker } d_{j0}$. One may say that $C^i(P)(Y)$ consists of correspondences that ‘are zero if one of the coordinates is zero’. The boundary maps $\delta^i : C^i \to C^{i+1}$ are defined as $\sum_{1 \leq j \leq -i} (-1)^j d_{j1}$. Again, $C^i = 0$ for positive $i$.

Since $C^0 = C^0$, we have $C^i(P)(Y) \cong Shv(SmCor)(C^0(Y), C^i(P))$. 

11
Remark 1.2.1. 1. The definition of the cubical Suslin complex can be easily extended to an arbitrary complex $D$ over $Shv(SmCor)$ (or over a slightly different abelian category). One should consider the total complex of the double complex whose terms are

$$D^{ij}(X) = \cap_{1 \leq l \leq i} \ker g_{j0}^*: D^j(\mathbb{A}^{-1} \times X) \to D^j(\mathbb{A}^{-i-1} \times X),$$

the boundaries are induced by $\delta^i$.

2. In the usual (simplicial) Suslin complex one defines $C^i(F)(X) = F(D^{-i} \times X)$, where $D^{-i} \subset \mathbb{A}^{1-i}$ is given by $\sum_{1 \leq i \leq i-1} x_i = 1$; the boundaries come from restrictions to $x_i = 0$.

It is well known that cubical and simplicial complexes do not differ much; the main advantage of cubical complexes is that descriptions of (various) products become much nicer (see §2.5 of [Lev05]).

We formulate the main property of $C$.

**Proposition 1.2.2.** For any $j \in \mathbb{Z}$, $Y \in SmVar$, and $P \in SmPrVar$ there is a natural isomorphism $H^jC(P)(Y) \cong A_{0,-j}(Y, P) \cong DM^{-j}_{eff}(C(Y), C(P)[j])$.

**Proof.** $A_{0,-j}(Y, P) \cong DM^{-j}_{eff}(C(Y), C(P))$ by Proposition 4.2.3 [Voe00a]. Since $P$ is projective, by Proposition 4.1.5 [Voe00a] we have $C^n(P) = C(P)$.

The first isomorphism will be described in §5 below.

All these isomorphisms are natural. \qed

In particular the cohomology presheaves of $C(P)$ are homotopy invariant.

We denote the initial object of $SmCor$ by $0$. We define $C^i(0) = 0$ for all $i \in \mathbb{Z}$. We obtain

$$p(C(P)) \in ObjDM^{-j}_{eff} \subset ObjD^-(Shv(SmCor)),$$

where $p: K^-(Shv(SmCor)) \to D^-(Shv(SmCor))$ is the natural projection.

### 1.3 The assignment $g \to (g^l)$

Let $P, Y$ belong to $SmVar$. We construct a family of morphisms $C(Y) \to C(P)[i]$.

For any $f \in C^0(P)(Y)$, $l \leq 0$, we define $f^l: C^l(Y) \to C^{l+i}(P)$ as follows. To the element $h \in SmCor(Z \times \mathbb{A}^{-l}, Y)$, $Z \in SmVar$, we assign $(-1)^lf \circ (id_{\mathbb{A}^{k-i}} \otimes h)$. It is easily seen that the same formula also defines the maps $f^l: C^l(Y) \to C^{l+i}(P)$ for $f \in C^l(P)(Y)$.

**Proposition 1.3.1.** 1. The assignment $g \to G = (g^l)$ defines a homomorphism $\ker \delta^i(P)(Y) \to K^-(Shv(SmCor))(C(Y), C(P)[i])$.

2. The assignment $g \to G = (g^l)$ induces an isomorphism $H^i(C(P)(Y)) \cong DM^{-j}_{eff}(C(Y), C(P)[i])$. 

12
Proof. 1. For any \( f \in C^n(P)(Y), h \in C^l(Y)(Z), Z \in \text{SmVar} \) we have an equality
\[
\delta^{i+l}f^1(h) = (-1)^i f^{l+1} \delta^i(h) + (\delta^i f)^1(h).
\] (1)
Hence if \( \delta^i g = 0, g \in C^i(P)(Y) \) then \( G \) defines a morphism of complexes \( C(Y) \to C(P)[i] \).

2. Using (1) we obtain that the elements of \( \delta^{i+1}(C^{i+1}(P)(Y)) \) give homomorphisms \( C(Y) \to C(P)[i] \) that are homotopy equivalent to 0. Hence we obtain a homomorphism \( H^iC(P)(Y) \to DM^\text{eff}(p(C(Y)), p(C(P)[i])) \). The bijectivity of this homomorphism will be proved in §5 below.

2 Differential graded categories; the description of \( J \) and \( h : J \to K^-(\text{Shv}(\text{SmCor})) \)

Categories of twisted complexes (defined in subsections 2.2 and 2.3) were first considered in [BoK90]. Yet our notation differs slightly from that of [BoK90]; some of the signs are also different.

In subsections 2.4 and 2.5 we define and describe our main categories: \( J, J', h \), and \( J' \).

In subsection 2.6 we define a natural 'stupid' filtration on \( J' \) that is 'close' to those on \( C^b(\text{Corr}_{\text{rat}}) \); we prove its natural properties.

We will not need the formalism of §2.7 till §7.

2.1 The definition of differential graded categories

Recall that an additive category \( C \) is called graded if for any \( P, Q \in \text{Obj}C \) there is a canonical decomposition \( C(P, Q) \cong \oplus_i C^i(P, Q) \) defined; this decomposition satisfies \( C^i(\ast, \ast) \circ C^j(\ast, \ast) \subset C^{i+j}(\ast, \ast) \). A differential graded category (cf. [BoK90] or [Dri04]) is a graded category endowed with an additive operator \( \delta : C^i(P, Q) \to C^{i+1}(P, Q) \) for all \( i \in \mathbb{Z}, P, Q \in \text{Obj}C \). \( \delta \) should satisfy the equalities \( \delta^2 = 0 \) (so \( C(P, Q) \) is a complex of abelian groups); \( \delta(f \circ g) = \delta f \circ g + (-1)^i f \circ \delta g \) for any \( P, Q, R \in \text{Obj}C \), \( g \in C^i(P, Q), f \in C^j(Q, R) \). In particular, \( \delta(id_P) = 0 \).

We denote \( \delta \) restricted to morphisms of degree \( i \) by \( \delta^i \).

For an additive category \( A \) one can construct the following differential graded categories. The notation introduced below will be used throughout the paper.

We denote the first one by \( S(A) \). We set \( \text{Obj}S(A) = \text{Obj}A; S(A)^i(P, Q) = A(P, Q) \) for \( i = 0 \); \( S(A)^i(P, Q) = 0 \) for \( i \neq 0 \). We take \( \delta = 0 \).
We also consider the category $B^-(A)$ whose objects are the same as for $C^-(A)$, whereas for $P = (P^i)$, $Q = (Q^j)$ we define $B^-(A)^i(P, Q) = \prod_{j \in \mathbb{Z}} A(P^j, Q^{i+j})$. Obviously $B^-(A)$ is a graded category.

We denote by $B^b(A)$ the full subcategory of $B^-(A)$ whose objects are bounded complexes. $B(A)$ and $C(A)$ will denote the corresponding categories whose objects are unbounded complexes.

We set $\delta f = d_Q \circ f - (-1)^i f \circ d_P$, where $f \in B^i(P, Q)$, $d_P$ and $d_Q$ are the differentials in $P$ and $Q$. Note that the kernel of $\delta^0(P, Q)$ coincides with $C(A)(P, Q)$ (the morphisms of complexes); the image of $\delta^{-1}$ are the morphisms homotopic to $0$.

For any $N \geq 0$ one can define a full subcategory $S_N(A)$ of $B^b(A)$ whose objects are complexes concentrated in degrees $[0, N]$. We have $S(A) = S_0(A)$. $B^b(A)$ can be obtained from $S(A)$ (or any $S_N(A)$) by means of the category functor $Pre-Tr$ described below.

For any differential graded $C$ we define a category $H(C)$; its objects are the same as for $C$; its morphisms are defined as

$$H(C)(P, Q) = \ker \delta^0_C(P, Q)/ \text{Im} \delta^{-1}_C(P, Q).$$

### 2.2 Categories of twisted complexes ($Pre-Tr(C)$ and $Tr(C)$)

Having a differential graded category $C$ one can construct two other differential graded categories $Pre-Tr(C)$ and $Pre-Tr^+(C)$ as well as triangulated categories $Tr(C)$ and $Tr^+(C)$. The simplest example of these constructions is $Pre-Tr(S(A)) = B^b(A)$.

**Definition 2.2.1.** 1. The objects of $Pre-Tr(C)$ are

$$\{(P^i), P^i \in \text{Obj}C, i \in \mathbb{Z}, q_{ij} \in C^{i-j+1}(P^i, P^j)\};$$

here almost all $P^i$ are $0$; for any $i, j \in \mathbb{Z}$ we have $\delta q_{ij} + \sum_{l} q_{ij} \circ q_{il} = 0$. We call $q_{ij}$ arrows of degree $i - j + 1$. For $P = \{(P^i), q_{ij}\}, P' = \{(P'^i), q'_{ij}\}$ we set

$$Pre-Tr(C)^1(P, P') = \bigoplus_{i, j \in \mathbb{Z}} C^{l+i-j}(P^i, P'^j).$$

For $f \in C^{l+i-j}(P^i, P'^j)$ (an arrow of degree $l + i - j$) we define the differential of the corresponding morphism in $Pre-Tr(C)$ as

$$\delta_{Pre-Tr(C)} f = \delta_C f + \sum_{m} (q'_{jm} \circ f - (-1)^{(i-m)} f \circ q_{mi}).$$

2. $Tr(C) = H(Pre-Tr(C))$. 

14
It can be easily seen that Pre-Tr($\mathcal{C}$) is a differential graded category (see [BoK90]). There is also an obvious translation functor on Pre-Tr($\mathcal{C}$). Note also that the terms of the complex Pre-Tr($\mathcal{C}$)($P, P'$) do not depend on $q_{ij}$ and $q'_{ij}$, whereas the differentials certainly do.

We denote by $Q[j]$ the object of Pre-Tr($\mathcal{C}$) that is obtained by putting $P_i = Q$ for $i = -j$, all other $P^j = 0$, all $q_{ij} = 0$. We will write $[Q]$ instead of $Q[0]$ (i.e., $Q[i]$ is the translation of $[Q]$ by $[i]$).

Immediately from definition we have Pre-Tr($\mathcal{S}(\mathcal{A})$) $\cong B^b(\mathcal{A})$.

A morphism $h \in \text{Ker} \delta_0$ (a closed morphism of degree 0) is called a twisted morphism. For a twisted morphism $h = (h_{ij}) \in \text{Pre-Tr}((P^i, q_{ij}), (P''^i, q''_{ij}))$, $h_{ij} \in C(P^i, P'^i)$ we define $\text{Cone}(h) = (P''^i, q''_{ij})$, where $P''^i = P^{i+1} \oplus P'^i$,

$$q''_{ij} = \begin{pmatrix} q_{i+1,j+1} & 0 \\ h_{i+1,j} & q'_{ij} \end{pmatrix}$$

We have a natural triangle of twisted morphisms

$$P \xrightarrow{f} P' \to \text{Cone}(f) \to P[1],$$

the components of the second map are $(0, \text{id}_{P'})$ for $i = j$ and 0 otherwise. This triangle induces a triangle in the category $H(\text{Pre-Tr}(\mathcal{C}))$.

**Definition 2.2.2.** For distinguished triangles in $\text{Tr}(\mathcal{C})$ we take the triangles isomorphic to those that come from (2) for any $P, P' \in \text{Pre-Tr}(\mathcal{C})$, $f$ being twisted.

We summarize the properties of Pre-Tr and Tr of [BoK90] that are most relevant for the current paper. We have to replace bounded complexes by complexes bounded from above. Part II4 of the following proposition is new.

**Proposition 2.2.3.** I $\text{Tr}(\mathcal{C})$ is a triangulated category.

II For any additive category $\mathcal{A}$ there are natural isomorphisms

1. $\text{Pre-Tr}(B^- (\mathcal{A})) \cong B^- (\mathcal{A})$.
2. $\text{Tr}(B^- (\mathcal{A})) \cong K^- (\mathcal{A})$.
3. $\text{Pre-Tr}(B(\mathcal{A})) \cong B(\mathcal{A})$.
4. $\text{Tr}(S_N(\mathcal{A})) \cong B^b (\mathcal{A})$

**Proof.** I See Proposition 1 §1 of [BoK90].

II 1,3. See Lemma II.1.2.10 of [Lev98].

2. Immediate from assertion I1.

4. We have natural full embeddings $S_0(\mathcal{A}) \subset S_N(\mathcal{A}) \subset B^b (\mathcal{A})$. Since $\text{Tr}(S_0(\mathcal{A})) \cong \text{Tr}(B^b (\mathcal{A})) \cong B^b (\mathcal{A})$, we obtain the assertion. □
2.3 The categories $\text{Pre-Tr}^+(C)$ and $\text{Tr}^+(C)$

We define certain categories $\text{Pre-Tr}^+(C)$ and $\text{Tr}^+(C)$; our constructions yield categories equivalent to those defined in §4 of [BoK90]. The definitions of $\text{Pre-Tr}^+(C)$ and $\text{Tr}^+(C)$ could also be found in §2.3 of [Dri04]; there these categories were denoted by $C_{\text{pre-tr}}$ and $C_{\text{tr}}$.

**Definition 2.3.1.** $\text{Tr}^+(C)$ is defined as the full (strict) triangulated category of $\text{Tr}(C)$ generated by $[P] : P \in \text{Obj}C$; we denote the corresponding full subcategory of $\text{Pre-Tr}(C)$ by $\text{Pre-Tr}^+(C)$.

The following statement is an easy consequence of the definitions above.

**Proposition 2.3.2.** 1. There are natural embeddings of categories $i : C \to \text{Pre-Tr}^+(C)$ and $H(C) \to \text{Tr}^+(C)$ sending $P$ to $[P]$.

2. $\text{Pre-Tr}(i), \text{Tr}(i), \text{Pre-Tr}^+(i)$, and $\text{Tr}^+(i)$ are equivalences of categories.

**Proof.** 1. By definition of $\text{Pre-Tr}^+(C)$ (resp. of $\text{Tr}^+(C)$) there exists a canonical isomorphism of bifunctors $C(-, -) \cong \text{Pre-Tr}^+(C)([-], [-])$ (resp. $HC(-, -) \cong \text{Tr}^+(C)([-], [-])$). In remains to note that both of these isomorphisms respect addition and composition of morphisms; the first one also respects differentials.

2. The proof was given in §3 and §4 of [BoK90].

**Remark 2.3.3.** 1. Since $\text{Pre-Tr}$, $\text{Pre-Tr}^+$, $\text{Tr}$, and $\text{Tr}^+$ are functors on the category of differential graded categories, any differential category functor $F : C \to C'$ naturally induces functors $\text{Pre-Tr}F$, $\text{Pre-Tr}^+F$, $\text{Tr}F$, and $\text{Tr}^+F$. We will use this fact throughout the paper.

For example, for $X = (P^i, q_{ij}) \in \text{Obj} \text{Pre-Tr}(C)$ we have $\text{Pre-Tr}F(X) = (F(P^i), F(q_{ij}))$; for a morphism $h = (h_{ij})$ of $\text{Pre-Tr}(C)$ we have $\text{Pre-Tr}F(h) = (F(h_{ij}))$. Note that the definition of $\text{Pre-Tr}F$ on morphisms does not involve $q_{ij}$; yet $\text{Pre-Tr}F$ certainly respects differentials for morphisms.

2. Let $F : \text{Pre-Tr}^+(C) \to D$ be a differential graded functor. Then the restriction of $F$ to $C \subset \text{Pre-Tr}^+(C)$ (see Proposition 2.3.2(1)) gives a differential graded functor $FC : C \to D$. Moreover, since $FC = F \circ i$, we have $\text{Pre-Tr}^+(FC) = \text{Pre-Tr}^+(F) \circ \text{Pre-Tr}^+(i)$; therefore $\text{Pre-Tr}^+(FC) \cong \text{Pre-Tr}^+(F)$.

2.4 Definition of $\mathfrak{h}$ and $h$

For $X, Y, Z \in \text{SmPrVar}$, $i, j, l \leq 0$, $f \in C^i(X)(Y)$, $g \in C^j(Y)(Z)$ we have the equality

$$(f^j(g))^l = f^{j+l}(g^l).$$

(3)
Hence we can define a (non-full!) subcategory $J$ of $B^-(Shv(SmCor))$ whose objects are $[P] = C(P)$, $P \in SmPrVar$, the morphisms are defined as

$$J^i(C(P), C(Q)) = \bigl\{ \bigoplus_{l \leq 0} (g) : g \in C^i(Q)(P) \bigr\};$$

the composition of morphisms and the boundary operators are the same as for $B^-(Shv(SmCor))$. There is an obvious addition defined for morphisms; the operation of disjoint union of varieties gives us the addition on objects. It follows immediately from (1) that $J$ is a differential graded subcategory of $B^-(Shv(SmCor))$.

Note that $J^i(-, -) = 0$ for $i > 0$; this is a very important property! In particular, for any $i < 0$, $X, Y, Z \in \text{Obj}J$, it implies that $dJ^i(Y, Z) \circ J^0(X, Y) \subset dJ^i(X, Z)$ and $J^0(Y, Z) \circ dJ^i(X, Y) \subset dJ^i(X, Z)$. This is crucial for the construction of truncation functors $t_N$ (see subsection 6.1 below). We call categories that have no morphisms of positive degree negative differential graded categories; this property will be discussed in subsection 2.7 below.

We define $H$ as $\text{Tr}(J)$. Since $C^l = 0$ for $l > 0$, we have $H = \text{Tr}^+(J)$ (see Remark 6.2.2(2) of [Bon10]). Now Proposition 2.3.2 implies the following statement immediately.

**Proposition 2.4.1.** $H$ is generated by $[P]$, $P \in SmPrVar$, as a triangulated category. Here $[P]$ denotes the object of $H$ that corresponds to $[P] = C(P) \in \text{Obj}J$.

We consider the functor $h: H \to K^-(Shv(SmCor))$ that is induced by the inclusion $J \to B^-(Shv(SmCor))$.

We also note that any differential graded functor $J \to A$ induces a functor $H \to \text{Tr}^+(A)$.

The definition of $H$ implies immediately that $H^i([P], Q[i]) = H^i(C(Q)(P))$ for $P, Q \in SmPrVar$.

### 2.5 An explicit description of $\mathfrak{H}$ and $h$

For the convenience of the reader we describe $\mathfrak{H}$ and $h$ explicitly. Since in this subsection we just describe the category of twisted complexes over $J$ explicitly, we don't need any proofs here.

We define $J' = \text{Pre-Tr}^+(J)$. $J'$ is an enhancement of $H$ (in the sense of [BoK90]). The idea is that taking cones of (twisted) morphisms becomes a well-defined operation in $J'$ (in $H$ it is only defined up to a non-canonical isomorphism).

We describe an auxiliary category $\mathfrak{H}'$. We set $\text{Obj}\mathfrak{H}' = \text{Obj}J' = \text{Obj}\mathfrak{H}$, whereas $\mathfrak{H}'(X, Y) = \text{Ker} \delta^0_{j^!(X, Y)}$ for $X, Y \in \text{Obj}\mathfrak{H}'$. 

Hence the objects of $\mathcal{H}'$ are $(P^i, i \in \mathbb{Z}, f_{ij}, i < j)$, where $(P^i)$ is a finite sequence of (not necessarily connected) smooth projective varieties (we assume that almost all $P^i$ are 0), $f_{ij} \in C^{i-j+1}(P^j)(P^i)$ for all $m, n \in \mathbb{Z}$ satisfy the condition
\[
\delta^{m-n+1}(P^n)(f_{mn}) + \sum_{m<l<n} f_{ln}^{m-l+1}(f_{ml}) = 0.
\]

Morphisms $g : A = (P^i, f_{ij}) \rightarrow B = (P'^{i}, f'_{ij})$ can be described as sets $(g_{ij}) \in C^{i-j}(P^j)(P'^i), i \leq j$, where the $g_{ij}$ satisfy
\[
\delta_{P'^i}^{i-j}(g_{ij}) + \sum_{j \geq l \geq i} f'_{lj}^{i-l}(g_{il}) = \sum_{j \geq l \geq i} g_{lj}^{i-l+1}(f_{il}) \forall i, j \in \mathbb{Z}.
\]
We will assume that $g_{ij} = 0$ for $i > j$.

Note that $g_{ij} = 0$ if $P^i = 0$ or $P'^i = 0$. Hence the morphisms for any pair of objects in $\mathcal{H}'$ are defined by means of a finite set of equalities.

The composition of $g = (g_{ij}) : A \rightarrow B$ with $h = (h_{ij}) : B \rightarrow C = (P'^i, f'_{ij})$ is defined as
\[
l_{ij} = \sum_{i \leq r \leq j} h_{ir}^{r-i}(g_{ir}).
\]

$\mathcal{H}'$ has a natural structure of an additive category. The direct sum of objects is defined by means of a disjoint union of varieties.

The morphisms $g, h : A = (P^i, f_{ij}) \rightarrow B = (P'^i, f'_{ij})$ are called homotopic ($g \sim h$) if there exist $l_{ij} \in C^{i-j-1}(P^j)(P'^i), i - 1 \leq j$, such that
\[
g_{ij} - h_{ij} = \delta_{P'^i}^{i-j-1}l_{ij} + \sum_{i-1 \leq r \leq j} f'_{rj}^{i-r-1}(l_{ir}) + \sum_{i \leq r \leq j+1} l_{rj}^{i-r+1}(f_{ir}).
\]

Now $\mathcal{H}$ can be described as a category whose objects are the same as for $\mathcal{H}'$, whereas $\mathcal{H}(A, B) = \mathcal{H}'(A, B)/ \sim$. The translation on $\mathcal{H}$ is defined by shifts of indices (for $P^i, f_{ij}$). For $g = (g_{ij}) \in \mathcal{H}'(A, B)$ its cone is defined as $C = Cone(g) \in Obj\mathcal{H}'$, the $i$-th term of $C$ is equal to $P^{ni} = P^{i+1} \oplus P^n$, whereas
\[
h_{ij} \in C^{i-j+1}(P^{i+1} \oplus P'^i)(P^{i+1} \oplus P^n) = \begin{pmatrix}
                     f_{i+1,j+1} & 0 \\
g_{i+1,j} & f'_{ij}
                   \end{pmatrix}, i < j;
\]
we have obvious natural maps $B \rightarrow C \rightarrow A[1]$.

It is easily seen that $\mathcal{H}$ coincides with the category defined in 2.4. We denote the projection $\mathcal{H}' \rightarrow \mathcal{H}$ by $j$.

Moreover, as in Theorem 4.6 of [Han04], one can check (without using the formalism described above) that $\mathcal{H}$ with the structures defined is a triangulated category. One can also check directly that $P[0]$ for $P \in SmPrVar$ generate $\mathcal{H}$ as a triangulated category.
For \( A = (P^i, f_{ij}) \in \text{Obj}(\mathcal{H}') \) we define \( h'(A) \in C^-(\text{Shv} \, \text{SmCor}) \) as \((C_A^j, \delta_A^j : C_A^j \to C_A^{j+1}) \in C^-(\text{Shv} \, \text{SmCor})\). Here \( C^j_A = \sum_{i \leq j} C^{i-j}(P^i) \), the component of \( \delta_A^j \) that corresponds to the morphism of \( C^{i-j}(P^i) \) into \( C^{i-j+1}(P^{j'}) \) equals \( \delta_{P^j}^{j'} \) for \( j = j' \) and equals \( f_{ij}^{j-j'} \) for \( j' \neq j \).

Note that the condition (1) implies \( d^2_{h(A)} = 0 \).

Now we define \( h' \) on morphisms. For \((l_{ij}) : A \to B, s \in \mathbb{Z}, \) we set \( h'(l)^s = \oplus_{i,j} l_{ij}^{s-i} \).

One can check explicitly that \( h' \) induces an exact functor \( h : \mathcal{H} \to K^-(\text{Shv} \, \text{SmCor}) \).

By abuse of notation we denote by \( h' \) also the functor \( J' \to B^-(\text{Shv} \, \text{SmCor}) \).

Remark 2.5.1. \( P^i \) should be thought about as being 'stratification pieces' of the motif \( A = (P, f) \). In particular, let \( Z \) be closed in \( X, Z, X \in \text{SmPrVar}, Y = X - Z; \) suppose that \( Z \) is everywhere of codimension \( c \) in \( X \). If we adjoin \( Z(c)[2c] \) to \( \text{Obj} J \) (see subsection 8.5) then \( M_{gm}(Y) \) can be presented in \( \mathcal{H} \) as \(((X, Z(c)[2c]), g_Z)\), where \( g_Z \) is the Gysin morphism (see Proposition 3.5.4 of [Voe00a]). See also Proposition 6.5.1 for a nice explicit description of the motif with compact support of any smooth quasi-projective \( X \).

The main distinction of \( \mathcal{H} \) from the motivic category \( D \) defined by Hanamura (see [Han95], [Han04], and [11]) is that the Bloch cycle complexes (used in the definition of \( D \)) are replaced by the Suslin complexes; we never have to choose distinguished subcomplexes for our constructions (in contrast with [Han95]). Note also that our definition works on the integral level in contrast with those of [Han95].

2.6 'Stupid filtration' for motives

As we will see several times below, the category \( \mathcal{H} \) (hence also \( DM^* \), cf. Theorem 3.1.1) is very close to \( K^b(\text{Corr}_{rat}) \). In a certain sense, \( \mathcal{H} \) has 'stupid filtration' related to those of \( K^b(\text{Corr}_{rat}) \). Certainly, this filtration is only defined on the level of \( \mathcal{H}' \) (note that the stupid truncation of an object of \( K^b(\text{Corr}_{rat}) \) depends on its lift to \( C^b(\text{Corr}_{rat}) \)).

Proposition 2.6.1. Let \( X = (P^i, f_{ij}) \) (as in subsection 2.5).

1. For any \( a \leq b \in \mathbb{Z} \) the set \((P^i, f_{ij} : a \leq i, j \leq b)\) gives an object \( X_{[a,b]} \) of \( \mathcal{H}' \) (and so also of \( \mathcal{H} \)).

2. If \( P^i = 0 \) for \( i < a \) then \( id_{P^i} : i \leq b \) gives a morphism \( X \to X_{[a,b]} \) (in \( \mathcal{H}' \) and \( \mathcal{H} \)).

3. If \( P^i = 0 \) for \( i > b \) then \( id_{P^i} : i \leq b \) gives a morphism \( X_{[a,b]} \to X \).

4. If \( P^i = 0 \) for \( i < a \) and for \( i > c, a < b < c \), then we have a distinguished triangle \( X_{[a,b]} \to X \to X_{[b,c]} \).
Proof. 1. We have to check that the equality (4) is valid for $X_{[a,b]}$. Yet all terms of (4) are zero unless $a \leq i \leq j \leq b$. Moreover, in the case $a \leq i \leq j \leq b$ the terms of (4) are the same as for $X$. Both of these facts follow immediately from the negativity of $J$.

2,3: we have to check the condition (5) for these cases; again this is obvious by the negativity of $J$.

4. We should check that $X \rightarrow X_{[b,c]}$ is homotopy equivalent to the second morphism of the triangle corresponding to $X_{[a,b]} \rightarrow X$; this easily follows from (2) (see also the corresponding part of subsection 2.5).

The definition of the stupid filtration and its properties are quite similar to those described in §1 of [Han99] (see property (6) in the end of that section). Note that we only used the fact that there are no morphisms of positive degree between objects of $J$. See [Bon10] for a vast generalization of this observation.

2.7 Other generalities on differential graded categories

We describe some new differential graded categories and differential graded functors. We will need them in section 7 below.

2.7.1 Differential graded categories of morphisms

For an additive category $A$ we denote by $MS(A)$ the category of morphisms of $S(A)$. Its objects are \{$(X, Y, f) : X, Y \in \text{Obj}A, f \in A(X,Y)$\};

$$MS_0((X, Y, f), (X', Y', f')) = \{(g, h) : g \in A(X,X'), h \in A(Y,Y'), f' \circ g = h \circ g\}.$$  

As for $S(A)$, there are no morphisms of non-zero degree in $MS(A)$; hence the differential for morphisms is zero.

We denote Pre-Tr($MS(A)$) by $MB^b(A)$. We recall that a twisted morphism is a closed morphism of degree 0, i.e., an element of the kernel of $\delta^0$.

**Proposition 2.7.1.** 1. $MB^b(A)$ is the category of closed morphisms of $B^b(A)$ (cf. §2.10 of [Dri04]). That means that its objects are \{$(X, Y, f) : X, Y \in \text{Obj}B(A), f \in \text{Ker}\delta^0(B(A)(X,Y))$\},

$$MB^b((X, Y, f), (X', Y', f')) = \{(g, h) : g \in B(A)^i(X, X'), h \in B(A)^i(Y, Y'), f' \circ g = h \circ f\}.$$  

2. Let $MB(A)$ denote the unbounded analogue of $MB^b(A)$. Then Pre-Tr($MB(A)$) $\cong$ $MB(A)$.  

20
3. Let \( \text{Cone} : MB(A) \to B^b(A) \) denote the natural cone functor. Then the functor \( \text{Pre-Tr}(\text{Cone}) \) is naturally isomorphic to \( \text{Cone} \).

Proof. 1. Easy direct verification.

2. The proof is very similar to those of part II1 of Proposition 2.2.3. First we note that \( \text{Pre-Tr}(MB^bB(A)) \cong MB^b(A) \), then extend this to the unbounded analogue.

3. Obviously, \( \text{Cone} \) is a differential graded functor. Hence it remains to apply part 2 of Remark 2.3.3.

We have obvious differential graded functors \( p_1, p_2 : MB(A) \to B(A) \):
\[
p_1(X, Y, f) = X, \quad p_2(X, Y, f) = Y.
\]

**Corollary 2.7.2.** Let \( F : J \to MB(A) \) be a differential graded functor.

1. \( \text{Pre-Tr}(F) \) gives a functorial system of closed morphisms \( \text{Pre-Tr}(p_1 \circ F)(X) \to \text{Pre-Tr}(p_2 \circ F)(X) \) in \( B(A) \) for \( X \in \text{Obj} J' = \text{Obj} \mathcal{H} \).

2. Let \( A \) be an abelian category. Suppose that for any \( P \in \text{SmPrVar} \) the complex \( F([P]) \) is exact. Then there exists a natural quasi-isomorphism \( \text{Tr}^+(p_1 \circ F)(X) \sim \text{Tr}^+(p_2 \circ F)(X) \) for \( X \in \text{Obj} \mathcal{H} \).

Proof. 1. Obvious.

2. We have to show that \( \text{Pre-Tr}^+(\text{Cone}(F))(X) \) is quasi-isomorphic to 0 for any \( X \in \text{Obj} J' \). We consider the exact functor \( G = \text{Tr}^+(\text{Cone}(F))(X) \); it suffices to show that \( G = 0 \). Recall that \([P], P \in \text{SmPrVar}, \) generate \( \mathcal{H} \) as a triangulated category. Hence \( G([P]) = 0 \) for any \( P \in \text{SmPrVar} \) implies that \( G = 0 \).

2.7.2 Negative differential graded categories; truncation functors

We recall that a differential graded category \( C \) is called negative if \( C^i(X, Y) = 0 \) for any \( i > 0, X, Y \in \text{Obj} C \).

Certainly in this case all morphisms of degree zero are closed (i.e., satisfy \( \delta f = 0 \)). This notion is very important for us since \( J \) is negative.

For any differential graded \( C \) there exist a unique 'maximal' negative subcategory \( C_- \) (it is not full unless \( C \) is negative itself!). The objects of \( C_- \) are the same as for \( C \), whereas \( C_{-, i}(X, Y) = 0 \) for \( i > 0 \), \( = C^i(X, Y) \) for \( i < 0 \), \( = \text{Ker} \delta^0(C(X, Y)) \) for \( i = 0 \).

Obviously, if \( F : D \to C \) is a differential graded functor, \( D \) is negative, then \( F \) factors through the faithful embedding \( C_- \to C \).

Suppose that \( A \) is an abelian category.

Then zeroth (or any other) cohomology defines a functor \( B_-(A) \to S(A) \).

More generally, we define two versions of the canonical truncation functor for \( B_-(A) \). We will need these functors in subsection 7.3 below.
Let $X$ be a complex over $A$, $a, b \in \mathbb{Z}$, $a \leq b$. We define $\tau_{\leq b}$ as the complex

$$\cdots \rightarrow X^{b-2} \rightarrow X^{b-1} \rightarrow \text{Ker}(X^b \rightarrow X^{b+1}),$$

here $\text{Ker}(X^b \rightarrow X^{b+1})$ is put in degree $b$. $\tau_{[a, b]}(X)$ is defined as $\tau_{\leq b}(X)/\tau_{\leq a-1}(X)$ i.e., it is the complex

$$X^{a-1}/\text{Ker}(X^{a-1} \rightarrow X^a) \rightarrow X^a \rightarrow X^{a+1} \rightarrow \cdots \rightarrow X^{b-1} \rightarrow \text{Ker}(X^b \rightarrow X^{b+1}).$$

The canonical $[a, b]$-truncation of $X$ for $a < b$ is defined as

$$X^{[a, b]} = X^a/dX^{a-1} \rightarrow X^{a+1} \rightarrow \cdots \rightarrow X^{b-1} \rightarrow \text{Ker}(X^b \rightarrow X^{b+1}),$$

again $\text{Ker}(X^b \rightarrow X^{b+1})$ is put in degree $b$; for $a = b$ we take $H^a(X)$. Recall that truncations preserve homotopy equivalence of complexes.

**Proposition 2.7.3.** 1. $\tau_{\leq b}$, $\tau_{[a, b]}$, and the canonical $[a, b]$-truncation define differential graded functors $B_-(A) \rightarrow B_-(A)$.

2. Let $F : J \rightarrow B(A)$ be a differential graded functor; we can assume that its target is $B_-(A)$. We consider the functors $\tau_{[a, b]}F$ and $F_{[a, b]}$ that are obtained from $F$ by composing it with the corresponding truncations. Then there exists a functorial family of quasi-isomorphisms $Tr^+(\tau_{[a, b]}F)(X) \rightarrow Tr^+(F_{[a, b]})(X)$ for $X \in \text{Obj} \mathcal{J}$.

**Proof.** 1. Note that all truncations give idempotent endofunctors on $C(A)$.

Hence it suffices extend truncations to all morphisms of $B_-(A)$ and prove that truncations respect $\delta$.

The definition of truncations on morphisms of negative degree is very easy. The only morphisms in $B_-(A)$ of degree zero are twisted ones, i.e., morphisms coming from $C(A)$.

It remains to verify that if a given truncation $\tau$ of a morphism $f = (f_i) : (X^i) \rightarrow (Y^i)$ in $B_-(A)$ is zero then $\tau(\delta f) = 0$.

First we check this for $\tau = \tau_{\leq b}$. $\tau_{\leq b}f = 0$ means that $f(\tau_{\leq b}X) = 0$ (i.e., the corresponding restrictions of $f_i$ are zero). Since the boundary maps $\tau_{\leq b}X$ into itself, the definition of $\delta$ for $B(A)$ gives the result.

Now we consider the case $\tau = \tau_{[a, b]}$. $\tau_{[a, b]}(f) = 0$ means that $f(\tau_{\leq b}X) \subset \tau_{\leq a}Y$. Again it suffices to note that the boundary maps $\tau_{\leq b}X$ and $\tau_{\leq a}Y$ into themselves.

The case of canonical truncation can be treated similarly.

2. The natural morphism $m([P]) : \tau_{[a, b]}F([P]) \rightarrow F_{[a, b]}([P])$ gives a functor $H : J \rightarrow MB(A)$ such that $p_1(H) = \tau_{[a, b]}F$ and $p_1(H) = F_{[a, b]}$. It remains to note that $m([P])$ is a quasi-isomorphism for any $P \in \text{SmPrVar}$ and apply part 2 of Corollary 2.7.2.

\[\square\]
Remark 2.7.4. 1. Another way to obtain new differential graded categories is to take 'tensor products' of differential graded categories. In particular, one can consider the categories \( J \otimes J \) and \( Tr(J \otimes J) \) (which could be denoted by \( J \otimes J \)).

2. If \( H^i(C(X,Y)) = 0 \) for some differential graded category \( C \), any \( X,Y \in ObjC \), \( i > 0 \), then \( Tr^+(C_-) \sim Tr^+(C) \). Indeed, the embedding \( C_- \to C \) gives a functor \( F : Tr^+(C_-) \to Tr^+(C) \). Then an easy argument shows that \( F \) is a full embedding; see part 3 of Remark 3.1.2 below. Lastly, since \( ObjC \) generates \( Tr^+(C) \) is a triangulated category, one can easily prove (by induction) that \( F \) gives an equivalence, i.e., that any \( X \in ObjTr^+(C) \) is isomorphic to some \( Y \in F_*(ObjTr^+(C_-)) \).

3. One can also define positive differential graded categories in a natural way. Positive differential graded categories seem to be related with \( t \)-structures. Yet we will not study this issue in the current paper.

3  The main classification result

In this section we prove the equivalence of \( \mathcal{S} \) and \( DM^s \). It follows that the presentation of a motif as \( m(X) \) for \( X \in \mathcal{S} \) could be thought about as being a 'motivic injective resolution'.

Unfortunately, we don’t know how to compare Voevodsky’s \( DM^eff_{gm} \) (or just \( SmVar \)) with \( \mathcal{S} \) 'directly'.

In \( \S 3.3 \) we define the Tate twist \( \otimes \mathbb{Z}(1) \) on \( \mathcal{S} \). We formally invert it; this provides us with a certain differential graded description of Voevodsky’s \( DM^s_{gm} \).

3.1  The equivalence of categories \( m : \mathcal{S} \to DM^s \)

We denote the natural functor \( K^-(Shv(SmCor)) \to D^-(Shv(SmCor)) \) by \( p \), denote \( p \circ h \) by \( m \).

Theorem 3.1.1. \( m \) is a full exact embedding of triangulated categories; its essential image is \( DM^s \).

Proof. Since \( h \) is an exact functor, so is \( m \). Now we check that \( m \) is a full embedding. By part 2 of Proposition 1.3.1, \( m \) induces an isomorphism \( DM^{eff\Sigma}(\mathcal{S}) \cong \mathcal{S} \) for \( P,Q \in SmPrVar \), \( i \in \mathbb{Z} \). Since \( [R], R \in SmPrVar \), generate \( \mathcal{S} \) as a triangulated category (see Proposition 2.4.1), the same is true for any pair of objects of \( \mathcal{S} \) (cf. part 3 of Remark 3.1.2 below).

We explain this argument in more detail.

23
First we verify that for any smooth projective $P/k$ and arbitrary $B \in \mathcal{H}$ the functor $m$ gives an isomorphism

\[ DM^eff([P]), m(B)) \cong \mathcal{H}([P]), B). \tag{7} \]

By Proposition 1.3.1 (7) is fulfilled for $B = P'[j]$, $j \in \mathbb{Z}$, $P' \in SmPrVar$. For any distinguished triangle $X \to Y \to Z \to X[1]$ in $\mathcal{H}$ the functor $m$ defines a morphism of long exact sequences

\[ \to \mathcal{H}([P], Y) \longrightarrow \mathcal{H}([P], Z) \longrightarrow \mathcal{H}([P], X[1]) \to \]

\[ \to DM^eff([P]), m(Y)) \longrightarrow DM^eff([P]), m(Z)) \longrightarrow DM^eff([P], m(X)[1]) \to \]

Thus if $m$ gives an isomorphism in (7) for $B = X[i]$ and $B = Y[i]$ for $i = 0, 1$, then $m$ gives an isomorphism for $B = Z$. Since objects of the form $B = [P]$ generate $\mathcal{H}$ as a triangulated category, (7) is fulfilled for any $B \in \mathcal{H}$. Hence for all $i \in \mathbb{Z}$, $B \in \mathcal{H}$, we have $DM^eff([P[i]), m(B)) \cong \mathcal{H}(P[i], B)$. For any distinguished triangle $X \to Y \to Z \to X[1]$ in $\mathcal{H}$ the functor $m$ defines a morphism of long exact sequences $(\cdots \to \mathcal{H}(Z, B) \to \cdots) \to (\cdots \to DM^eff([P], m(B)) \to \cdots)$ similar to (8). Now the same argument as above proves that $m$ is a full embedding.

It remains to calculate the ‘essential image’ $M$ of the map that is induced by $m$ on $Obj(\mathcal{H})$ (we adjoin to $M$ all objects that are isomorphic to those coming from $\mathcal{H}$). According to Proposition 5.2.2 below we have $m([P]) = C(P) \cong M_{gm}(P)$.

Since $\mathcal{H}$ is generated by $[P]$ for $P \in SmPrVar$ as a triangulated category, $M$ is the strict triangulated subcategory of $DM^eff$ that is generated by all $M_{gm}(P)$. Since the tensor structure on $DM^eff$ is defined by means of the relation $M_{gm}(X) \otimes M_{gm}(Y) = M_{gm}(X \times Y)$ for $X, Y \in SmVar$, $M$ is a tensor subcategory of $DM^eff$. Since $M_{gm}(P) \in ObjDM^s$ for any $P \in SmPrVar$, we have $M \subseteq DM^s$. It remains to prove that $M$ contains $DM^s$. Now, $\mathbb{Z}(1)[2] \in DM^eff$ can be represented as a cone of $M_{gm}(pt) \to M_{gm}(\mathbb{P}^1)$ (we will identify $\mathbb{Z}(1)$ with $M_{gm}(\mathbb{Z}(1))$). Hence $\mathbb{Z}(n) \in ObjM$ for any $n > 0$. Since $M_{gm}$ is a tensor functor, if $M_{gm}(Z) \in ObjM$ for $Z \in SmVar$, then $\mathbb{Z}(c)[2c] \in ObjM$ for all $c > 0$. Now we apply Proposition 3.5.4 of [Voe00a] as well as the Mayer-Vietoris triangle for motives (§2 of [Voe00a]); similarly to Corollary 3.5.5 of [Voe00a] we conclude that $ObjM$ contains all $M_{gm}(X)$ for $X \in SmVar$ (cf. the remark in [Voe00a] that precedes Definition 2.1.1). A more detailed version of this argument will be used in the proof of Theorem 6.2.1 below.

24
Since $DM^s$ is the smallest triangulated subcategory of $DM^{eff}$ containing motives of all smooth varieties, we prove the claim.

**Remark 3.1.2.** 1. In order to calculate $DM^{eff}(M, M')$ for $M, M' \in DM^s$ (using the explicit description of $\mathcal{S}$ given in subsection 2.5) in terms of cycles one needs to know $m^{-1}(M)$ and $m^{-1}(M')$ (or the preimages of their duals). See subsection 5.5 for a nice result in this direction.

2. Note that we do not construct any comparison functor $DM^s \to H$ (or $SmVar \to H$) explicitly. Yet if we denote by $SmCor_{pr}$ the full subcategory of $SmCor$ whose objects are smooth projective varieties, then we have obvious functors $SmCor_{pr} \to K_b(SmCor_{pr}) \to H$. Note that the Voevodsky’s description of $DM^{eff}_{gm}$ also gives a canonical functor $K_b(SmCor_{pr}) \to DM^s \subset DM^{eff}_{gm}$.

3. Exactly the same argument as used in the (first part of the) proof in fact immediately proves the following (general and well-known) statement. Let $r : C \to D$ be an exact functor (i.e., $C, D$ are triangulated categories); let $S$ be a class of objects of $C$ that generate it as a triangulated category. Then $r$ is a full embedding if and only if it induces isomorphism $C(X, Y[i]) \to D(r(X), r(Y[i]))$ for all $i \in \mathbb{Z}, X, Y \in S$.

We will use this statement for $S = \{[P], P \in SmPrVar\}$, $C = \mathcal{S}$ or $\mathcal{S} \otimes \mathbb{Q}$, below.

### 3.2 On motives of (possibly) singular varieties

Recall (see §4.1 of [Voe00a]) that for any $X \in Var$ (not necessarily smooth!) there were certain objects $M_{gm}(X)$ and $M^{c}_{gm}(X)$ of $DM^{eff}$ defined. $M_{gm}(X)$ was called the motif of $X$; $M^{c}_{gm}(X)$ was called the motif of $X$ with compact support.

The following statement follows easily.

**Corollary 3.2.1.** For any (not necessarily smooth) variety $X/k$ there exist $Z, Z' \in \mathcal{S}$ such that $m(Z) \cong M_{gm}(X)$, $m(Z') \cong M^{c}_{gm}(X)$.

**Proof.** It is sufficient to verify that $M_{gm}(X), M^{c}_{gm}(X) \in DM^s$. The proof of this fact is the same as for Corollaries 4.1.4 and 4.1.6 in [Voe00a]. Indeed, for the proofs in [Voe00a] one doesn’t need to add the kernels of projectors.

**Remark 3.2.2.** We obtain that for the Suslin complex of an arbitrary variety $X$ there exists a quasi-isomorphic complex $M$ ‘constructed from’ the Suslin complexes of smooth projective varieties; $M \in h_*(Obj\mathcal{S}) \subset ObjK^-(Shv(SmCor))$ is unique up to a homotopy.
Moreover, as we have noted in the proof of Lemma 5.2.1, the cohomology of $C(P)$ as a complex of presheaves for any $P \in SmPrVar$ coincides with its hypercohomology (the corresponding fact for $C(P)$ was proved in [Voe00a]). Hence the same is true for any $M \in h_\ast(Obj\mathcal{F})$. Hence for $X \in SmVar$ the quasi-isomorphism $C(X) \to M$ is given by an element of $H^0(M)(X)$.

This result shows that the presentation of a motif as $m(X)$ for $X \in H$ could be thought about as being a ‘motivic’ analogue of taking an injective resolution; here the Suslin complexes of smooth projective varieties play the role of injective objects.

3.3 Tensor products, direct summands and non-effective motives ($DM_{gm}$)

For any $P \in SmPrVar$ one can in the obvious way define a differential graded functor $- \otimes [P]$ that maps $[Q] \in Obj\mathcal{J}$ to $[Q \times P]$. Applying $Tr$ to it, one gets an exact functor $- \otimes [P] : H \to H$. More generally, for any $C \in C^b(J^0)$ one can easily define an exact functor $- \otimes [C] : \mathcal{H} \to \mathcal{H}$; the construction is very similar to the construction of a tensor product on $K^B(A)$ for a tensor additive category $A$). This tensor product will also map $[Q], Q \in SmPrVar$, to the naturally defined complex $[Q \times C]$. We will present the motif $Z(1)$ as $([pt] \to [\mathbb{P}^1])[-2]$ and define a functor $\otimes \mathbb{Z}(1)$ using this construction; we will denote this functor by $-(1)$. For $n \geq 0$ we will denote by $X(n)$ the $n$-th iteration of $-(1)$ applied to $X \in Obj\mathcal{H}$. Note that there exists a functorial isomorphism $X(1)[2] \oplus X \cong X \otimes \mathbb{P}^1$.

Now we define $\mathcal{H}_{gm}$ as $\lim_{\rightarrow} -(1)$, i.e., it is the category whose objects are $(X, m) : X \in Obj\mathcal{H}, m \in \mathbb{Z}$;

$\mathcal{H}_{gm}((X, m), (X', m')) = \lim_{\rightarrow} \mathcal{H}(X(n + i), X'(n' + i))$

(note that these groups are only defined in the case $n + i, n' + i \geq 0$). Note that $-(1)$ can be extended to $\mathcal{H}_{gm}$; $\mathcal{H}_{gm}$ is a triangulated category.

Next, we recall that $DM_{gm}$ is a tensor triangulated category, and the corresponding functor $\otimes \mathbb{Z}(1) : DM_{gm} \to DM_{gm}$ is fully faithful. Following Voevodsky we define $DM_{gm}$ in a similar way as $\lim_{\rightarrow} -(1) \ DM_{gm}$. Besides, recall that $-(1)$ is a full embedding of $DM_{gm}$ (and hence also of $DM_{gm}$) into itself; this is the Cancellation Theorem (see Theorem 4.3.1 of [Voe00a] or [Voe10] for the characteristic $p$ case).

Unfortunately, the author does not know how to compare the twist functors (i.e., $-(1)$) on $\mathcal{H}$ and $DM_{gm}$ in the general case. Still, they take on
the same values’ on $P[i]$, $P \in \text{SmPrVar}, i \in \mathbb{Z}$; this turns to suffice for comparison of $\mathcal{H}_{gm}$ with $DM_{gm}$.

**Proposition 3.3.1.** 1. The idempotent completion of $\mathcal{H}_{gm}$ is equivalent to $DM_{gm}$.

2. The functor $- \otimes \mathbb{Z}(1)$ is an autoequivalence of $\mathcal{H}_{gm}$.

**Proof.** 1. First we verify that $-(1)$ is a full embedding of $\mathcal{H}$ into itself.

By part 3 of Remark 3.1.2 to this end it suffices to prove that for any $P, Q \in \text{SmPrVar}, i \in \mathbb{Z}$ the map $\mathcal{H}([P], Q[i]) \to \mathcal{H}(P(1), Q[i](1))$ induced by $-(1)$ is an isomorphism. The latter fact easily follows from the results of §8 of [FrV00] (that the suspension map is an isomorphism).

Now we recall that by the definition of the tensor product on $DM_{gm}^{eff}$ (see §3 of [Voe00a]; note that the product can be extended to $DM_{gm}^{eff}$ for any $P \in \text{SmPrVar}$ we have $m([P](1)) \cong M_{gm}(P) \otimes \mathbb{Z}(1)$. This fact along with the Cancellation Theorem (see above) easily implies that $\text{Obj} \mathcal{H}(i) \cong \text{Obj} DM_{gm}^{eff}(i)$ for any $i \geq 0$. Here by $\approx$ we means that (via the isomorphism $m$ of Theorem 3.1.1) any object of $\mathcal{H}(i)$ is isomorphic to an object of $DM_{gm}^{eff}(i)$ (here the twist is defined as in $DM_{gm}^{eff}$) and vice versa. Indeed, both categorical images in question are generated (as triangulated categories) by $[P](i), P \in \text{SmPrVar}$.

Now, by Lemma 3.3.3 below we have $\lim_{(1)} DM_{gm}^{eff} \cong \mathcal{H}_{gm}$. Since idempotent completions commute with the operation $C \to \lim_{(1)} C$ in the case when $-(1)$ is a full embedding, we obtain the claim.

2. Since $-(1)$ is a full embedding of $\mathcal{H}$ into itself, the same is true on $\mathcal{H}_{gm}$.

Now, we consider a full (triangulated) subcategory $H$ of $\mathcal{H}$ that is obtained by leaving exactly one element in each class of isomorphic objects in $\mathcal{H}$ and define $H_{gm} = \lim_{(1)} H$. Clearly, $H_{gm}$ is isomorphic to $\mathcal{H}_{gm}$, whereas $-(1)$ is invertible on $H_{gm}$.

\[\]
Lemma 3.3.3. Let $C$ be a category, let $F, F'$ be full embeddings of $C$ into itself. Suppose that for any $i \geq 0$ each object of $F^i(C)$ is isomorphic to some object of $F'^i(C)$ and vice versa; here $F^i, F'^i$ denote the corresponding $i$-th iteration functors. Then $\lim_{\rightarrow F} C \cong \lim_{\rightarrow F'} C$.

Proof. We can assume that each isomorphism class of objects in $C$ consists of a single object. Then $\text{Obj} F^i(C) = \text{Obj} F'^i(C)$.

It follows that the following functors are well-defined (invertible) auto-equivalences of $C$: for $i > 0$ we consider $G_i = F'^{-i} \circ F^i$, for $i \leq 0$ we define $G_i = F^i \circ F'^{-i}$. Here $F^l, F'^l$ for $l \leq 0$ denote the composition inverses of $F^{-l}, F'^{-l}$.

Now, it remains to note that sending $(X, m) \in \lim_{\rightarrow F} C$ to $(G_m(X), m) \in \lim_{\rightarrow F'} C$ for all $m \in \mathbb{Z}$ defines an equivalence of the categories in question (one can easily construct the inverse functor).

\[ \Box \]

4 Comparison of $DM_{gm} \mathbb{Q}$ with Hanamura’s category of motives

We prove that $DM_{gm} \mathbb{Q}$ is anti-isomorphic to the Hanamura’s triangulated category of motives.

Prof. Hanamura has kindly informed the author that he has (independently) obtained an alternative proof of the anti-equivalence of motivic categories; his proof uses the extension of the functor constructed in [Han00]. Unfortunately, Hanamura’s proof is not available for the public (in any form).

4.1 The plan

We will not recall Hanamura’s definitions in detail here (they are rather long) so the reader should consult §2 of [Han95] for the definition of $\mathcal{D}_{fin(k)}$ and $\mathcal{D}(k)$ (see also §4 of [Han04] and §4.5 [Lev05]). One of unpleasant properties of Hanamura’s construction is that it uses a certain composition operation for Bloch’s complexes (see below) which is only partially defined. Yet on the target of our comparison functor the composition is always defined.

Note that Hanamura’s category is cohomological (i.e., the functor $SmPrVar \to \mathcal{D}_{fin(k)}$ is contravariant); so it’s natural to consider contravariant functors $\mathcal{D} \to \mathcal{D}_{fin(k)}$. For that reason we will consider the categories $\mathcal{D}^{op}_{fin} \subset \mathcal{D}^{op}$ that equal $\mathcal{D}_{fin}(k)^{op} \subset \mathcal{D}(k)^{op}$.

$\mathcal{D}^{op}_{fin}$ could ‘almost’ be described as $Tr(I)$ for a certain differential graded $I$. The problem is that composition of morphisms in $I$ is only partially
defined; overcoming this difficulty makes the construction rather complicated. Moreover, in our definition of $H$ we use not necessarily connected $P \in \text{SmPrVar}$. In Hanamura’s notation $P$ should be replaced by $\oplus P^i$, where $P^i$ are connected components of $P$; yet we will ignore this distinction below.

The proof consists of three parts.

I Construction of a functor $F : H \otimes Q \to D_{\text{fin}}^{\text{op}}$.
II Proof that $F$ is a full embedding.
III Proof that $F$ extends to an equivalence $\text{DM}_{\text{gm}} Q \to D^{\text{op}}$.

4.2 Construction of a comparison functor $F$

First we modify $H \otimes Q$ slightly. We define $JQ$ as the category whose objects are the same as for $J$ while the morphisms are given by rational alternated cubical Suslin complexes. These are defined similarly to the alternated cubical Bloch complexes. Let $\Sigma_n$ for $n \geq 0$ denote the group of permutations of $n$ elements; it acts on $A_n$ by permuting coordinates.

We define

$$JQ^i([P], [Q]) = Q \otimes \{a_i(f) : f \in J^i([P], [Q])\} \subset Q \otimes J^i([P], [Q])$$

for all $i \in \mathbb{Z}$, $P, Q \in \text{SmPrVar}$. Here $a_i$ is the idempotent $(\sum_{\sigma \in \Sigma_{-i}} \text{sgn}(\sigma) \sigma)/(-i)!$, $\text{sgn}(\sigma)$ is the sign of a permutation. One can easily see that $(a_i)$ is an endomorphism of the complex of $Q \otimes J([P], [Q])$, i.e., we can consider the boundaries of $JQ$ induced by those of $J$ (note that $JQ$ is a direct summand of $J \otimes Q$).

We define the composition of morphisms in $JQ$ as in a factor-category of $J \otimes Q$. It is possible since for any $i, j \in \mathbb{Z}$, $P, Q, R \in \text{SmPrVar}$, $f \in J^i(P, Q)$, $g \in J^j(Q, R)$ we have $a_{i+j}(g \circ f) = a_{i+j}(a_j(g) \circ a_i(f))$ (an easy direct verification).

An easy standard argument (see Lemma 2.28 of [Lev05]) shows immediately that the alteration procedure gives a quasi-isomorphism $J([P], [Q]) \otimes Q \to JQ([P], [Q])$ for any $P, Q \in \text{SmPrVar}$. Hence (by part 3 of Remark 3.1.2) there exists an equivalence of categories $G : \mathcal{H} \otimes Q \to \mathcal{H}Q$, where $\mathcal{H}Q = Tr(JQ)$.

Hence for our purposes it suffices to construct a natural embedding $H : \mathcal{H}Q \to D_{\text{fin}}^{\text{op}}$. As we have said above, $D_{\text{fin}}^{\text{op}}$ is ‘almost equal’ to $\text{Tr}(I)$ for a certain differential graded ‘almost category’ $I$. Hence it suffices to define a certain differential graded functor $G : JQ \to I$ and define $H = \text{Tr}G$. Indeed, the ‘image’ of $H$ will be a subcategory of $D_{\text{fin}}^{\text{op}}$ (not necessarily full) which composition of morphisms is compatible with those of $\mathcal{H}Q$; we don’t have to care of morphisms and object of $D_{\text{fin}}^{\text{op}}$ that do not come from $\mathcal{H}Q$. 

29
We describe $I$. Let $Z_r(X)$ for $X \in SmVar$, $r \geq 0$, denote the Bloch’s alternated cubical cycle complex (we use the version of the definition described in §1 of [Han95]). It is defined in the following way (note that we consider cohomological complexes; that forces us to reverse arrows in the usual notation).

One first defines a sequence of groups $Z'_r(X)$ with
\[ Z'_r(X) = \sum_{U \subseteq X \times \mathbb{A}^{-i}} U, \]
where $U$ runs through all integral closed subschemes of $X \times \mathbb{A}^{-i}$ of codimension $r - i$ that intersect faces properly; here ‘faces’ mean subvarieties of $X \times \mathbb{A}^{-i}$ defined by putting some of the last coordinates of $X \times \mathbb{A}^{-i}$ equal to 0 or 1. $Z_r$ is obtained form $Z'_r$ by alteration, see the beginning of this subsection.

The boundaries $Z_{ri}(X) \to Z_{ri+1}(X)$ are defined as
\[ \sum_{0 \leq j \leq -i} (g_{j0} - g_{j1}), \]
g_{jx} are defined as in subsection 1.2.

We have a natural map $Z_r(X) \otimes Z_s(Y) \to Z_{r+s}(X \times Y)$ (as complexes) defined by applying $a_{i+j}$ to the corresponding tensor product of cycles ($i, j$ are the indices of terms; see the text after Lemma 2.28 in [Lev05]).

A more detailed description of $Z_r$ (and the discussion of several other questions relevant for the results of this section) could be found in [Lev05]. The reader is strongly recommended to look at §2.5 and §4.3 loc. cit.

The construction of $H$ uses two facts.

(i) For any connected $P, Q \in SmPrVar$, $\dim Q = r$, we have a natural embedding of complexes $JQ([P], [Q]) \to Z^r(P \times Q)$.

This is obvious from the definition of $Z^r$.

(ii) For any connected $P, Q, R \in SmPrVar$, $\dim R = s$, the partially defined composition $Z^r(P, Q) \times Z^s(Q, R) \to Z^s(P, R)$ (cf. Proposition 4.3 of [Han04]) for Bloch complexes restricted to $JQ(P, Q) \times JQ(Q, R)$ coincides with the map induced by the composition in $JQ$. This is very easy since the composition of morphisms in $JQ$ is exactly the one induced from the composition of Bloch complexes (described above). Note that the composition of morphisms coming from $JQ$ is always well-defined.
Hence sending \([P] \in \text{Obj}\mathcal{J}\mathcal{Q}\) to \((P,0) \in \text{Obj}\mathcal{I}\) and embedding \(\mathcal{J}\mathcal{Q}([P],[Q]) \to \mathcal{Z}^*(P \times Q)\) we obtain a differential graded functor \(G : \mathcal{J}\mathcal{Q} \to \mathcal{I}\). This gives \(H = TrG\).

We note that in Hanamura’s construction one often has to choose distinguished subcomplexes (and modify the choice of elements of Bloch complexes) in order to ’compute’ compositions of arrows in his categories. Yet in the ’image’ of \(H\) this problem never occurs.

### 4.3 \(F\) is a full embedding

We check that \(H\) (and so also \(F\)) is fully faithful.

By part 3 of Remark 3.1.2 it suffices to check that \(H\) induces an isomorphism
\[
\mathcal{H}\mathcal{Q}([P],[Q][i]) \to \mathcal{D}^{op}_{\text{fin}}((P,0),(Q,0)[i])
\]
for all \(P,Q \in \text{SmPrVar}\), \(i \in \mathbb{Z}\). Since in \(\mathcal{D}(k)\) there is Poincare duality (by definition, see also (4.5) of [Han04]), for \(Q\) of pure dimension \(n\) we have
\[
\mathcal{D}^{op}_{\text{fin}}((P,0),(Q,0)[i]) = \mathcal{D}^{op}_{\text{fin}}((P \times Q,0),(pt,n)[i]) = Ch^r(P \times Q, -i).
\]
Here \(Ch^r(P \times Q, -i)\) denotes the rational higher Chow group, the last equality follows from theorems (4.10) and (1.1) of [Han04]. Since the same is true in \(\mathcal{H}\mathcal{Q}\) (see propositions 4.2.3 and 4.2.9 of [Voe00a]; cf. also Proposition 12.1 of [FrS02]), the isomorphism is compatible with the maps of corresponding complexes, we get the claim.

Another way to express the same argument is to say that \(G : \mathcal{J}\mathcal{Q} \to \mathcal{I}\) induces a quasi-isomorphism on morphisms (considered as complexes of abelian groups). This easily implies that \(TrG\) is a full embedding (even in our situation when \(I\) is ’not quite a category’).

### 4.4 Conclusion of the proof

First we check that any object of the full triangulated subcategory \(\mathcal{D}^{op}_{\text{fin}} \subset \mathcal{D}^{op}_{\text{fin}}\) whose objects are ’positive’ diagrams (i.e., those that contain only symbols of the form \((P,r), r \geq 0\) is equivalent to \(\mathcal{H} \otimes \mathbb{Q}\). We should check that any object of \(\mathcal{D}^{op}_{\text{fin}}\) is isomorphic to an object of the form \(H(X), X \in \text{Obj}\mathcal{H}\mathcal{Q}\).

We define the ’zeroth part’ of \(\mathcal{D}^{op}_{\text{fin}}\) as the full triangulated subcategory of \(\mathcal{D}^{op}_{\text{fin}}\) generated by \((P,0)\). We note \(\mathcal{D}^{op}_{\text{fin}}\) is generated by \((P,r), r \geq 0\), as a triangulated category. This is easy to see directly and also follows immediately from property (6) of §1 of [Han99]. Hence it suffices to verify
that any \((P, r), r \geq 0, P \in \text{SmPrVar}\) is isomorphic to a certain object of the 'zeroth part' of \(D_{\text{fin}}^{op}\).

In fact, \((P, r)\) belongs to the triangulated subcategory of \(D_{\text{fin}}^{op}\) generated by \((\mathbb{P}^l) \times P\) for \(0 \leq l \leq r\). It suffices to check that \((P, r)\) is a direct summand of \((P \times \mathbb{P}^r, 0)\), its complement is \((P \times \mathbb{P}^{r-1}, 0)\). First we note that morphisms between 'pure' objects (i.e., between the objects of \(D_{\text{fin}}^{op}\) of the type \((P, r)\)) by definition equal to the morphisms between corresponding Chow motives. The last statement is just a well-known property of Chow motives; it follows easily from the fact that \(\text{Chow}^{eff}\) is a tensor category (note that \(D_{\text{fin}}^{op}\) also is and the tensor multiplications are compatible) and \([\mathbb{P}^r] = [\mathbb{P}^{r-1}] \oplus [\text{pt}][r][2r]\) in \(\text{Chow}^{eff}\) (in the covariant notation).

A similar direct sum statement is verified in §2.3 of [Han04]. The main difference is that Hanamura presented \((P, r)\) as a direct summand of \((P \times (\mathbb{P}^1)^r, 0)\) and does not care about its complement. Since we will idempotent complete \(DM_{gm} \otimes \mathbb{Q}\) in the end of the section, this version also fits our purposes.

Hence we get the equivalence of \(\mathcal{H} \otimes \mathbb{Q}\) with \(D_{\text{fin}}^{op} +\).

Note that \(\mathbb{Q}(1) \in \text{Obj} \mathcal{H} \otimes \mathbb{Q}\) differs from \(\text{pt}(1)\) in \(D_{\text{fin}}^{op} +\) by a shift by [2]; cf. also the remark at the bottom of page 139 of [Han04].

Now we prove that this equivalence can be extended to \(DM_{gm} \otimes \mathbb{Q}\).

The definition of morphisms in \(D_{\text{fin}}^{op}\) immediately implies the cancellation theorem, i.e., \(D_{\text{fin}}^{op}(X, Y) = D_{\text{fin}}^{op}(X(1), Y(1))\). Moreover, our definition of \(-(1)\) on \(\mathcal{H}\) (in §3.3) is easily seen to be compatible the Tate twist on \(D_{\text{fin}}^{op}\) (again, they differ by a shift by [2]).

Hence we can extend \(F\) to a functor \(F' : \mathcal{H}_{gm} \otimes \mathbb{Q} \rightarrow \lim_{\rightarrow -(1)} D_{\text{fin}}^{op} +\); \(F'\) is also a full embedding. It remains to recall that \(DM_{gm} \otimes \mathbb{Q}\) is isomorphic to the idempotent completion of \(\mathcal{H}_{gm} \otimes \mathbb{Q}\) (see part 1 of Remark 3.3.2), whereas \(D^{op}\) is the idempotent completion of \(\lim_{\rightarrow -(1)} D_{\text{fin}}^{op} + = \bigcup_{n>0} D_{\text{fin}}^{op} +(-n)\).

The proof is finished.

Remark 4.4.1. Hanamura defined \(\mathcal{D}(k)\) as a triangulated subcategory of a certain 'infinite' analogue of \(\mathcal{D}_{\text{fin}}(k)\). Yet we do not need this definition for the proof of equivalence (above) since \(\mathcal{D}(k)\) was defined as the idempotent completion of \(\mathcal{D}_{\text{fin}}(k)\); recall that the idempotent completion of a triangulated category is canonical (see [BaS01]).

5 The properties of cubical Suslin complexes

The main result of this section is that the cubical complex \(C(X)\) is quasi-isomorphic (as a complex of presheaves) to the simplicial complex \(\square(X)\) that
was used in [Voe00a]. This fact was mentioned by M. Levine (Theorem 2.25 of [Lev05]) yet no complete proof was given. One of the possible methods of the proof (proposed in [Lev05]) is the use of a bicomplex method. Recall that this method yielded a similar result for motivic cohomology in §4 of [Lev94] and can be adjusted to yield the proof of the statement desired. Yet we use another method here. The reader not interested in the details of the proof should skip this section.

5.1 A certain adjoint functor for the derived category of presheaves

We denote by $\text{PreShv}(\text{SmCor})$ the category of presheaves (of abelian groups) on $\text{SmCor}$, by $D^{-}(\text{PreShv}(\text{SmCor}))$ the derived category of $\text{PreShv}(\text{SmCor})$ (complexes are bounded from above), by $\text{DPM}^{\text{eff}}$ we denote a full subcategory of $D^{-}(\text{PreShv}(\text{SmCor}))$ whose objects are complexes with homotopy invariant cohomology.

**Lemma 5.1.1.** $C(P) \in \text{DPM}^{\text{eff}}$.

**Proof.** The scheme of the proof is the same as for Proposition 3.6 in [Voe00b]. First we check that for $Y \in \text{SmVar}$ and $P \in \text{SmPrVar}$ the maps $i_0^*, i_1^* : C(P)(Y \times \mathbb{A}) \to C(P)(Y)$ are homotopic; here $i_0^*, i_1^*$ are induced by the embeddings $i_x : Y \times \{x\} \to Y \times \mathbb{A}$, $x = 0, 1$. We consider the maps $p r_i : C'(P)^i(Y) \to C'(P)^i(Y \times \mathbb{A})$ induced by the projections $Y \times \mathbb{A} \to Y$. Also consider the maps $h_i^i : C'(P)^i(Y \times \mathbb{A}) \to C'(P)^{i-1}(Y)$ induced by isomorphisms $Y \times \mathbb{A} \times \mathbb{A}^{-i} \cong Y \times \mathbb{A}^{-i+1}$ (we put the $\mathbb{A}$ multiplier at the first coordinate of the right hand side), and $h_i : C(P)^i(Y \times \mathbb{A}) \to C(P)^{i-1}(Y)$, $h_i = h_i^i - pr_{i-1} \circ i_0^*$. We have

$$\delta_{i+1}h_i + h_{i+1}\delta_i = (i_1^* - i_0^*)_i,$$

i.e., $h_i$ gives the homotopy needed. Then $i_0^*, i_1^*$ induce coinciding maps on cohomology. Let $Y = U \times \mathbb{A}$, $U \in \text{SmVar}$. We consider the morphism $H = id_U \times \mu : U \times \mathbb{A}^2 \to U \times \mathbb{A}$, where $\mu$ is given by multiplication. Since the maps induced by $H \circ i_0$ and $H \circ i_1$ on the cohomology of $C(P)(Y)$ coincide, the composition $U \times \mathbb{A} \to U \overset{id_U \times i_0}{\to} U \times \mathbb{A}$ induces an isomorphism on the cohomology of $C(P)(U \times \mathbb{A})$ for any $U \in \text{SmVar}$. Hence the cohomology presheaves of $C(P)$ are homotopy invariant. 

Now we formulate an analogue of Proposition 3.2.3 in [Voe00a]. By $(F)$ we denote a complex concentrated in degree 0 whose non-zero term is $F$.  

33
Proposition 5.1.2. 1. There exists an exact functor $R : D^-(\text{PreShv}(\text{SmCor})) \rightarrow \text{DM}^{eff}$ right adjoint to the embedding $\text{DM}^{eff} \rightarrow D^-(\text{PreShv}(\text{SmCor}))$. Besides $R((F)) \cong \underline{C}(F)$ (see the definition of $\underline{C}(F)$ in §3.2 [Voe00a]).

2. In $D^-(\text{PreShv}(\text{SmCor}))$ we have $R(\underline{C}(L(P))) \cong C(P) \cong R(L(P))$.

Proof. 1. The proof is similar to the proof of existence of the projection $R_C : D^-(\text{Shv}(\text{SmCor})) \rightarrow \text{DM}^{eff}$ in 3.2 of [Voe00a]. We consider the localising subcategory $\mathcal{A}$ in $D^-(\text{PreShv}(\text{SmCor}))$ that is generated by all complexes $L(X \times \mathcal{A}) \rightarrow L(X)$ for $X \in \text{SmVar}$. As in [Voe00a] we have $D^-(\text{PreShv}(\text{SmCor}))/\mathcal{A} \cong \text{DM}^{eff}$ (cf. Theorem 9.32 of [MVW06]).

Now as in the proof of Proposition 3.2.3 in [Voe00a] we should verify the following statements.

1. For any $F \in \text{PreShv}(\text{SmCor})$ the natural morphism $\underline{C}(F) \rightarrow (F)$ is an isomorphism in $D^-(\text{PreShv}(\text{SmCor}))/\mathcal{A}$.

2. For all $T \in \text{DM}^{eff}$ and $B \in \mathcal{A}$ we have $D^-(\text{PreShv}(\text{SmCor}))(B, T) = 0$.

The proof of the first assertion may be copied word for word from the similar statement in 3.2.3 of [Voe00a]. This was noted in the proof of Theorem 3.2.6 of [Voe00a].

As in [Voe00a], for the second assertion we should check for any $X \in \text{SmVar}$ the bijectivity of the map $D^-(\text{PreShv}(\text{SmCor}))((L(X)), T) \rightarrow D^-(\text{PreShv}(\text{SmCor}))(L(X \times \mathcal{A}), T)$ induced by the projection $X \times \mathcal{A} \rightarrow X$. Since representable presheaves are projective in $\text{PreShv}(\text{SmCor})$ (obvious from Yoneda’s lemma, cf. 2.7 in [MVW06]), this follows immediately from the homotopy invariance of the cohomology of $\underline{C}(F)$.

2. From part 2 of Lemma 5.1.3 below we obtain that the morphism $(L(P)) \rightarrow C(P)$ induces an isomorphism $R((L(P))) \cong R(C(P))$ in the category $D^-(\text{PreShv}(\text{SmCor}))$. Using assertion 1 we obtain that the map $C(P) \rightarrow (L(P))$ induces an isomorphism $R((L(P))) \cong R(C(P))$. Since $R$ is right adjoint to an embedding of categories, it remains to note that $C(L(P)), C(P) \in \text{DM}^{eff}$. □

Lemma 5.1.3. 1. $R(C^j(P)) = 0$ for $j < 0$.

2. The morphism $i_P : (L(P)) \rightarrow C(P)$ induces an isomorphism $R((L(P))) \cong R(C(P))$ in $D^-(\text{PreShv}(\text{SmCor}))$.

Proof. 1. We consider the same maps $h_i : C(P)^i(Y \times \mathcal{A}) \rightarrow C(P)^{i-1}(Y)$ as in the proof of Lemma 5.1.1. Obviously $h_i$ is epimorphic, besides $	ext{Ker} h_i \cong C(P)^i(Y)$. We obtain an exact sequence $0 \rightarrow C(P)^i(Y) \rightarrow C(P)^i(Y \times \mathcal{A}) \rightarrow C(P)^{i-1}(Y) \rightarrow 0$. (9)
We prove the assertion by induction on \( j \). The case \( j = -1 \) follows immediately from (9) applied for the case \( i = 0 \). If \( R(C^j(P)) = 0 \) for \( j = m \), then \( R \) maps \( C(P)^m \) and \( C^m(P)^m \) to 0, where \( C^m(P)^m(Y) = C(P)^m(Y \times A) \). Applying (9) for \( i = m \) we obtain \( R(C(P)^m-1) = 0 \) (recall that \( R \) is an exact functor).

2. Follows from assertion 1 immediately. \( \square \)

Now we recall (Theorem 8.1 of \cite{FrV00}) that the cohomology groups of \( C(L(P))(Y) \) are exactly \( A_{0,-i}(Y,P) \). Hence we completed the proof of Proposition 1.2.2.

5.2 Proof of Proposition 1.3.1

**Lemma 5.2.1.** For all \( i \in \mathbb{Z}, P,Y \in SmPrVar \), the obvious homomorphism

\[
K^-(Shv(SmCor))((L(Y)), C(P)[i]) \rightarrow D^-(Shv(SmCor))((L(Y)), C(P)[i])
\]

is bijective.

**Proof.** By definition the homomorphism considered in the map from the cohomology of \( C(P) = C^c(P) \) into its hypercohomology. By Theorem 8.1 of \cite{FrV00} for \( C(P)(= C^c(P)) \) the corresponding map is bijective. Hence the assertion follows from \( C(P) \cong C(P) \) in \( D^-(Preshv(SmCor)) \). \( \square \)

**Proposition 5.2.2.** \( i_P : (L(P)) \rightarrow C(P) \) induces an isomorphism \( RC((L(P))) \cong C(P) \) in \( DM^e_{eff} \).

**Proof.** Literally repeating the argument of the proof of part 1 of Lemma 5.1.3 we obtain \( RC(C^j(P)) = 0 \) for \( j < 0 \). Therefore \( RC((L(P))) \cong RC(C(P)) \). It remains to note that \( C(P) \in ObjDM^e_{eff} \). \( \square \)

Now we finish the proof of Proposition 1.3.1 The assignment \( g \rightarrow G = (g^! \) defines a homomorphism

\[
K^-(Shv(SmCor))((L(Y)), C(P)[i]) \rightarrow K^-(Shv(SmCor))(C(Y), C(P)[i]).
\]

Hence it is sufficient to verify that the map

\[
DM^e_{eff}(RC((L(Y))), C(P)[i]) \rightarrow DM^e_{eff}(C(Y), C(P)[i])
\]

induced by this homomorphism coincides with the homomorphism induced by the map \( i_{P*} : RC(L(P)) \cong RC((C(Y))) \). Since \( G \circ i_{P*} = g \), we are done.
6 Truncation functors, the length of motives, and $K_0(DM_{gm}^{eff})$

In subsection 6.1 using the canonical filtration of the (cubical) Suslin complex we define the truncation functors $t_N$. These functors are new though certain very partial cases were (essentially) considered in [GiS96] and [GN-A02] (there another approaches were used).

The target of $t_0$ is just $K^b(Corr_{rat})$ (complexes of rational correspondences, see 1.1). In subsection 6.3 we prove that $t_0$ extends to $t : DM_{gm}^{eff} \to K^b(C'how^{eff})$ and to $t_{gm} : DM_{gm} \to K^b(C'how)$. In 6.4 we prove that $t$ induces an isomorphism $K_0(DM_{gm}^{eff}) \cong K_0(C'how^{eff})$ thus answering the question of 3.2.4 of [GiS96]. In Corollary 6.4.3 we extend this result to an isomorphism $K_0(DM_{gm}) \cong K_0(C'how)$.

The functors $t$ (Proposition 6.3.1), $t_{gm}$ (Remark 6.3.2), and all $t_N$ (see Theorem 6.2.1) are conservative. $t$ induces a natural functor $t_{num} : DM_{gm}^{eff} \to K^b(Mot_{num}^{eff})$. Over a finite field $t_{num}\mathbb{Q}$ is (conjecturally) an equivalence, cf. Remark 5.2.2.

We define the length of a motif: stupid length in 6.2, fine and rational length in 6.3. The stupid length is not less than the fine length, the fine length is not less than the rational one. We prove (Theorem 6.2.1) that motives of smooth varieties of dimension $N$ have stupid length $\leq N$; besides $t_N(X)$ contains all information on motives of length $\leq N$. The length of a motif is a natural motivic analogue of the length of weight filtration for a mixed Hodge structure.

For a smooth quasi-projective variety $X$ we calculate $m^{-1}(M_{gm}^{c}(X))$ explicitly (in 6.5). Using this result we prove that the weight complex of Gillet and Soulé for a smooth quasi-projective variety $X$ can be described as $t_0(m^{-1}(M_{gm}^{c}(X)))$. Next we recall the cdh-topology of Voevodsky and prove this statement for arbitrary $X \in Var$ (see 6.6). Besides, $t_0(m^{-1}(M_{gm}(X)))$ essentially coincides with the functor $h$ described in Theorem 5.10 of [GN-A02].

In the next section we will verify that the weight filtration of 'standard' realizations is closely related to $t_N$; the rational length of a motif coincides with the (appropriately defined) length of the weight filtration of its singular realization.

6.1 Truncation functors of level $N$

For $N \geq 0$ we denote the $-N$-th canonical filtration of $C(P)$ as a complex of presheaves (i.e., $\cdots \to 0 \to C^{-N}(P)/d_P C^{-N-1}(P) \to C^{-N+1}(P) \to \cdots \to C^{0}(P) \to 0 \to \cdots$) by $C_N(P)$. 

36
We denote by \( J_N \) the following differential graded category. Its objects are the symbols \([P]\) for \( P \in \text{SmPrVar} \), whereas \( J_N([P],[Q])^i = C_N^i(Q)(P) \). The composition of morphisms is defined similarly to those in \( J \). For morphisms in \( J_N \) presented by \( g \in C^i(Q)(P), h \in C^j(R)(Q) \), we define their composition as the morphism represented by \( h^i(g) \) for \( i + j \geq -N \) and 0 for \( i + j < -N \). Note that for \( i + j = -N \) we take the class of \( h^i(g) \) mod \( d_RC^{-N-1}(R)(P) \); for \( i = -N, j = 0 \), and vice versa, \( g \) is only defined up to an element of \( d_RC^{-N-1}(Q)(P) \) (resp. \( h \) is defined up to an element of \( d_RC^{-N-1}(R)(Q) \)) yet the composition is well-defined. The boundary on morphisms is also defined as in \( J \), i.e., for \( g \in J_N(P,Q) \) we define \( \delta g = d_Q g \). Certainly, all \( J_N \) are negative (i.e., there are no morphisms of degree \( >0 \)).

We have an obvious functor \( J \to J_N \). As noted in Remark \[2.3.3\] this gives canonically a functor \( t_N : \mathcal{H} \to Tr(J_N) \). We denote \( Tr(J_N) = Tr(J_N) \) by \( \mathcal{H}_N \); note that \( \mathcal{H}_0 \) is precisely \( K^b(\text{Corr}_{\text{rat}}) \).

For any \( m \leq N \) we also have an obvious functor \( J_N \to J_m \). It induces a functor \( t_{N,m} : \mathcal{H}_N \to \mathcal{H}_m \) such that \( t_m = t_{N,m} \circ t_N \).

Certainly, one can give a description of \( \mathcal{H}_N \) that is similar to the description of \( \mathcal{H} \) given in subsection \[2.3\]. Hence objects of \( \mathcal{H}_N \) can be represented as certain \( (P^i, f_{ij} \in C^{N-i-j-1}(P^i)(P^j), i < j \leq i + N + 1) \), the morphisms between \( (P^i, f_{ij}) \) and \( (P^i', f_{ij}' \) ) are represented by certain \( g_{ij} \in C^{-j}(P^j, P^i), i < j \leq i + N \), etc. The functor \( t_N \) 'forgets' all elements of \( C^m([P],[Q]) \) for \( P,Q \in \text{SmPrVar} \), \( m < -N \), and factorizes \( C^{-N}([P],[Q]) \) modulo coboundaries. In particular, for \( N = 0 \) we get ordinary complexes over \( \text{Corr}_{\text{rat}} \).

### 6.2 The 'stupid' length of motives (in \( DM^s \)); conservativity of \( t_0 \)

It was proved in \[\text{Yoe00a}\] that the functor \( M_{gm} \) gives a full embedding of \( \text{Corr}_{\text{rat}} \to DM_{eff}^s \). In this subsection we prove a natural generalization of this statement.

We will say that \( P = (P^l, f_{ij}) \in \text{Obj} \mathcal{H}^f \) is concentrated in degrees \([l,m]\), \( l, m \in \mathbb{Z} \), if \( P^l = 0 \) for \( i < l \) and \( i > m \). We denote the corresponding additive set of objects of \( \mathcal{H}^f \) by \( \mathcal{H}^f_{[a,b]} \). We denote by \( \mathcal{H}^f_{[a,b]} \) the objects of \( \mathcal{H}^f \) that are isomorphic to those coming from \( \mathcal{H}^f_{[a,b]} \).

Obviously (from the description of distinguished triangles in \( Tr(C) \) for any differential graded \( D \) if \( A \to B \to C \to A[1] \) is a distinguished triangle, \( A, C \in \mathcal{H}^f_{[a,b]} \), then \( B \in \mathcal{H}^f_{[a,b]} \).

**Theorem 6.2.1.** 1. For any smooth variety \( Y/k \) of dimension \( \leq N \) we have \( m^{-1}(M_{gm}(Y)) \in \mathcal{H}^f_{[0,N]} \).
2. For any smooth variety $Y/k$ of dimension $\leq N$ we have $m^{-1}(M_{gm}(Y)) \in \mathcal{F}_{[-N,0]}$.

3. If $A \in \mathcal{F}_{[a,b]}$, $B \in \mathcal{F}_{[c,d]}$, $N \geq d - a$, $N \geq 0$, then $\mathcal{F}(A,B) \cong \mathcal{F}_N(t_N(A), t_N(B))$.

4. If $s \in \mathcal{F}(X,X)$ for $X \in Obj \mathcal{F}$ is an idempotent and $t_0(s) = 0$ then $s = 0$.

5. $t_0$ is conservative, i.e., for $Y \in \mathcal{F}$ we have $Y = 0 \iff t_0(Y) = 0$.

6. $f : A \to B$ is an isomorphism if and only if $t_0(f)$ is.

**Proof.** 1. Obviously, the statement is valid for smooth projective $Y$. We prove the general statement by induction on dimension.

By the projective bundle theorem (see Proposition 3.5.3 of [Voe00a]) for any $c \geq 0$ we have a canonical isomorphism $\mathbb{P}^c \cong \oplus_{0 \leq i \leq c} \mathbb{Z}(i)[2i]$. Hence $\mathbb{Z}(c)[2c]$ can be represented as a cone of the natural map $M_{gm}(\mathbb{P}^{c-1}) \to M_{gm}(\mathbb{P}^c)$. Therefore $\mathbb{Z}(c)[2c] \in m(\mathcal{F}_{[-1,0]}).

One can easily show that for any $X \in \mathcal{F}_{[e,f]}$, $e,f \in \mathbb{Z}$, $e > 0$ we have $X(c)[2c] \in \mathcal{F}_{[e-1,f]}$ (here we consider Voevodsky’s Tate twist). Indeed, if $X$ can be decomposed into a Postnikov tower whose ‘factors’ are $P^i$ (the terms of the weight complex $t(X)$) then $X(c)[2c]$ can be decomposed into a Postnikov tower whose ‘factors’ are $P^i(c)[2c]$; since $t$ is an exact functor, we obtain that $t(X(c)[2c])$ is homotopy equivalent to a complex concentrated in degrees $[e-1,f]$.

We recall the Gysin distinguished triangle (see Proposition 3.5.4 of [Voe00a]).

For a closed embedding $Z \to X$, $Z$ is everywhere of codimension $c$, it has the form

$$M_{gm}(X - Z) \to M_{gm}(X) \to M_{gm}(Z)[c][2c] \to M_{gm}(X - Z)[1].$$

Suppose that the assertion is always fulfilled for $\dim Y = N' < N$.

Let $X/k$ be a smooth quasi-projective variety. Since $k$ admits resolution of singularities, $X$ can be represented as a complement to a $P \in SmPrVar$ of a divisor with normal crossings $\cup_{i \geq 0} Q^i$. Then using (10) one proves by induction on $j$ that the assertion is valid for all $Y^j = P \setminus (\cup_{0 \leq i \leq j} Q^i)$. To this end we check by the inductive assumption for $j \geq 0$ that

$$M_{gm}(P \setminus (\cup_{0 \leq i \leq j} Q^i) \setminus (P \setminus (\cup_{0 \leq i \leq j+1} Q^i))) = M_{gm}(Q^{i+1} \setminus (\cup_{0 \leq i \leq j} Q^i)) \in m(\mathcal{F}_{[0,N-1]}).$$

Hence $M_{gm}(X) \in m(\mathcal{F}_{[0,N]}).$

If $X$ is not quasi-projective we can still choose closed $Z \subset X$ (of codimension > 0) such that $X - Z$ is quasi-projective. Hence the assertion follows from the inductive assumption by applying (10).

38
2. The proof is similar to those of the previous part. The difference is that we don’t have to twist and should use the distinguished triangle of Proposition 4.1.5 of [Voe00a]:

\[ M_g^e(Z) \rightarrow M_g^e(X) \rightarrow M_{gm}(X - Z) \rightarrow M_g^e(Z)[1] \]  

instead of (10).

3. We can assume (by increasing \( d \) if needed) that \( N = d - a \).

Let \( A = (P^i, f_{ij}) \), \( B = (P^q, f'_{ij}) \). As we have seen in subsection 2.5 any \( g \in \mathcal{S}(A, B) \) is given by a certain set of \( g_{ij} \in C_{i-j}^t(P^{ij})(P^{i}) \). The same is valid for \( h = (h_{ij}) \in \mathcal{S}_N(t_N(A), t_N(B)) \); the only difference is that \( h_{ad} \) is given modulo \( d_{P^d}C^{-N-1}(P^{ad})(P^{a}) \). Both \( (g_{ij}) \) and \( (h_{ij}) \) should satisfy the conditions

\[
\delta_{P^i}^{r-1}(m_{ij}) + \sum_{j \geq t \geq i} f_{ij}^{r-1}(m_{ad}) = \sum_{j \geq t \geq i} m_{ij}^{r-1}(f_{it}) \quad \forall i, j \in \mathbb{Z}. \tag{12}
\]

First we check surjectivity. We recall that the conditions (12) for \( g \) depend only on \( g_{ij} \) for \( (i, j) \neq (a, d) \) and on \( d_{P^d}g_{ad} \). Hence if \( (h_{ij}) \) satisfies the conditions (12) then \( h = t_N(r) \), where \( r_{ij} = h_{ij} \) for all \( (i, j) \neq (a, d) \), \( r_{ad} \) is an arbitrary element of \( C^{-N}(P^{ad})(P^{a}) \) satisfying \( r_{ad} \mod d_{P^d}C^{-N-1}(P^{ad})(P^{a}) = h_{ad} \).

Now we check injectivity. Let \( t_N(g) = 0 \) for \( g = (g_{ij}) \in \mathcal{S}(A, B) \). Note that \( C_N(P) \) is a factor-complex of \( C(P) \) for any \( P \in SmPrVar \). Hence similarly to subsection 2.5 one can easily check that there exist \( l_{ij} \in C_{i-j}^t(P^{ij})(P^{i}) \), \( i \leq j \), such that

\[
g_{ij} = \delta_{P^i}^{r-1}l_{ij} + \sum_{i \leq r \leq j} \left( f_{i}^{r-1}(l_{ir}) + l_{ij}^{r-1}(f_{ir}) \right) \tag{13}
\]

for all \((i, j) \neq (a, d)\), for \( i = a, j = d \) the equality (13) is fulfilled modulo \( d_{P^d}q \) for some \( q \in C_{i-j}^t(P^{ad})(P^{a}) \). We consider \((l'_{ij})\), where \( l'_{ij} = l_{ij} + q \). Obviously, if we replace \((l_{ij})\) by \((l'_{ij})\) then (13) would be fulfilled for all \( i, j \). Therefore \( g = 0 \in \mathcal{S}(A, B) \).

4. Let \( X = (P^i, f_{ij}) \) be as in subsection 2.5; let \( s \) be given by a set of \( s_{ij} \in \mathcal{J}^{i-j}([P^i], [P^{ij}]) \), \( i \leq j \); \( (s_{ij}) \) are defined up to a homotopy of the sort described in 2.5. \( t_0(s) \) is homotopic to zero. Since this homotopy can be represented by a set of \( m_i \in SmCor(P^i, P^{i-1}) = \mathcal{J}^{0}([P^i], [P^{i-1}]) \), we can lift this homotopy to \( \mathcal{S} \). This means that we take \( l_{ij} = m_i \) for \( j = i - 1 \), \( l_{ij} = 0 \) for \( j \neq i - 1 \), where \( l \) is as in (3); this allows us to assume that \( s_{ii} = 0 \). Next, since \( s^2 = s \) in \( \mathcal{S} \), we have \( s^n = s \) for any \( n > 0 \). Now note that all degrees of components of \( s^n \) are \( \leq -n \). Hence \( s^r = 0 \) if \( X \in \mathcal{S}^{a,b} \) for \( r > b - a \).
5. Immediate from assertion 4 applied to $X = Y$ and $s = id_Y$.

6. Follows immediately from assertion 5 (recall that a morphism is an isomorphism if and only if its cone is zero).

In fact, for a smooth quasi-projective $X$ one can compute $M_{gm}^c(X)$ explicitly (see Proposition 6.3.1 below).

We say that $X \in \mathcal{H}$ has stupid length $\leq N$ if for some $l \in \mathbb{Z}, m \leq l + N$, the motif $X \in H_{[l,m]}$. We will define the fine length of a motif below.

**Remark 6.2.2.** 1. In fact, surjectivity (but not injectivity) in part 3 is also valid for $d - a = N$. We should choose $r_{ad}, r_{a+1,d}$, and $r_{a,d-1}$; the classes of $r_{a+1,d}$ and $r_{a,d-1}$ modulo coboundaries are fixed. This choice affects the equality (12) only for $i = a, j = d$. Note also that this equality only depends on $p_{rad}$. One can choose arbitrary values of $r_{a+1,d}$ and $r_{a,d-1}$ in the corresponding classes.

Then the equality (12) with $r_{ad} = 0$ will be satisfied modulo $d_{pq}q$ for some $q \in C^{-N-1}(P^n)(P^n)$. Therefore if we take $r_{ad} = q$ then $t_N(r) = h$.

2. Let $A \in H_{[a,b]}, B \in H_{[c,d]}, N + 1 \geq d - a, N \geq 0$. Then one can check that $A \cong B$ iff $t_N(A) \cong t_N(B)$.

Indeed, if $f : A \to B$ is an isomorphism then $t_N(f)$ also is.

Conversely, let $f_N : t_N(A) \to t_N(B)$ be an isomorphism. Then, as was noted above, there exists an $f \in H(A, B)$ such that $f_N = t_N(f)$ (if is not necessarily unique). Since $t_N(F)$ is an isomorphism, $t_0(f) = t_N(t_0(f))$ also is. From part 6 of Theorem 6.2.1 we obtain that $f$ gives an isomorphism $A \cong B$.

It follows immediately that two objects $A, B \in \mathcal{H}$ of stupid length $\leq N + 1$ are isomorphic if and only if $t_N(A) \cong t_N(B)$.

3. One could define $H_{N,[0,N]} \subset H_N$ similarly to $H_{[0,N]}$. Then $t_N$ would give an equivalence of additive categories $H_{[0,N]} \to H_{N,[0,N]}$. Indeed, this restriction of $t_N$ is surjective on objects; it is an embedding of categories by part 3 of Theorem 6.2.1.

6.3 **Fine length of a motif (in $DM_{gm}^{eff}$); conservativity of the weight complex functor $t : DM_{gm}^{eff} \to K^b(Chow^{eff})$**

One can check (using the method of the proof of Proposition 6.4.1 below) that the stupid length of a motif $M \in ObjDM^s$ coincides with the length of $t_0(M) \in K^b(Corr_{rad})$. Yet replacing $K^b(Corr_{rad})$ by $K^b(Chow^{eff})$ one can obtain a more interesting invariant which will be defined on the whole $ObjDM_{gm}^{eff}$.
Proposition 6.3.1. 1. $t_0$ can be extended to an exact functor $t : D^{eff}_{gm} 	o K^b(Chow^{eff})$, where $D^{eff}_{gm}$ is the idempotent completion of $\mathcal{H}$.

2. $t$ is conservative.

Proof. 1. By the main result of [BaS01], $t_0$ can be canonically extended to an exact functor from $D^{eff}_{gm}$ to the idempotent completion of $K^b(Corr_{rat})$. It remains to note that the idempotent completion of $K^b(Corr_{rat})$ is exactly $K^b(Chow^{eff})$ (see, for example, Corollary 2.12 of [BaS01]).

2. Immediate from part 4 of Theorem 6.2.1.

Remark 6.3.2. 1. Exactly the same arguments yield that there exists a functor $t_0 \otimes Q : \mathcal{H} \otimes Q \to K^b(Corr_{rat} \otimes Q)$ that can be extended to a conservative $t_Q : D^{eff}_{gm} \otimes Q \to K^b(Chow^{eff} \otimes Q)$.

2. Since $\mathcal{H} \cong DM^\ast$, we have $D^{eff}_{gm} \cong DM^{eff}_{gm}$. For this reason we will usually identify these categories.

3. As was shown in §3.3, $DM_{gm}$ is isomorphic to the idempotent completion of a certain triangulated category $\mathcal{H}^\prime_{gm}$ that has a differential graded enhancement. Now, note that the complex $J_{gm}(P(i)[2i], Q(j)[2j])$ (in the notation of part 2 of Remark 3.3.2) is acyclic in positive degrees for any $P, Q \in SmVar, i, j \in \mathbb{Z}$ (indeed, since the Tate twist is invertible, we can assume $i, j \geq 0$). Hence (replacing $\mathcal{H}_{gm}$ by an equivalent category again) we obtain that $DM_{gm}$ is equivalent to $Tr(I)$ for a certain negative differential graded $I$ (see part 2 of Remark 2.7.1).

Now recall that $Chow^{eff}$ is a tensor category and the functor $\otimes \mathbb{Z}(1)[2] : Chow^{eff} \to Chow^{eff}$ is fully faithful. $Chow$ is usually defined as the ‘union’ of $Chow^{eff}(-i)[-2i]$, whereas each $Chow^{eff}(-i)[-2i]$ is isomorphic to $Chow^{eff}$, i.e., $Chow = \lim_{\longrightarrow \mathbb{Z}(1)[2]} Chow^{eff}$. We obtain that $HI \subset Chow$. It follows that one can (essentially) extend $t$ to an exact functor $t_{gm} : D^{eff}_{gm} \to K^b(Chow)$. Since $t$ is conservative, $t_{gm}$ also is.

4. Composing $t$ (or $t_Q$) with the natural functor $Chow^{eff} \to Mot^{eff}_{num}$ (resp. $Chow^{eff} \otimes Q \to Mot^{eff}_{num} \otimes Q$) one gets a functor $t_{num} : D^{eff}_{gm} \to K^b(Mot^{eff}_{num})$ (resp. $t_{num} \otimes Q : D^{eff}_{gm} \otimes Q \to K^b(Mot^{eff}_{num} \otimes Q)$). These functors can be easily extended to functors $D^{eff}_{gm} \to K^b(Mot_{num})$ and $D^{eff}_{gm} \otimes Q \to K^b(Mot_{num} \otimes Q)$. Here $Mot_{num}$ (and $Mot^{eff}_{num}$) denotes the category of (effective) numerical motives; note that $Mot_{num}$ is an abelian category (see [Jan92]). Yet in order to obtain the ‘correct’ structure of $K^b(Mot_{num})$ (i.e., those compatible with ‘standard’ realizations) one needs Künneth projectors for numerical motives; currently they are known to exist only over a finite field (see [S3.3]). Moreover, one cannot prove that $t_{num} \otimes Q$ is conservative without assuming certain ‘standard’ conjectures (cf. Proposition 8.3.1). See also part 2 of Remark 8.3.2 below for further discussion of the case of a finite $k$. 

41
Note also: if numerical equivalence of cycles coincides with homological equivalence (a standard conjecture!) then the cohomology of $t_{num,\mathbb{Q}}(X)$ computes the (pure) weight factors of étale (and singular) cohomology of $X$; see subsection 7.4 below. This generalizes to (weight complexes of) motives.

Remark 3.1.6 of [GiS96].

Definition 6.3.3. 1. For $M \in Obj\mathcal{DM}^{eff}$ we write $M \in \mathcal{DM}^{eff}_{gm}[a,b]$ if $t(M) \cong W$ for a complex $W$ of Chow motives concentrated in degrees $[a,b]$.

2. We define the fine length of $M$ as the smallest difference $b-a$ such that $M \in \mathcal{DM}^{eff}_{gm}[a,b]$.

3. The rational length of a motif $M$ is the length of $t(M)\otimes \mathbb{Q} \in K^b(Chow^{eff}\mathbb{Q})$ ($Chow^{eff}\mathbb{Q}$ is the idempotent completion of $Chow^{eff}\otimes \mathbb{Q}$!).

Obviously, the fine length of $M \in Obj\mathcal{DM}^s$ is not greater than its stupid length and not less than its rational length. Note also that the fine length of $\mathbb{Z}(n)$ is 0. Besides, we also have the sets $\mathcal{DM}^{eff}_{gm}[a,b],\mathbb{Q} \subset Obj\mathcal{DM}^{eff}_{gm}\mathbb{Q}$ for each $a \leq b \in \mathbb{Z}$.

The length of a motif is a natural motivic analogue of the length of weight filtration of a mixed Hodge structure or of a geometric representation (i.e., of a representation coming from the étale cohomology of a variety). Note that even the stupid length of the motif of a smooth variety is not larger than its dimension; this is a motivic analogue of the corresponding statement for the weights of singular and étale cohomology.

The results of the next section along with Proposition 6.4.1 easily imply (see subsection 7.4) that the length of the weight filtration of the singular or étale cohomology of a motif $M$ is not greater than the fine length of $M$. Moreover, the standard conjectures imply that $M \in \mathcal{DM}^{eff}_{gm}[a,b],\mathbb{Q} \iff$ for any $l$ the weights of $H^l(M)$ (singular or étale cohomology) lie between $l+a$ and $l+b$ (see §7.4 below).

6.4 The study of $K_0(\mathcal{DM}^{eff}_{gm})$ and $K_0(\mathcal{DM}_{gm})$

We recall some standard definitions (cf. 3.2.1 of [GiS96]). We define the Grothendieck group $K_0(Chow^{eff})$ as the Abelian group whose generators are of the form $[A]$, $A \in ObjChow^{eff}$; the relations are $[C] = [A] + [B]$ for $C \cong A \oplus B \in ObjChow^{eff}$. Note that $A \oplus 0 \cong A$ implies $[A] = [B]$ if $A \cong B$. We use the same definition for $K_0(Chow)$.

The $K_0$-group of a triangulated category $T$ is defined as the Abelian group whose generators are $[t]$, $t \in ObjT$; if $A \to B \to C \to A[1]$ is a distinguished triangle then $[B] = [A] + [C]$. Note that this also immediately implies $[A] = [B]$ if $A \cong B$.  

42
The existence of $t$ allows us to calculate $K_0(DM_{gm}^{eff})$ easily. To this end we prove the following statement.

**Proposition 6.4.1.** For $X \in \text{Obj}DM_{gm}^{eff}$ if $X \in DM_{gm}^{eff}[a,b]$ then $X$ is a direct summand of some $X' \in \mathcal{F}_{[a,b]}$.

**Proof.** The proof is similar (and generalizes) those of part 4 of Theorem 6.2.1. Suppose that $X$ is a direct summand of an object $Y = (P^i, f_{ij})$ of $\mathcal{F}$ of length $t$; $X$ is given by an idempotent endomorphism $s = (s_{ij})$ of $Y$. It suffices to verify that $Y$ is a direct summand of $X' = Y_{[a,b]}$ (see Proposition 2.6.1).

Similarly to the proof of part 4 of Theorem 6.2.1, we can assume that $s_{ii} = 0$ for $i > b$ and $i < a$. Indeed, $s_{ii} = 0$ is 'homotopic to 0 outside of $[a,b]'$, whereas we can alter $s_{ii}$ by $f_{i-1i}(l_{ii-1}) + l_{i1i}(f_{ii1})$ for any set of $l_{kk1} \in C^0(P^k, P^{k-1})$ (see (6)).

Again we have $s = s^n$ for any $n$. If we replace $s$ by $s^{r+1}$ we easily obtain that $s_{ij} = 0$ for $i > b, j > b$ and $i < a, j < a$.

Obviously, it suffices to check that (for the new choice of $s$):

1.) Arrows $(s_{ij}, a \leq i \leq b)$ give a morphism $s' \in \mathcal{F}(Y_{[a,b]}, Y)$.
2.) $(s_{ij}, a \leq j \leq b)$ give a morphism $s'' \in \mathcal{F}(Y, Y_{[a,b]})$.
3.) $s = s's'$ (in $\mathcal{F}$).

For 1.): We have to check all equalities (5) for $s'$. Both sides of (5) belong to $J^{j-i+1}([P^i], [P^j])$ for some $i, j, a \leq i \leq b$. Since the components of $s'$ are taken from $s$, we only have to compare the differences for both sides for $i, j \geq a$ (for other values of $i, j$ both sides are zero for $s'$). The only summands in (5) for $i, j$ that distinguish $s$ from $s'$ are those of the form $s_{ij}^{j-i+1}(f_{id})$ for $l > b$. Yet in these cases $s_{ij} = 0$ by our assumption.

2.) This is proved similarly.

3.) In $J'$ we have $s^2 = s's'' + (s'' + s')d + d(s'' + s') + d^2$, where the components of $d$ are morphisms in $J([P^i], [P^j])$ for $i < a, j > b$. It remains to note that all (possible) degrees of arrows in $(s'' + s')d + (s' + s)d$ are positive and $d^2 = 0$.

**Theorem 6.4.2.** $t$ induces an isomorphism $K_0(DM_{gm}^{eff}) \cong K_0(\text{Chow}^{eff})$.

**Proof.** Since $t$ is an exact functor, it gives an abelian group homomorphism $a: K_0(DM_{gm}^{eff}) \rightarrow K_0(K^b(\text{Chow}^{eff}))$. By Lemma 3 of 3.2.1 of [GIS96], there is a natural isomorphism $b: K_0(K^b(\text{Chow}^{eff})) \rightarrow K_0(\text{Chow}^{eff})$. The embedding $i: \text{Chow}^{eff} \rightarrow DM_{gm}^{eff}$ (see Proposition 2.1.4 of [Voe00a]) gives a homomorphism $c: K_0(\text{Chow}^{eff}) \rightarrow K_0(DM_{gm}^{eff})$. The definitions of $a, b, c$ imply immediately that $b \circ a \circ c = id_{K_0(\text{Chow}^{eff})}$. Hence $a$ is surjective, $c$ is injective.
It remains to verify that $c$ is surjective.

We claim that if $t(X) = P^i \to P^{i+1} \to \cdots \to P^j, P^i \in \text{ObjChow}^{\text{eff}}$, then the class $[X] \in K_0(DM_{gm}^{\text{eff}})$ equals $\sum (-1)^i [P^i]$. We prove this fact by induction on the (fine) length of $X$. The length one case follows immediately from Proposition 6.4.1 (and the conservativity of $t$ can be considered as a partial case of this statement).

To make the inductive step it suffices to show the existence of a morphism $l : P^j \to X$ in $DM_{gm}^{\text{eff}}$ that gives the obvious morphism of complexes after we apply $t$ to it. Indeed, then the length of the cone of $l$ would be less than $j - i$ (cf. part 4 of Proposition 2.6.1).

By Proposition 6.4.1, $X$ is a direct summand of some $X' \in H_{i,j}$. Hence the existence of $l$ follows from part 3 of Theorem 6.2.1.

Corollary 6.4.3. $t_{gm}$ (defined in part 3 of Remark 6.3.2) induces an isomorphism $K_0(DM_{gm}) \to K_0(\text{Chow})$.

Proof. Note that the definitions of the Tate twist on $\mathcal{H}$ and $\text{Chow}^{\text{eff}}$ is compatible. Since $-1$ is an autoequivalence on $DM_{gm} = \cup DM_{eff}^{gm}(-i)[-2i]$ and on $K^b(\text{Chow}) = \cup K^b(\text{Chow}^{\text{eff}})(-i)[-2i]$, we obtain the claim (from Theorem 6.4.2).

Remark 6.4.4. 1. Note that the categories $\text{Chow}^{\text{eff}} \subset DM_{gm}^{\text{eff}}$ have compatible tensor categories structures. Hence their $K_0$-groups are actually rings, whereas the isomorphism constructed is an isomorphism of rings.

The same is true for $\text{Chow} \subset DM_{gm}$.

2. Alternatively, one can prove Corollary 6.4.3 by noting that $K_0(\text{Chow}) = K_0(\text{Chow}^{\text{eff}})[\mathbb{Z}(1)]^{-1}$ and $K_0(DM_{gm}) = K_0(DM_{gm}^{\text{eff}})[\mathbb{Z}(1)]^{-1}$.

6.5 Explicit calculation of $m^{-1}(M^c_{gm}(X))$; the weight complex of smooth quasi-projective varieties

Let $M^c_{gm}(X)$ for $X \in \text{SmCor}$ denote the motif of $X$ with compact support (cf. §2.2 or §4.1 of [Voe00a]).

Proposition 6.5.1. For a smooth quasi-projective $X/k$ let $j : X \to P$ be an embedding for $P \in \text{SmPrVar}$, let $P \setminus X = \cup Y_i, 1 \leq i \leq m$, be a smooth normal crossing divisor. Let $U_i = \sqcup_{(i_j)} Y_i \cap Y_{i_2} \cap \cdots \cap Y_{i_r}$ for all $1 \leq i_1 < \cdots < i_r \leq m$, $U_0 = P$. We have $r$ natural maps $U_r \to U_{r-1}$. We denote by $d_r$ their alternated sum (as a finite correspondence). We consider $Q = (Q^i, f_{ij})$, where $Q^i = U_i$ for $0 \leq i \leq -m$, $P^i = 0$ for all other $i$; $f_{ij} = d_i$ for $0 > i \geq -m$, $j = i + 1$, and $f_{ij} = 0$ for all other $(i, j)$. Then $M^c_{gm}(X) \cong m(Q)$.
Proof. Let $j^*$ denote the natural morphism $M_{gm}^c(P) = M_{gm}(P) \to M_{gm}(X)$ (see 4.1 of [Voe00a]). Then by Proposition 4.1.5 loc. cit. the cone of $j^*$ is naturally isomorphic to $M_{gm}(R_0) = M_{gm}(R_0)$, where $R_0 = \cup Y_i$ (note that $R_0$ is proper). Hence our assertion is equivalent to the statement that $C(R) \cong 0$, where $C$ denotes the Suslin complex of $R$,

$$R = L(U_m) \xrightarrow{d_m} L(U_{m-1}) \xrightarrow{d_{m-1}} \cdots \xrightarrow{d_2} L(U_1) \to L(R_0).$$

Now, it remains to note that $R$ is acyclic as a complex of presheaves. The latter fact easily follows from the definition of $SmCor$, since obviously: for any $Z \in SmVar$ if $T \subset Z \times R_0$ is closed integral, then $T \subset Z \times Y_i$ for some $i$.

See also Lemma 7.1 of [Sus03].

We also get an explicit presentation of $M_{gm}^c(X)$ as a complex over $SmCor$ (this corresponds to the first description of $DM_{gm}^{eff}$ in [Voe00a]). The terms of the complex are (motives of) smooth projective varieties.

Remark 6.5.2. 1. Applying Proposition 6.5.1 along with the statements of subsection 7.3 below we get a nice machinery for computing cohomology with compact support. Moreover, Proposition 6.5.1 appears to be connected with the Deligne's definition of (mixed) Hodge cohomology of smooth quasi-projective $X$. This is no surprise (cf. subsection 7.4 below); yet a deeper understanding of this matter could improve our understanding of cohomology.

2. Using Proposition 6.5.1 along with Theorem 3.1.1 one can write an explicit formula for $DM_{gm}^{eff}(M_{gm}^c(X), M_{gm}^c(Y))$ for smooth quasi-projective $X, Y/k$.

Using section 4.3 of [Voe00a] one can also calculate $DM_{gm}^{eff}(M_{gm}(X), M_{gm}(Y)[s])$ for any $X, Y \in SmVar$, $s \in \mathbb{Z}$. Indeed, if $\dim X = m, \dim Y = n$, $X, Y$ are smooth equidimensional, then (in the category of geometric motives $DM_{gm}$)

$$DM_{gm}^{eff}(M_{gm}(X), M_{gm}(Y)[s]) = DM_{gm}(M_{gm}(Y)^*, M_{gm}(X)^*[s]) = DM_{gm}(M_{gm}(Y)(-n)[-2n], M_{gm}(X)(-m)[-2m + s]) = DM_{gm}^{eff}(M_{gm}^c(Y)(m)[2m], M_{gm}^c(X)(n)[2n + s]);$$

one can also use $\tilde{H}_{gm}$ for these calculations.

In the §2 of [GIS96] for any $X/k$ a certain weight complex $W(X)$ of Chow motives was defined. In order to make the notation of [GIS96] compatible with ours we reverse the arrows in the category of Chow motives. Thus we consider homological Chow motives instead of cohomological ones considered in [GIS96]. We have $W(X) \in K^-(Chow^{eff})$.

Let $m^{-1}$ denote the equivalence of $DM^s \subset DM_{gm}^{eff}$ with $\tilde{H}$ inverse to $m$. 45
Corollary 6.5.3. For any smooth quasi-projective $X/k$ we have $t_0(m^{-1}(M_{gm}^c(X))) \in K^b(Corr_{rat}) \cong W(X)$ (in $K^-(Chow^{eff})$).

Proof. By Proposition 2.8 of [GiS96] the weight complex of $X$ is isomorphic to the image in $K^b(Chow^{eff}) \subset K^-(Chow^{eff})$ of the complex $U$ defined in Proposition 6.5.1 (with arrows reversed).

6.6 cdh-hypercoverings; the weight complex of Gillet and Soulé for arbitrary varieties

We recall one of the main tools of [Voe00a] (cf. Definition 4.1.9); it allows computations with motives of non-smooth varieties.

Definition 6.6.1. cdh-topology is the smallest Grothendieck’s topology such that both Nisnevich coverings and coverings of the form $X' \coprod Z \to X$ are cdh-coverings; here $p: X' \to Z$ is a proper morphism, $i: Z \to X$ is a closed embedding, and the morphism $p^{-1}(X - i(Z)) \to X - i(Z)$ is an isomorphism.

By Lemma 12.26 of [MVW06], proper cdh-coverings are exactly envelopes in the sense of 1.4.1 of [GiS96]. Therefore, a hyperenvelope in the sense of [GiS96] is exactly the same thing as a proper cdh-hypercovering. We recall that a cdh-hypercovering is an augmented simplicial variety $X$, such that each $X_i \to (cosk_{k-1}sk_{k-1}(X))_i$ is a cdh-covering.

We introduce the category $Sch^{prop}$. Its objects are varieties over $k$, its morphisms are proper morphisms of varieties.

In [GiS96] the weight complex functor $W: Sch^{prop} \to K^b(Chow^{eff})$ was defined in the following way. The weight complex for a simplicial smooth projective variety $T$ was defined (up to the reversion of arrows) as $T_0 \to T_1 \to T_2 \to \ldots$; the boundary maps were given by alternated sums of face maps. Recall that we reverse arrows in $W(T)$!

For $X \in Var$ a proper $Y \supset X$ was chosen; $Z = Y - X$. It was shown in [GiS96] that there exist hyperenvelopes $Z$ of $Z, Y$, of $Y$, and a simplicial closed embedding $Z \to Y$, extending the map $Z \to Y$, whereas the terms of $Z$ and $Y$ are smooth projective varieties. Then $W(X)$ was defined as the cone of $W(Z.) \to W(Y.)$ (if we reverse arrows). By means of comparing different hyperenvelopes Gillet and Soulé showed that $W(X)$ is well-defined as an object of $K^b(Corr_{rat})$ and gives a functor $Sch^{prop} \to K^b(Corr_{rat})$.

Proposition 6.6.2. The functor $t_0(m^{-1}(M_{gm}^c(X))) : Sch^{prop} \to K^b(Corr_{rat})$ is equivalent (after we reverse all arrows) to the functor $W$.

Proof. We recall that to compare $t_0 \circ m^{-1} \circ M_{gm}^c$ with the functor of Gillet and Soulé we should fix some choice of $m^{-1} \circ M_{gm}^c$ (a priori the latter one is only
defined up to an isomorphism, cf. Remark 3.1.2. So first we should check that \( t_0(m^{-1}(M_{gm}^c(X))) \) is isomorphic to the weight complex of \( X \) defined in [GiS96]; this doesn’t require any choices.

Since \( Y. \to Y \) is a cdh-hypercovering, the cdh-sheafification of the corresponding complex \( L(Y.) \to L(Y) \) is quasi-isomorphic to 0. Then Theorem 5.5 of [FrV00] shows that \( C(Y.) \cong C(Y) \). Hence \( C(Y.) \) calculates \( M_{gm}(Y) \). The same is true for \( Z \).

By Proposition 4.1.5 of [Voe00a] there exists a distinguished triangle

\[
M_{gm}(Z)(= M_{gm}^c(Z)) \to M_{gm}(Y)(= M_{gm}^c(Y)) \to M_{gm}(X) \to M_{gm}(Z)[1]
\]

in \( DM_{gm}^{eff} \). Hence we obtain that \( t_0(m^{-1}(M_{gm}^c(X))) \cong W(X) \) (in \( K^-(Chow^{eff}) \)).

The definitions imply that \( W \) and \( t_0(m^{-1}(M_{gm}^c(X))) \) coincide as functors on the category of proper smooth varieties (cf. Remark 3.1.2). In order to compare the functors in general we can define \( m^{-1} \circ M_{gm}^c \) using the method of §2 [GiS96] (see the description above). It can be easily seen that this method allows lifting \( W(X) \) to a functor \( W': Sch_{prop} \to H \) which (as we have just proved) can be identified with \( m^{-1} \circ M_{gm}^c \). Certainly, in order to prove that \( W' \) is well-defined one should replace the usage of the Gersten acyclicity (i.e., of Proposition 2 of 1.4.3 of [GiS96]) in the proof of Theorem 2 of [GiS96] by the usage of Theorem 5.5 of [FrV00].

\[ \square \]

Remark 6.6.3. 1. In Theorem 5.10 of [GN-A02] also a certain functor \( h: Sch_k \to K^b(Chow^{eff}) \) was constructed (\( Sch_k \) is the category of varieties over \( k \)). It can be shown that \( h \) is equivalent to the restriction of \( t: DM_{gm}^{eff} \to K^b(Chow^{eff}) \) to motives of varieties (see subsection 6.4 for the definition of \( t \)).

2. In §2 of [GiS96] it was shown that any two different representatives \( W_i \) of \( W(X) \) (considered as complexes over \( SmCor \)) can be connected by a chain of certain homomorphisms \( h_i \) of complexes of smooth projective varieties. Gillet and Soulé proved that \( h_i \) induce isomorphisms on the level of \( K^b(Corr_{rat}) \). The main technical tools were Proposition 2 and Theorem 1 of §1 of [GiS96] showing that hyperenvelopes give quasi-isomorphisms of complexes of Chow motives.

To any such \( W_i \) we can associate an object of \( \mathcal{H} \). Since \( t_0(h_i) \) is an isomorphism, the corresponding map of motives will be an isomorphism too, see part 6 of Theorem 6.2.1.

Hence one can prove that the method of [GiS96] gives a well-defined motif without using the cdh-descent reasoning above.
3. More generally, one can easily define Voevodsky’s motives of Deligne-Mumford stacks (i.e., for stacks coming from quotients of varieties by finite groups) over $k$. For a finite $G$, $\#G = n$, acting on a variety $X/k$ one can take $M_{gm}(X/G)_\mathbb{Q} = a_G M_{gm}(X_\mathbb{Q}) \in DM_{gm}^{eff} \mathbb{Q}$ and $M_{gm}^c(X/G)_\mathbb{Q} = a_G M_{gm}^c(X_\mathbb{Q}) \in ObjDM_{gm}^{eff} \mathbb{Q}$. Here $a_G$ is the idempotent correspondence $\sum_{g \in G} g^n : X \to X$. As we have noted above there exists a conservative exact weight complex functor $t_\mathbb{Q} : DM_{gm}^{eff} \mathbb{Q} \to Chow^{eff} \mathbb{Q}$ (with properties similar to those of $t$). Certainly, for $G = \{e\}$ we will have $t_\mathbb{Q}(M_{gm}(X/G)) = t(M_{gm}(X))$ and $t_\mathbb{Q}(M_{gm}^c(X/G)) = t(M_{gm}^c(X))$. Besides, it is most probable that $t_\mathbb{Q}(M_{gm}^c(X/G))$ would coincide with the weight complex for $X/G$ defined by H. Gillet and C. Soulé (see Proposition 14 of [GiS07]). Indeed, both of these weight complexes can be calculated using proper hypercoverings of $X/G$. So it seems that the method of the proof of Proposition 6.6.2 could be extended to this case. Still the details of the proof of the isomorphism (as well as of [GiS07]) have to be written out.

7 Realizations of motives; weight filtration; the spectral sequence of motivic descent

One of the main parts of the theory of motives is the problem of constructing and studying different realizations, i.e., exact functors $DM^* \to T$ for $T$ being a triangulated category. Some authors consider functors from the category of (smooth) varieties to $T$, yet usually those functors can be factored through $DM^*$ (cf. [Hub00] and [Lev98]).

In subsection 7.1 we recall that any differential graded functor from $J$ gives a realization of $\mathcal{H}$ (and $DM^*$). This method of constructing realizations is a vast generalization of the method described in 3.1.1 of [GiS96]. We call realizations that can be constructed from differential graded functors enhanceable realizations; this class seems to contain all ’standard’ realizations as well as all representable functors for the category of motives (cf. subsections 7.2 and part 1 of Remark 7.3.1). In particular, in 7.2 we verify that the étale cohomology realization is enhanceable; a reader who believes in this fact could skip this subsection.

For any enhanced realization $D$ in 7.3 we define a family of truncated realizations. One could say that truncated realizations correspond to ’forgetting cohomology outside a given range of weights’. In particular, for ’standard’ realizations and motivic cohomology one obtains an interesting new family of realizations this way.

In subsection 7.3 we also prove that truncated realizations of length $N$...
can be factored through \( t_N \); they give a filtration on the natural complex that computes \( D \). We obtain a spectral sequence \( S \) converging to \( D(Y) \) for a motif \( Y \). \( S \) could be called the \textit{spectral sequence of motivic descent} (note that the usual cohomological descent spectral sequences compute cohomology of varieties only). For the cohomology with compact support of a variety \( S \) is very similar to the spectral sequence considered in 3.1.2 of [GiS96]; yet the origin of \( S \) is substantially different from those of the mentioned one. Besides we don’t need the sheaves to be torsion as one does for étale cohomology. \( E_n(S) \) can be expressed in terms of \( t_{2n-2}(Y) \) (see (15)); in particular, \( E_1 \)-terms depend only on \( t_0(Y) \) and have a nice description in terms of cohomology of smooth projective varieties. \( S \) gives a canonical weight filtration on a wide class of cohomological functors; for the ’standard’ realizations this filtration coincides with the usual one (with indices shifted).

We note that (as an easy partial case of our results) we get a canonical ’weight’ filtration on the motivic cohomology of any variety and the corresponding ’weight’ spectral sequence for it. \( S \) (and the filtration) are ’motivically functorial’; they are also functorial with respect to ’enhanced’ transformations of functors (this includes regulator maps).

In subsection 7.4 we verify that the our definition of weights gives classical weights for ’standard’ realizations (at least, rationally). Moreover, if \( W \) denotes the weight filtration on \( H^i(X) \) then \( W_{l+N}H^i(X)/W_{l-1}H^i(X) \) is exactly the corresponding truncated realization; hence it factors through \( t_N \). A morphism \( f \) induces a zero morphism on cohomology if \( t_0(f) \) is zero. We also prove that the rational length of \( X \in DM_{\text{eff}}^{\text{gm}} \) coincides with the ’range’ of difference of \( l \) with the weights of \( H^i(X) \) for all \( l \) (cf. Proposition 7.4.2). If we assume certain ’standard’ conjectures then there would be an equality, see Proposition 7.4.2.

We conclude the section by the discussion of \( qfh \)-descent cohomology theories and \( qfh \)-motives of (possibly) singular varieties. It turns out that a wide class of realizations (including ’standard’ ones) are ’\( qfh \)-representable’ (hence they are enhanceable realizations of \( DM^s \)). Moreover, the \( qfh \)-motif of a (not necessarily smooth) variety gives ’right values of standard realizations’.

### 7.1 Realizations coming from differential graded functors (’enhanceable’ realizations)

We consider the problem of constructing and studying different \textit{realizations} of motives, i.e., exact functors \( DM^s \to T \) for \( T \) being a triangulated category. Our description of \( DM^s \) gives us a simple recipe for constructing realizations.
Any differential graded functor $F : J \to X$ for a differential graded category $X$ gives an exact functor $Tr^+(F) : \mathcal{H} \to Tr^+(X)$ (and hence also a functor $\mathcal{H} \to Tr(X)$), cf. Remark 2.3.3. It can be easily seen that $Tr^+(F)$ can be factored through $t_N$ if $t(J^l([Y], [Z])) = 0$ for any $Y, Z \in SmPrVar$, $l < -N$. This is always true if $X^l = 0$ for $l < -N$. One can also note that all functors factoring through $t_N$ can be reduced (in a certain sense) to functors of such sort.

We will say that $F$ gives an enhancement of the realization $Tr^+(F)$; a realization that possesses an enhancement can be called enhanceable. Obviously, any differential graded transformation of enhancement induces an exact transformation of realizations. We will mostly consider contravariant functors $F$.

Note that for $N = 0$, $X$ being equal to $S(A)$ for $A$ an abelian category (see the definition of $S(A)$ in [2.1], our construction of $Tr^+(F)$ essentially generalizes to motives the recipe proposed in 3.1.1 of [GIS96] for cohomology of varieties with compact support (also cf. [GN-A02]).

Note lastly that any exact functor $DM^s \to T$ can be uniquely extended to an exact functor from $DM^s_{gm}$ to the idempotent completion of $T$.

7.2 ‘Representable’ contravariant realizations; étale cohomology

Now we verify that a large class of realizations are enhanceable; this includes étale cohomology.

To this end we describe a recipe for constructing a rich family of contravariant differential graded functors from $J$. Let $A$ be a Grothendieck topology stronger than Nisnevich topology (for example, étale topology). We consider the category $Shv(SmCor)_A$ (i.e., the morphisms are those of $SmCor$, coverings are those of $A$); let $C(Shv(SmCor)_A)$ denote the category of (unbounded) complexes over $Shv(SmCor)_A$. We suppose that for any $X \in SmCor$ the representable presheaf $L(X) = SmCor(-, X)$ is a sheaf. We denote by $D(Shv(SmCor)_A)$ and $DM^s_{eff}$ the categories of unbounded complexes over $Shv(SmCor)_A$ that are similar to the corresponding categories of $[Voe00a]$ (i.e., derived category of complexes of sheaves, resp. derived category of complexes of sheaves with homotopy invariant cohomology). We also consider the categories $K(Shv(SmCor)_A)$ and $B(Shv(SmCor)_A)$ that are unbounded analogues of $K^-(Shv(SmCor)_A)$ and $B^-(Shv(SmCor)_A)$ (cf. [2.1]) respectively.

Now we verify that the étale cohomology realization is enhanceable in the case when $K$ has finite étale cohomological dimension. Let $Y \in C^+(Shv(SmCor)_A)$
be a complex of injective sheaves with transfers bounded from below with homotopy invariant hypercohomology (we need the hypercohomology condition if $A \neq Nis$). Now we consider $C(L(X))$ for $X \in SmVar$. Since $C(L(X))$ is quasi-isomorphic to $\underline{C}(L(X))$, for any $i \in \mathbb{Z}$ we have

$$D(Shv(SmCor)_A)(C(L(X)), Y[i]) = D(Shv(SmCor)_A)(\underline{C}(L(X)), Y[i]).$$

Since the correspondence $(F) \to \underline{C}(F)$ defines a functor $RC_A$ which is left adjoint to the embedding $DM_A^{eff} \to D(Shv(SmCor)_A)$ (cf. Proposition 3.2.3 of \cite{Voe00a}), $Y \in D(Shv(SmCor)_A)$, we have

$$D(Shv(SmCor)_A)(C(L(X)), Y[i]) = D(Shv(SmCor)_A)(L(X), Y[i]).$$

Let $Z \in Obj\mathcal{R} = ObjJ'$ satisfy $m(Z) \cong M_{gm}(X) = C(L(X))$ (in $D^-(Shv(SmCor))$) and so also in $D(Shv(SmCor)_A)$, cf. Corollary 3.2.1. Since the terms of $Y$ are injective sheaves, we conclude that

$$H^{-i}(Y)(X) = K(Shv(SmCor)_A)(L(X), Y[i]) \cong K(Shv(SmCor)_A)(h(Z), Y).$$

Moreover, the complex $B(Shv(SmCor)_A)(h'(Z'), Y)$ computes the complex $Y(X)$ up to a quasi-isomorphism (see the definitions of \cite{Voe00a}).

Now we describe how the formalism of §2 can be applied to the computation of $B(Shv(SmCor)_A)(h'(Z), Y)$. We have a contravariant functor $Y^* : J \to C(\mathbb{A})$ that maps $[P] \in ObjJ$ to $B(Shv(SmCor)_A)(C(P), Y)$. Let $a : J' \to Pre-Tr J \to B(Shv(SmCor)_A)$ denote the differential graded functor induced by the embedding $J \to B^{-}(Shv(SmCor)_A)$, cf. Remark 2.3.3 and Proposition 2.2.3. Since $Y^* = B(Shv(SmCor)_A)(-, Y) \circ a$, we obtain that

$$B(Shv(SmCor)_A)(h'(Z), Y) \cong Pre-Tr(Y^*)(Z).$$

Here $Pre-Tr(Y^*)$ denotes the extension of $Y^*$ to $J'$, cf. Remark 2.3.3.

For example, we can take $A$ being the étale site. One can take $Y$ being an injective resolution of $\mathbb{Z}/n\mathbb{Z}$ (or a resolution of any other étale complex $C$ with transfers with homotopy invariant hypercohomology) by means of étale sheaves with transfers. By Proposition 3.1.8 and Remark 2 preceding Theorem 3.1.4 in \cite{Voe00a} the cohomology of $Y(L(X))$ for $X \in SmVar$ will compute the 'usual' étale hypercohomology (i.e., in the category of sheaves without transfers) of $C$ restricted to $X$. Hence $Tr(Y^*)$ gives the corresponding realization of motives. We obtain that in order to compute the étale realization of motives (with coefficients in $\mathbb{Z}/n\mathbb{Z}(r)$ for any $n > 0$, $r \geq 0$) it suffices to know the restriction of the corresponding 'representable functor' to the subcategory of $Shv(SmCor)_A$ consisting of sheaves of the form...
For $P \in \text{SmPrVar}$. Note also that we can compute morphisms in the category of presheaves with transfers.

If $C$ is a complex of $cdh$-sheaves (see subsection 6.6) with transfers then the cohomology of $Y(L(X))$ for $X \in \text{SmVar}$ will compute the $cdh$-hypercohomology of $C$ restricted to $X$ for any $X/k$. Yet $cdh$-topology is not subcanonical; $cdh$-hypercohomology does not necessarily coincides with ‘usual’ hypercohomology of $C$. For the computation of ‘usual’ cohomology for singular varieties the $qfh$-topology seems to be more useful; see subsection 7.5 below.

One can check that the Galois action on $H^i_{et}(X \times_{\text{Spec } k} \text{Spec } \overline{k}, \mathbb{Z}/n\mathbb{Z})$, where $\overline{k}$ is the algebraic closure of $k$, $n$ is prime to the characteristic of $k$, can be expressed in terms of our formalism. Indeed, isomorphisms in the derived category corresponding to the Galois action can be extended to an injective resolution of $\mathbb{Z}/n\mathbb{Z}$. Therefore all statements of this section are valid for étale realization with values in Galois modules.

A similar method for constructing the étale realization (without using the formalism of differential graded categories) was described in [Hub00] (see the reasoning following Proposition 2.1.2). In the next subsection we describe a general method of obtaining weight filtrations for realizations.

It seems that that the same method can be applied to other ‘classical’ realizations including the ‘mixed realization’ one. Yet filling out the details is rather hard. Fortunately, one can avoid this by applying the weight structure formalism of [Bon10]; see Remark 7.4.4 below.

### 7.3 The spectral sequence of motivic descent; weight filtration of realizations; the connection with $t_N$

Now we consider a contravariant functor $F : J \to B(A)$ for an abelian $A$. We denote the functor $\text{Pre-Tr}(F) : J' \to B(A)$ by $G$, denote $\text{Tr}(F) : \mathcal{F} \to K(A)$ by $E$.

It seems very probable that one can ‘enhance’ all ‘classical’ realizations this way (possibly, for a ‘large’ $A$). Besides, it practice it usually suffices to consider functors whose targets are categories of complexes bounded (at least) from one side.

The constructions of this subsection use the results of subsection 2.7 heavily.

We recall that for a complex $X$ over $A$, $a,b \in \mathbb{Z}$, $a \leq b$, its canonical $[a,b]$-truncation is the complex

$$X^a/dX^{a-1} \to X^{a+1} \to \ldots X^{b-1} \to \text{Ker}(X^b \to X^{b+1}),$$
here $\ker(X^b \to X^{b+1})$ is put in degree $b$; for $a = b$ we take $H^a(X)$. We also consider truncations of the type $\tau_{\leq b}$ (i.e., truncations from above).

For any $b \geq a \in \mathbb{Z}$ we consider the following functors (see subsection 2.7). By $F_{\tau_{\leq b}}$ we denote the functor that that sends $[P]$ to $\tau_{\leq b}(F([P]))$. By $F_{\tau_{[a,b]}}$ we denote the functor that that sends $[P]$ to $\tau_{\leq b}(F([P]))/\tau_{\leq a-1}(F([P]))$.

For $N = a - b$ we consider the functor $F_{b,N}$ that sends $[P]$ to the $[a,b]$-th canonical truncation of $F([P])$. These functors are differential graded; hence they extend to $G_b = \text{Pre-Tr}(F_{\tau_{\leq b}}) : J' \to B^-(A)$, $G_{b,N} = \text{Pre-Tr}(F_{b,N}) : J' \to B^b(A)$, and $G_{a,b} = \text{Pre-Tr}(F_{\tau_{[a,b]}}) : J' \to B^b(A)$. We recall that $G_{a,b}$ and $G_N$ are connected by a canonical functorial quasi-isomorphism, see part 2 of Proposition 2.7.3. The reason for considering both of them is that the functors $G_{a,b}$ are more closely related to the spectral sequence (14) below, whereas $G_N$ behave better with respect to $t_N$.

We denote $\text{Tr}(F_{b,N}) : \mathcal{H} \to K^b(A)$ by $F^b_N$. Since $F_{b,N}$ is concentrated in degrees $[b - N, b]$, $F_{b,N}$ maps all $J^m(X,Y)$ for $X,Y \in \text{Obj} J$, $m < -N$, to 0. Hence one can present $F^b_N$ as $b_{N,N} : \mathcal{H} \to K(A)$ for a unique $b_{N,N} : \mathcal{H} \to K(A)$. The set of $F^b_N$ could be called truncated realizations for the realization $E; N$ is the length of the realization. These realizations appear to be new even in the case when $E$ is the étale cohomology. Note that for $X = [P]$, $P \in \text{SmVar}$, the truncated realizations give exactly the corresponding truncations of $E([P])$ (i.e., of the corresponding ‘cohomology’ of $P$); that is what one usually expects from the weight filtration.

The complexes $G_b(X)$ give a filtration of $G(X)$ for any $X \in \text{Obj} J'$; moreover $G_{a,b}(X) = G_b(X)/G_{a-1}(X)$.

Let $X = (P^i, q_{ij}) \in \text{Obj} J' = \text{Obj} \mathcal{H}$. We obtain the spectral sequence of a filtered complex (see §III.7.5 of [GeM02])

$$S : E_{ij}^j(S) \Rightarrow H_{i+j}(G(X))$$

we call it the spectral sequence of motivic descent. Here $E_{ij}^j(S) = H_{i+j}G^{b,j}(X) = H_{i+j}(F^j_b(X))$. Note that $H_{i+j}(G(X)) = H_{i+j}(E(X))$, in the right hand side we consider $X$ as an object of $\mathcal{H}$. It is easily seen that $S$ is $\mathcal{H}$-contravariantly functorial in $X$; in fact, they are also functorial (for example, see (15)) below. In fact, one could also define $E_0(S)$; this would be $\mathcal{H}$-functorial also, yet difficult to compute.

Moreover, if $h : F \to F'$ is a differential graded transformation of functors then the corresponding map of spectral sequences depends only on $Tr(h)$. In particular, for the étale realization the spectral sequence does not depend on the choice of an injective resolution for the corresponding complex (see the previous subsection).

The spectral sequence $S$ is similar to those coming from hypercoverings.
(and hyperenvelopes). Yet its terms are 'much more functorial'; it computes cohomology of any motif (not necessarily of a motif of a variety).

By definition, $E^i_j(S) = H^{i+j}(F^i_0(Y))$ is the $i$-th cohomology group of the chain complex $A_l = H^i(P^{-l})$. Hence the $E_l$-terms are functorial in the complex $(P^l) \in K^b(Corr_{rat})$, i.e., in $t_0(Y)$. $S$ is convergent: if for $X$ of (stupid) length $N$ we choose a representative in $S'$ of length $N$ then only $N + 1$ rows of $E_l(S)$ would be non-zero. Besides if all $F^0_i(Y)$ are acyclic then $E(Y)$ is acyclic. We denote the filtration on $H^s(E(Y))$ given by $S$ by $W_l$; we call it the weight filtration of $H^s$.

For any $b, N$ we also have a 'spectral subsequence'

$$S^b_N : E^i_j(S^b_N) \implies H^{i+j}(G_{a,b}(X)) = H^{i+j}(G^b_N(X)) = H^{i+j}(F^b_N(Y)).$$

Its $E_l$-terms form a subset of the $E_l$-terms of $S$, the (non-zero) boundary maps are the same. We also have weight filtration on $H^s(F^b_N(Y))$.

For any $0 \leq l \leq N$ we have an obvious spectral sequence morphism $E^b_{N-1} \to S^b_N$. It induces an epimorphism

$$\alpha^s_{l,b,N} : H^s(F^b_{N-l}(Y)) \to W_{b-l}(H^s(F^b_N(Y))).$$

Now we use an argument that can be applied to any filtered complex. For any $N \geq 0, n \geq 1$, one easily sees that $E^0_i(S^b_N) = E^0_i(S^b)$ if $b - n < j < b - N + n$. Moreover, if $b + 1 - n \geq j \geq b - N + n - 1$ then $E^i_j(S^b_N) = E^i_j(S)$. Therefore we have

$$E^i_j(S) = G^W_{n-1} H^{i+j}(F^{i+n-1}_{2n-2}(Y)) = W_{n-1}(H^{i+j}(F^{i+n-1}_{2n-2}(Y)))/W_{n-2}(H^{i+j}(F^{i+n-1}_{2n-2}(Y)))$$

\[= \text{Im} \alpha^i_{n-1,j+n-1,2n-2}/\text{Im} \alpha^i_{n,j+n-1,2n-2}, \tag{15}\]

i.e., it is the middle factor of the weight filtration of $H^{i+j}(F^{i+n-1}_{2n-2}(Y))$. A similar equality can be written for $E^b_i(S^b_N)$ for any $b \in \mathbb{Z}, N \geq 0, n \geq 1$. Hence for any $n \geq 1$ the $E_n$-terms of $S$ and all $S^b_N$ depend only on $t_{2n-2}(Y)$.

Suppose that $X \in S'[c,d]$. It can be easily verified (for example, using the spectral sequence (14)) that for any $j \in \mathbb{Z}, b - N - c \leq j \leq b - d$, the $j$-th cohomology group of $F^b_N(Y)$ coincides with $H^j(E(Y))$. Besides for any $j \in \mathbb{Z}$ the weights of $H^j(E(Y))$ lie between $j + c$ and $j + d$. In particular, by part 1 Theorem 6.2.4 the weights of $H^j(X)$ for $X \in SmVar$ of dimension $N$ lie between $j$ and $j + N$, the weights of $H^j_c(X)$ (the cohomology with compact support) lie between $j - N$ and $j$.

Hence all 'cohomological information' of a motif of length $\leq N$ can be factored through $t_N$ (in order to prove this for fine length $\leq N$ one should use Proposition 6.4.1). This statement can be considered as the 'realization version' of Theorem 6.2.4 (parts 1 and 2).
Remark 7.3.1. 1. For an object $U \in Obj J' = Obj \mathcal{F}' = Obj H'$ (recall that $J' = \text{Pre-Tr}(J)$) one can consider the differential (contravariant) graded functor $J_U : J \to B(Ab)$ that maps $[P]$ to $J'([P], U)$. Then $H^n(Tr(U))(X) = \mathcal{F}(X, U[i])$; this means that representable realizations are enhanceable.

In particular, we can take $U = \mathbb{Z}(n)$ for $n \geq 0$. Hence we obtain canonical 'weight' filtration on the motivic cohomology of any variety and the corresponding 'weight' spectral sequence for it. A simple example of this spectral sequence is closely related with the Bloch’s long exact localization sequence (see [Blo94]).

Indeed, let $Z \subset X \in SmPrVar$, $Z$ is everywhere of codimension $c$, let $Y = X - Z$. Then (cf. the proof of part 1 of Theorem 6.2.1) the motif of $Y$ is a cone of $M_{gm}(X) \to M_{gm}(Z)(c)[2c]$. So the length of $M_{gm}(Y)$ is 1; hence for any realization the formula for $E_1(S)$ relates the cohomology of $Y$ with those of $X$ and of $Z(c)[2c]$. If the realization is motivic cohomology then this relation is exactly the same as given by the exact sequence of Bloch. See also the end of Remark 2.4.2 of [Bon10] and Remark 7.4.4 below.

This example shows that the weight filtration obtained this way is non-trivial in general; it appears not to be mentioned in the literature. The filtration is compatible with the regulator maps (whose targets are 'classical' cohomology theories).

Using the spectral sequence relating algebraic $K$-theory to the motivic cohomology (see [FrS02] and [Sus03]), one can also obtain a new filtration on the $K$-theory of a smooth variety $X$.

2. The spectral sequence functor described is additive (here we fix $F$ and consider $S$ as a functor from $\mathcal{F}$). Hence one can easily see that this functor can be uniquely extended to the whole $DM_{gm}^{eff}$.

3. It seems to be interesting to study the truncations and the weight spectral sequence for the cohomology of the sheaf $Y \to G_m(X \times Y)$ for a fixed variety $Y$ ($G_m$ is the multiplicative group). These things seem to be related with the Deligne’s one-motives of varieties as they were described in [B-VRS03].

More generally, for any $X \in DM_{gm}^{eff}$ the functor $\text{Hom}(-, X) : DM_{gm}^{eff} \to DM_{gm}^{eff}$ is enhanceable.

4. In Remark 6.4.1 of [Bon10] we verify that the truncated realizations coming from representable realizations are representable also. The truncated realizations are represented by $t$-truncations of the objects representing the original realizations with respect to a certain Chow $t$-structure. Note that this is the case for motivic cohomology and for ‘classical’ realizations of motives (with values in $Ab$).

More generally, one can define a $t$-structure on the category $Tr(DG -$
Fun(J,B(A))) (differential graded functors) that corresponds to the canonical truncation of A-complexes. Then the realizations of the type considered here correspond to some objects of this category; truncations of a realization with respect to this t-structure would be exactly its truncated realizations.

5. Another important source of differential graded functors from J (generalizing representable functors considered in part 1) are those coming from localizations of \( A \) (or of \( DM^* \) which is the same thing). It will be discussed in subsection 8.2 below.

7.4 Comparison with ’classical weights’; comparison of the rational length with the ’Hodge length’

Suppose now that there are no maps between different weights, i.e., for any \( P, P', Q, Q' \in SmPrVar, f \in SmCor(P,P'), g \in SmCor(Q,Q'), i \neq j \), we have

\[
A(\text{Ker}(H^i(E([P']))) \xrightarrow{f^*} H^i(E([P]))) , (\text{Coker}(H^j(E([Q']))) \xrightarrow{g^*} H^j(E([Q]))) = 0.
\]

Recall that this condition is fulfilled for the étale and Hodge realizations with rational coefficients. Then \( S \) and all \( S^b_N \) degenerate at \( E_1 \). Therefore \( H^lF^b_N(X) = W_b(H^l(E(Y)))/W_{b-N-1}(H^l(E(Y))) \).

Besides, if there are no maps between different weights (in some variation of the target category), then for any \( H^l(X) \) there cannot exist more than one filtration \( W_j \) on \( H^l(X) \) such that \( W_j/W_{j-1} \) is of weight \( j \). Hence for the étale and Hodge realizations our weight filtration coincides with the usual one (with indices shifted). Therefore, \( t_N \) can be called the weight functors.

The existence of the weight spectral sequence easily implies that the length of the weight filtration of \( H^l \) is not larger than the stupid length of \( M \in ObjDM^* \). Moreover, Proposition 6.4.1 gives the same inequality for the fine length of any object of \( DM^\text{eff}_{gm} \) and also for the rational length (on the rational level). Besides, if \( M \in DM^\text{eff}_{gm}^{[a,b]} \), then the weights of \( H^l \otimes \mathbb{Q}(M) \) lie between \( l + a \) and \( l + b \).

Conjecture 7.4.1. The converse implication is true also, i.e., if for all \( l \) the weights of \( H^l \otimes \mathbb{Q}(M) \) (here \( H^* \) is the singular cohomology) lie between \( l + a \) and \( l + b \) then \( M \in DM^\text{eff}_{gm}^{[a,b],\mathbb{Q}} \).

Now we show that Conjecture 7.4.1 follows from certain ’standard’ conjectures.

Proposition 7.4.2. Suppose that following statements are valid:

1. The Hodge conjecture.
2. Any morphism of Chow motives that induces an isomorphism on singular cohomology is an isomorphism.

Then Conjecture 7.4.1 is also valid.

Proof. Indeed, we should check that if $M \not\in DM_{gm}^{eff} [a, b] \otimes \mathbb{Q}$ then at least for one $l$ the weights of $H^l \otimes \mathbb{Q}(M)$ do not lie between $l + a$ and $l + b$. Using Proposition 6.4.1 we obtain that we have the motivic descent spectral sequence for the singular realization of objects of $DM_{gm}^{eff}$; its $E_1^{ij}$-term is the $i$-th cohomology group of the chain complex $A_l = H^l(P^{-1})$. Therefore one should check

(1) If the 'first term' of $t_\mathbb{Q}(M) = (P^i)$ is at $c$-th place and the map $g : P^c \to P^{c+1}$ is not a projection onto a direct summand then for some $l$ the $(l + c)$-th weight component of $H^l \otimes \mathbb{Q}(M)$ is non-zero.

(2) The dual statement.

We verify (1); (2) is similar (and follows from (1) by duality). Suppose that for any $l$ the $l + c$-th weight piece of $H^l \otimes \mathbb{Q}(M)$ is zero. Note that this piece equals $\text{Coker}(g_l^* : H^l(P^{c+1})) \to H^l(P^c)$; hence all $g_l^*$ are surjective. Since the category of (rational) polarizable pure Hodge structures is semisimple, we can choose a family of splittings for $g_l^*$ (that respect the Hodge structures). Since the splittings are Hodge, by Hodge conjecture (for $(P^c \times P^{c+1})$ we obtain that these splittings can be realized by a morphism $h : P^{c+1} \to P^c$ of Chow motives. We obtain that $H^* (h)$ gives a splitting of $H^*(g)$; the assumption (2) (applied to $h \circ g$) implies that $g$ is a projection onto a direct summand. \hfill \Box

Remark 7.4.3. 1. Note that Conjecture 7.4.1 implies the conservativity of the singular realization, which certainly implies condition 2 of Proposition 7.4.2.

2. In order to get a similar result for the étale realization one should replace the Hodge conjecture by the Tate conjecture.

3. One could also count the (minimal) number of non-zero terms of $t(M)$.

We also note that for any morphism $f : Y \to Z$ for $Y, Z \in \mathfrak{H}$ the morphisms $H^i(f) : H^i(E(Y)) \to H^i(E(Z))$ for $Y, Z \in \mathfrak{H}$ are strictly compatible with the weight filtration. Therefore $H^i(f)$ is zero if and only if the corresponding map of $E_1$-terms in $S(Y) \to S(Z)$ is zero. Hence the map $\mathfrak{H}(Y, Z) \to A(H^i(E(X)), H^i(E(Y)))$ factors through $t_0$.

For cohomology with integral coefficients one may apply the previous statement for rational cohomology to obtain that $f^*$ is zero on $H^i \otimes \mathbb{Q}$ if $t_0(f) = 0$. Hence if $t_0(f) = 0$ then $f^*$ is zero on cohomology modulo torsion.

Using the results of subsection 6.6 one can compute $\mathfrak{H}(Z, T)$ for $Z = m^{-1}(M_{gm}(X))$, $T = m^{-1}(M_{gm}(Y))$, and also compute

$$M_N(X, Y) = \text{Im} \ t_N(\mathfrak{H}(Z, T) \to \mathfrak{H}(t_N(Z), t_N(T))).$$

57
Remark 7.4.4. Formally all our filtrations and spectral sequences depend on the choices of enhancements for realizations. One can check that they are independent in fact; yet in order to use the theory described above it is necessary (at least) to prove that enhancements exist. This seems to be true for all reasonable cases; yet proofs could be difficult (see 7.5 below).

There is a way to avoid these difficulties completely; it is studied in [Bon10]. The idea is to consider a set of axioms of so-called weight structures for a triangulated category $C$; the axioms are somewhat similar to those for $t$-structures (yet the consequences of the axioms are quite distinct!). One could say that any object of $C$ has a weight decomposition which is not unique but is 'unique up to a homotopy' (in a certain sense). In the case when $C = \mathcal{S}$ one could consider the decompositions given by the 'stupid filtration' (see Proposition 2.6.1). Then for any (covariant) functor $H : C \to A$, where $A$ is an abelian category, one can consider the filtration of $H(X)$ by $H(X_{[a, +\infty)})$ for $a \in \mathbb{Z}$. Note that while $X$ does not determine $X_{[a, +\infty)}$ uniquely, it does determine the image of $H(X_{[a, +\infty)})$ in $H(X)$. If $H$ is contravariant then one should consider the image $H(X_{[-\infty, b]}) \to H(X)$. The objects $X_{[a, +\infty)}$, $X_{[-\infty, b]}$ give a Postnikov tower for $X$; this yields a spectral sequence $T$ converging to $H(X)$. Its $E_1$-terms are $H_*(P^i)$; hence they are not determined by $X$. Yet starting from $E_2$ all terms of the spectral sequence are canonical and functorial in $X$. In fact, the filtration induced by $G_i$ on $G$ can be obtained from the filtration for $T$ by Deligne's decalage. Hence the spectral sequences and the filtration for $T$ coincide (up a certain shift of indices) with the terms of $S$ defined in (14).

This approach for constructing weight filtrations of realizations of Hanamura’s motives was described in [Han99]; yet the proof of Proposition 3.5 loc. cit. relies heavily on (sort of) enhancements for realizations.

The advantage of our alternative approach is that enhancements are no longer needed; in particular, it can be applied to the stable homotopy category for which no (differential graded) enhancements exist. Yet in this abstract setting it is difficult to define truncation functors (especially the 'higher' ones). The reason for that is (as was noted by several authors) that the axiomatics of an (abstract) triangulated category is not 'rigid enough'.

### 7.5 $qfh$-descent cohomology theories; motives of singular varieties

Some 'standard' cohomology theories are difficult to represent by a complex of sheaves with transfers (in the way described in subsection 7.2). One of the ways to do this is to use $qfh$-topology.
We recall that the $qfh$-topology is the topology on the set of all varieties whose coverings are quasi-finite universal topological coverings (see [Voe96] for a precise definition). In particular, the $qfh$-topology is stronger than the flat topology and the $cdh$-topology. There is a natural functor from $DM_{qfh}^{eff}$ to the derived category of $qfh$-sheaves with homotopy invariant cohomology (it is denoted as $DM_{qfh}(k)$); this functor is surjective on objects. Note also that any 'ordinary' topological sheaf restricted to $Var$ gives a $qfh$-sheaf. Moreover, $qfh$-descent follows from proper descent combined with Zariski descent (see section 2 of [Voe96]).

Let $C$ be a complex of presheaves (possibly without transfers) whose hypercohomology satisfies $qfh$-descent. Then the $qfh$-hypercohomology of the $qfh$-sheafification of $C$ coincides with the hypercohomology of $C$ (for example, a similar statement was proved in the proof of Theorem 5.5 of [FrV00]). Therefore if the cohomology of $C$ is homotopy invariant then it can be presented by means of 'representable' functors on $DM^*$ as it was described in subsection 7.2 above. In particular, this shows that Betti and Hodge cohomology theories can be enhanced to differential graded realizations.

Now let $C$ be a complex of $qfh$-sheaves. It was proved in [Voe96] (see Theorems 3.4.1 and 3.4.4) that the $qfh$-hypercohomology of a variety $X$ with coefficients in $C$ coincides with the étale hypercohomology of $C$ in the cases when either $C$ is a $\mathbb{Q}$-vector space sheaf complex and $X$ is normal or $C$ is a locally constant étale sheaf complex. Hence in this case the étale hypercohomology of $C$ also gives a 'representable' realization.

Note that these realization compute $qfh$-hypercohomology with coefficients in $C$ of any (not necessarily smooth) variety $X$. Hence $M_{gm}(X)_{qfh}$ (i.e., the image of $M_{gm}(X)$ in $DM_{qfh}(k)$) seems to be the natural choice for the $qfh$-motif of a (possibly) singular variety. In particular, its 'standard' realizations have the 'right' values of $H^i_{et}(X, \mathbb{Z}/l\mathbb{Z}(m))$ (at least, in the case when $k$ has finite étale cohomological dimension).

8 Concluding remarks

In subsection 8.1 we give a general description of subcategories of $\mathcal{H}$ generated by fixed sets of objects. In particular, this method can be used to obtain the description of the category of effective Tate motives (i.e., the full triangulated subcategory of $DM^*$ generated by $\mathbb{Z}(n)$ for $n > 0$).

In subsection 8.2 we describe the construction of 'localization of differential graded categories' (due to Drinfeld). This gives us a description of localizations of $\mathcal{H}$. All such localizations come from differential graded functors. As an application, we prove that the motif of a smooth variety is a mixed Tate one.
if and only if its weight complex (as defined in [GiS96], cf. subsection 6.5 and 6.6) is.

In 8.3 we verify that over an arbitrary perfect field one can apply our theory (at least) with rational coefficients. One of the main tools is the Poincare duality in characteristic $p$ proved by Beilinson and Vologodsky. Moreover over finite fields the Beilinson-Parshin conjecture (that $H^i(P, \mathbb{Q}(n))$ for smooth projective $P$ could be non-zero only for $i = 2n$) holds iff $tQ: DM^{eff}_{gm}(\mathbb{Q}) \to K^b(\text{Chow}^{eff}(\mathbb{Q}))$ is an equivalence (note that here $DM^{eff}_{gm}(\mathbb{Q})$, $\text{Chow}^{eff}(\mathbb{Q})$, and $tQ$ denote the corresponding idempotent completions); see Proposition 8.3.1. We also describe an idea for constructing certain ‘infinite integral’ weight complex in finite characteristic (see §7.3 of [Bon10] for a complete proof).

In 8.4 we prove that traces of endomorphisms of cohomology of motives induced by endomorphisms of motives do not depend on the choice of a Weil cohomology theory. This result generalizes Theorem 3.3 of [BlE07].

In 8.5 we remark that one can easily add direct summands of objects to $J$. In particular, one could include $[P][2i](i)$ into $J$.

In 8.6 we consider a functor $m_N: \mathcal{H} \to DM^{eff}$ that maps $[P]$ into the $N$-th canonical truncation of $C(P)$ (as a complex of sheaves).

### 8.1 Subcategories of $\mathcal{H}$ generated by fixed sets of objects

Let $B$ be a set of objects of $\mathcal{H}$; we assume that $B$ is closed with respect to direct sums.

Let $B'$ denote some full additive subcategory of $J' = \text{Pre-Tr}(J)$ such that the corresponding objects of $\mathcal{H}$ are exactly elements of $B$ (up to isomorphism).

Let $\mathcal{B}$ denote the smallest triangulated category of $\mathcal{H}$ containing $B$.

**Proposition 8.1.1.** $\mathcal{B}$ is canonically isomorphic to $\text{Tr}^+(B')$.

**Proof.** Follows immediately from Theorem 1 in §4 of [BoK90].

**Remark 8.1.2.** 1. It follows immediately that in order to calculate the smallest triangulated category of containing an arbitrary fixed set of objects in $\mathcal{H}$ it is sufficient to know morphisms between the corresponding objects in $J'$ (i.e., certain complexes) as well as the composition rule for those morphisms.

2. We obtain that for any triangulated subcategory of $D \subset \mathcal{H}$ the embedding $D \to \mathcal{H}$ is isomorphic to $\text{Tr}^+(E)$ for some differential graded functor $E: F \to G$. Here $G$ is usually equal to $J'$ (though sometimes it suffices to take $G = J$); $F$ depends on $D$.  

60
It follows that for any \( h \in \text{Obj} \mathcal{H} \) the representable contravariant functor \( h^* : D \to \text{Ab} : d \to \mathcal{H}(d, h) \) can be represented as \( H^0(u) \) for some contravariant differential graded functor \( u : F \to B^{-}(\text{Ab}) \). See part 2 Proposition 8.2.2 below for a similar statement for localization functors.

3. Using this statement one can easily calculate the triangulated category of (mixed effective) Tate motives (cf. [Lev05]). It is sufficient to take \( B = \sum_{a_i \geq 0} \left[ (\mathbb{P}^1)^{a_i} \right] \), i.e., the additive category generated by motives of non-negative powers of the projective line. This gives a certain extension of the description of \([\text{Spi}]\) to the case of integral coefficients. Note that the description of the category of effective Tate motives immediately gives a description of the whole category of Tate motives since \( \mathbb{Z}(1) \) is quasi-invertible with respect to \( \otimes \). Besides, one could expand \( J \): see §8.5 below.

8.2 Localisations of \( \mathcal{H} \)

Let \( C \) be a differential graded category satisfying the homotopical flatness condition, i.e., for any \( X, Y \in \text{Obj} C \) all \( C^i(X, Y) \) are torsion-free. Note that both \( J \) and \( J' = \text{Pre-Tr}^+ (J) \) satisfy this condition.

In [Dri04] V. Drinfeld has proved (modifying a preceding result of B. Keller) that for \( C \) satisfying the homotopical flatness condition and any full differential graded subcategory \( B \) of \( C \) there exists a differential graded quotient \( C/B \) of \( C \) modulo \( B \). This means that there exists a differential graded \( g : C \to C/B \) that is surjective on objects such that \( \text{Tr}^+(g) \) induces an equivalence \( \text{Tr}^+(C)/\text{Tr}^+(B) \to \text{Tr}^+(C/B) \) (i.e., \( \text{Tr}^+(C)/\text{Tr}^+(B) \cong \text{Tr}^+(C/B) \), \( \text{Tr}^+(g) \) is zero on \( \text{Tr}^+(B) \) and induces this equivalence).

The objects of \( C/B \) are the same as for \( C \), whereas for \( C_1, C_2 \in \text{Obj} C = \text{Obj}(C/B), \ i \in \mathbb{Z}, \) we define

\[
(C/B)^i(C_1, C_2) = C^i(C_1, C_2) \bigoplus_{j \geq 0} \bigoplus_{B_1, \ldots, B_j \in \text{Obj} \mathcal{B}} C^{a_1}(C_1, B_1) \otimes \varepsilon_{B_1} \otimes C^{a_2}(B_1, B_2) \otimes \varepsilon_{B_2} \cdot \cdot \cdot \otimes \varepsilon_{B_j} \otimes C^{a_j}(B_j, C_2).
\]

Here \( \varepsilon_b \in (C/B)^{-1}(b, b) \) for each \( b \in \text{Obj} B \in \text{Obj}(C/B) \) is a 'canonical new morphism' such that \( d_b \varepsilon_b = id_b; \) \( \varepsilon_b \) spans a canonical direct summand \( \mathbb{Z} \varepsilon_b \subset (C/B)^{-1}(b, b) \). From this condition one recovers the differential on morphisms of \( C/B \).

For example, this construction (for \( C = J \)) gives an explicit description of the localization of \( \mathcal{H} \) by the triangulated category generated by all \([Q], Q \in \text{SmPrVar}, \dim Q < n \), for a fixed \( n \) (and hence also of the corresponding localization of \( DM^* \)).
More generally, for localizations of \( \mathcal{H} \) modulo some \( A \subset \mathcal{H} \) it is sufficient to know the complexes \( C/B([P],[Q]) \) and the composition law for a certain \( B \) and all \( P,Q \in SmPrVar \); here either \( C = J \) or \( C = J'. \) In the case when \( A \) is not generated by objects of (stupid) length 0 we are forced to take \( C = J' \); this makes the direct sum in \( \langle 10 \rangle \) huge.

**Remark 8.2.1.** 1. One can extend \( J \) as in \( \langle 8.5 \rangle \) below. This allows one to obtain a certain description of the (triangulated) category of birational motives; see \([KaS02]\).

2. Explicit calculations by means of \( \langle 10 \rangle \) could be difficult. We will only need (for part 3 of Proposition \( \langle 8.2.2 \rangle \) below) the following obvious property of the construction: if \( C^i(\cdot, \cdot) = 0 \) for \( i > 0 \) then the same is true for \( C/B \). Note also that in this case \( C^0(X,Y) = (C/B)^0(X,Y) \) for all \( X,Y \in \text{Obj}C \); \( H(C/B)(X,Y) \) is a certain easily described factor of \( HC(X,Y) \). These facts immediately yield the formula for \( \text{Hom}(\overline{M}(X),\overline{M}(Y)[i]) \) for \( i \geq 0 \) as described in Corollary 7.9 of \([KaS02]\) (note that loc. cit. is false for \( i < 0 \)); here \( X,Y \in SmPrVar \), \( \overline{M}(X),\overline{M}(Y) \) are their birational motives.

**Proposition 8.2.2.** 1. If \( F : \mathcal{H} \to T \) is a certain localization functor (\( T \) is a triangulated category) then \( F \cong \text{Tr}^+(G) \) for a certain differential graded functor \( G \) from \( J \).

2. For any \( t \in T \) the contravariant functor \( t^* : \mathcal{H} \to \text{Ab} : X \to T(F(x),t) \) can be represented as \( H^0(u) \) for some contravariant differential graded functor \( u : J \to B^{-}(\text{Ab}) \).

3. Let \( B \) be a full additive subcategory of \( J \), \( \text{Obj}B = T \subset SmPrVar \). Let \( \mathfrak{B} \) denote the smallest triangulated subcategory of \( \mathcal{H} \) that contains all objects of \( B \) and is closed with respect to taking direct summands (in \( B \)). Then for \( M \in \text{Obj}\mathcal{H} \) we have \( M \in \text{Obj}\mathfrak{B} \) if and only if \( t_0(M) \) is a direct summand of a complex all whose terms have the form \( [Q], Q \in T \).

**Proof.** 1. Let \( A = \{X \in \text{Obj}\mathcal{H}, F(X) = 0 \} \subset \text{Obj}J' = \text{Obj}\mathcal{H} \), denote the corresponding full subcategory of \( J' \) by \( B' \). By Proposition \( \langle 8.1.1 \rangle \) \( \text{Tr}^+(B') \) is isomorphic to the categorical kernel of \( F \). Let \( H : J' \to J'/B' \) denote the functor given by Drinfeld’s construction. Since \( \text{Tr}^+(J') = \mathcal{H} \), we obtain \( \text{Tr}^+(H) \cong F \). Hence by part 2 of Remark \( \langle 2.3.3 \rangle \) we can take \( G \) being the restriction of \( H \) to \( J \subset J' \).

2. Let \( w \) denote some element that corresponds to \( t \) in \( \text{Pre-}\text{Tr}^+(J'/B') \). Then it suffices to take \( u([P]) = \text{Pre-}\text{Tr}^+(J'/B')(\text{Pre-}\text{Tr}^+(G)([P],w)) \).

3. If \( M \in \text{Obj}\mathfrak{B} \) then \( t_0(M) \) belongs to the triangulated subcategory of \( \mathcal{H}_0 = K^b(\text{Corr}_{rat}) \) that contains all \([Q], Q \in T \) and is closed with respect to taking direct summands. This subcategory consists exactly of complexes described in the assertion 3.
We prove the converse implication.

We can assume that \( t_0(M) \) is homotopy equivalent to a complex all whose terms have the form \([Q], Q \in T\).

Let \( I \) denote \( J/B \), let \( K = Tr^+(I) \). Let \( S : J \to J/B \) be the localization functor of [Dr04]; let \( u = Tr^+(S) \). Since \( I^i(-, -) = 0 \) for \( i > 0 \), we have natural functors \( I \to S(HI) \) (see [2.1]) and \( v : K \to K_0 \), where \( K_0 = K^b(HI) \) (the weight complex functor for this case). Hence we have functors \( u_0 : S_0 \to K_0 \) and \( v : K \to K_0 \) such that \( u_0 \circ t_0 = v \circ u \). We obtain \( v(u(M)) = 0 \).

Suppose that \( M = j(X) \) for some \( X \in \text{Obj} \Theta \). We can also assume that \( X \in \text{Obj} K \).

For any object \( U \in \text{Obj} K = \text{Obj} \text{Pre-Tr}^+(I) \) we consider the (contravariant) differential graded functor \( U^* : J \to B(\text{Ab}) \) that maps \([P] \) to \( \text{Pre-Tr}^+(I)([P], U) \). Then we can consider the spectral sequence (14) for \( Tr^+(U^*): E^1_1(S) \implies Tr^+(U^*)(X[-i - j]) = K(X, U[i + j]) \). As in §7.3 we note that its \( E_1 \)-terms depend only on \( u_0(t_0(X)) \) (they are just \( K_0(u_0(t_0(X)), v(U)[i+j]) \)). Since \( u_0(t_0(X)) = v(u(X)) = 0 \), we have \( Tr^+(U^*)(X) = 0 \) for any \( U \). Since \( Tr^+(U^*)(X) = K(X, U) \), we obtain that \( X \cong 0 \) in \( K \).

Hence \( M \in \text{Obj} \Theta \). \qed

Part 3 is a generalization of part 5 of Theorem [6.2.1] (there \( T = \{0\} \)).

**Corollary 8.2.3.** Let \( X \) belong to \( \text{SinVar} \). Then \( M_{gm}(X) \) is a mixed Tate motif (as described in part 3 of Remark [8.1.2]) in \( D_{eff}^{gm} \) (i.e., we add direct summands) if and only if the complex \( t_0(U) \in K^b(\text{Chow}^{eff}) \) is.

**Proof.** We apply part 3 of Proposition [8.2.2] for \( T = \{\sqcup \mathbb{N}, \mathbb{P}^1\} \).

We obtain that \( M_{gm}^c(X) \) is a mixed Tate motif if and only if \( t_0(M_{gm}^c(X)) = W(X) \) is mixed Tate as an object of \( K^b(\text{Chow}^{eff}) \).

On the category of geometric of Voevodsky’s motives \( D_{gm} \supset D_{eff}^{gm} \) (see §3.3 of this paper and §4.3 of [Voe00]) we have a well-defined duality such that \( Z(n)^* = Z(-n) \). Therefore the category of mixed Tate motives is a self-dual subcategory of \( D_{gm} \). Since \( M_{gm}(X)^* = M_{gm}^c(X)(-n)[-2n], n = \dim X \) (see Theorem 4.3.7 of [Voe00]); we can assume that \( X \) is equidimensional), we obtain that \( M_{gm}(X) \) is a Tate motif if and only if \( M_{gm}^c(X) \) is. \qed

One can translate this statement into a certain condition on the motives \( M_{gm}(Y_{i_1} \cap Y_{i_2} \cap \cdots \cap Y_{i_r}) \) (in the notation of Proposition [6.5.1]).
8.3 Motives in finite characteristic; $t \otimes \mathbb{Q}$ is (conditionally) an isomorphism over a finite field

In this subsection we consider Voevodsky’s motives over an arbitrary perfect field $k$.

In the proof of Theorem 3.1.1 we used two facts:

(i) The cohomology of Suslin complex of a smooth projective variety coincides with its hypercohomology.

(ii) Motives of smooth projective varieties generate $DM^*$.

To the knowledge of the author, neither of these facts is known in finite characteristic.

Yet for covering of any variety over any perfect field one has the Mayer-Vietoris triangle (see Proposition 4.1.1 of [Voe00a]); one also has the blow-up distinguished triangle (see Proposition 3.5.3 of [Voe00a] and Proposition 5.21 of [Voe00b]). Besides, for a closed embedding of smooth varieties one has the Gysin distinguished triangle (see [Deg06]).

8.3.1 Certain integral arguments

In [BeV08] it was proved unconditionally that $DM^*$ has a differential graded enhancement. In fact, this follows rather easily from the localization technique of Drinfeld described in subsection 8.2 along with Voevodsky’s description of $DM^*$ as a localization of $K^b(\text{SmCor})$. Moreover, Proposition 6.7 of [BeV08] extends the Poincare duality for Voevodsky motives to our case. Therefore for $P, Q \in \text{SmPrVar}$ we obtain

$$DM^*(\text{M}_{gm}(P), \text{M}_{gm}(Q)[i]) = \text{Corr}_{rat}(\{P\}, \{Q\})$$

for $i = 0$; 0 for $i > 0$.

Hence the triangulated subcategory $DM_{pr}$ of $DM^*$ generated by $\{P\}$, $P \in \text{SmPrVar}$ can be described as $\text{Tr}(I)$ for a certain negative differential graded $I$ (see part 2 of Remark 2.7.4). Note also that the complexes $I(P, Q)$ compute motivic cohomology of $P \times Q$.

If we define the categories $I_N$ similarly to $J_N$ (see subsection 6.1) then $I_0 = \text{Corr}_{rat}$. Hence there exists a conservative weight complex functor $t_0 : DM_{pr} \to K^b(\text{Corr}_{rat})$. Moreover, for any ‘enhanceable’ realization of $DM_{pr}$ (again one can easily check that these include motivic cohomology and étale cohomology) and any $X \in \text{ObjDM}_{pr}$ one has the motivic descent spectral sequence (14).

The problem is that (to the knowledge of the author) at this moment there is no way to prove that $DM_{pr}$ contains the motives of all varieties (though it certainly contains the motives of varieties that have ‘smooth projective stratification’).
Yet for any variety $X$ one could consider the functor $X^*_pr$ that equals $DM^{eff}_{gm}(-, M_{gm}(X))$ restricted to $DM_{pr}$. It has a differential graded 'enhancement'; in §7.3 of [Bon10] we prove that $X^*_pr$ is representable by (at least) an object of a certain infinite analogue of $DM_{pr}$. This gives a (possibly, infinite) weight complex for $X$.

### 8.3.2 Rational arguments

For rational coefficients (ii) was proved in Appendix B of [HuK06]: it suffices to note that if there exists an étale finite morphism $U \to V$ for smooth $U, V$ then $M_{gm}(V) \otimes \mathbb{Q}$ is a direct summand of $M_{gm}(U) \otimes \mathbb{Q}$. Hence the existence of de Jong’s alterations (see [dJo06]) yields (ii) for motives with rational coefficients (up to an idempotent completion of categories).

Hence we obtain that in the characteristic $p$ case the category $DM^{eff}_{gm} \otimes \mathbb{Q}$ is the idempotent completion of $Tr(I)$ for a certain negative differential graded $I$ (see above). Moreover (by the same arguments as in the characteristic 0 case) there exists a conservative weight complex functor $t\mathbb{Q} : DM^{eff}_{gm} \otimes \mathbb{Q} \to \text{K}^b(\text{Chow}^{eff}_{gm})$.

Now we show that, in contrast to the characteristic 0 case, over finite fields the Beilinson-Parshin conjecture (see below) implies that $t\mathbb{Q}$ is an equivalence.

**Proposition 8.3.1.** Let $k$ be a finite field.

Suppose that for any $X \in \text{SmVar}$ the only non-zero cohomology group $H^i(X, \mathbb{Q}(n))$ is $H^{2n}$.

Then $t\mathbb{Q}$ is an equivalence of categories.

**Proof.** By Theorem 4.2.2 of [Voe00a] (note that it is valid with rational coefficients in our case also!) for any $P, Q \in \text{SmPrVar}, i \in \mathbb{Z}$ we have

$$DM^{eff}(M_{gm}(P) \otimes \mathbb{Q}, M_{gm}(Q) \otimes \mathbb{Q}[i]) = H^{i+2r}(P \times Q, \mathbb{Q}(r)),$$

where $r$ is the dimension of $Q$. Therefore, if the Beilinson-Parshin conjecture holds then

$$DM^{eff}(M_{gm}(P) \otimes \mathbb{Q}, M_{gm}(Q) \otimes \mathbb{Q}[i]) = \text{Corr}_{rat} \otimes \mathbb{Q}([P], [Q])$$

for $i = 0$; 0 otherwise.

We obtain

$$DM^* \otimes \mathbb{Q}([P], [Q][i]) \cong K^*(\text{Corr}_{rat} \otimes \mathbb{Q})(t_0 \otimes \mathbb{Q}([P]), t_0 \otimes \mathbb{Q}([Q][i]))$$

for all $i \in \mathbb{Z}$. Since $[P]$ for $P \in \text{SmPrVar}$ generate $DM^* \otimes \mathbb{Q}$ as a triangulated category, the same easy standard reasoning as the one used in the proof of
Theorem 3.1.1 shows that $t_0 \otimes \mathbb{Q}$ induces a similar isomorphism for any two objects of $DM^s \otimes \mathbb{Q}$; hence $t_0 \otimes \mathbb{Q}$ is a full embedding. Since $[P], P \in SmPrVar$ generate $K^b(Corr_{rat} \otimes \mathbb{Q})$ as a triangulated category, we obtain that $t_0 \otimes \mathbb{Q}$ is an equivalence of categories. Lastly, since $DM^{eff}_{gm} \otimes \mathbb{Q}$ is the idempotent completion of $DM^s \otimes \mathbb{Q}$ and $K^b(Corr_{rat} \otimes \mathbb{Q})$ is the idempotent completion of $K^b(Corr_{rat} \otimes \mathbb{Q})$, $t\mathbb{Q}$ is an equivalence also.

Remark 8.3.2. 1. Obviously, the converse statement holds also: if $t\mathbb{Q}$ is an isomorphism then $DM^{eff}_{gm} \otimes \mathbb{Q}$, $M_{gm}\otimes \mathbb{Q} \otimes \mathbb{Q}[i]) = 0$ for $i \neq 0$, $P, Q \in SmVar$; hence the Beilinson-Parshin conjecture holds.

2. As it was noted in Remark 8.3.2 using $t\mathbb{Q}$ one can obtain a functor $t_{num} : DM^{eff}_{gm} \rightarrow K^b(Mot^{eff}_{num})$ (the 'wrong' homotopy category of effective numerical motives). Over a finite field we can use Kunneth projectors for numerical motives (cf. §2 of [MiR]; note that the projectors are functorial!) to replace $K^b(Mot^{eff}_{num})$ by the 'correct' category $K^b(M)$ such that $M$ is tannakian, $H_i(P)$ (the $i$-th homological component) is put in degree $i$. Moreover, the 'standard' conjectures assumed in Theorem 5.3 of [MiR] (Tate conjecture + numerical equivalence coincides with rational equivalence) imply that $t_{num}$ can be extended to an equivalence of $DM_{gm} \otimes \mathbb{Q}$ with the motivic $t$-category of Theorem 5.3 of [MiR] (see also Theorem 56 of [Kah05]). The relation between different conjectures is discussed in 1.6.5 of [Kah05].

8.4 An application: independence on $l$ for traces of open correspondences

Our formalism easily implies that for any $X \in ObjDM^{eff}_{gm}$ and any $f \in DM^{eff}_{gm}(X, X)$ the trace of the map $f^*$ induced on the (rational) $l$-adic étale cohomology $H(X)$ does not depend on $l$. This gives a considerable generalization of Theorem 3.3 of [Bie07] (see below).

Now we formulate the main statement more precisely. In this subsection we do not demand the characteristic of $k$ to be 0.

Proposition 8.4.1. Let $H$ denote any of rational $l$-adic étale cohomology theories or the singular cohomology corresponding to any embedding of $k$ into $\mathbb{C}$ (in characteristic 0). Denote by $Trf^*_H$ the sum $(-1)^iTarf_{H(X)}$.

Then $Trf^*_H$ does not depend on the choice of $H$.

Proof. This statement is well known for Chow motives. Now we reduce everything to this case.

We consider the weight spectral sequence $S$ for $H(X)$ (see §7.3 and part 2 of Remark 7.3.1). Recall that $S$ is functorial in $H$ and $DM^{eff}_{gm}$-functorial in $X$. Hence any $f$ induces a (unique) endomorphism $f^*_S$ of $S$. To construct $f^*_S$
one could also use the spectral sequence $T$ described in Remark 7.4.1. Hence to reduce the statement to the case of Chow motives it suffices to apply the following formula (that follows immediately from the general spectral sequence formalism):

$$Trf_H^* = \sum_{i,j} -1^{i+j} f_H^{*}(p^j);$$

\[ (18) \]

see III.7.4c of [GeM02].

Note that, as we have shown above, these rational arguments also work in finite characteristic.

Now, Theorem 3.3 of [BlE07] states the independence from the choice of $H$ of traces of maps induced by open correspondences on the cohomology of $U \in SmVar$ with compact support. Open correspondences and the corresponding cohomology maps were described in Definition 3.1 loc. cit. We will not recall this definition here; we will only note that the map $\Gamma^*$ of loc. cit. comes from a certain $f \in DM^{eff}_{gm}(M_{gm}(U), M_{gm}(U))$. Indeed, $\Gamma^*$ was defined as a composition $(p_1)_* \circ (p_2)^*$ (in the notation of [BlE07]). One can define the morphism of motives corresponding to $(p_2)^*$ using the functoriality of $M^c_{gm}$ with respect to proper morphisms (see §4.1 of [Voe00a]). To define the morphism corresponding to $(p_1)_*$ one should use Corollary 4.2.4 loc. cit.

It follows that we have generalized Theorem 3.3 of [BlE07] considerably. Indeed, we do not demand $U$ to be a complement of a smooth projective variety by a strict normal crossing divisor. This is especially important in the characteristic $p$ case. Besides, it seems that open correspondences of the type considered in Theorem 2.8 ibid. also give endomorphisms of $M^c_{gm}(U)$.

Remark 8.4.2. 1. Certainly, exactly the same argument proves the independence from $H$ of $n_\lambda(H) = (-1)^i n_\lambda f^*_H(iX); \text{here } n_\lambda f^*_H(iX)$ for a fixed algebraic number $\lambda$ denotes the algebraic multiplicity of the eigenvalue $\lambda$ for the operator $f^*_H(iX)$.

2. In fact, all these statements follow easily from the following statement: the appropriately defined group $K_0(End Chow^{eff})$ surjects onto $K_0(End DM^{eff}_{gm})$; see §5.4 of [Bon10] for details.

8.5 Adding kernels of projectors to $J$

The description of the derived category of Tate motives and of the Tate twist on $\mathcal{H}$ (see §3.3) would be better if $Z(i)$, $i \geq 0$ would be motives of length 0 (see part 3 of Remark 8.1.2 and subsection 6.2). To this end we show that one can easily add direct summands of objects to $J$. This means...
that we consider a differential graded category $J^+$ whose objects are $\{(j, p) : j \in \text{Obj} J, p \in J^0(j, j), j^2 = j\}$. Its morphisms are defined as usually for idempotent completions, i.e., $J^+(j, p), (j', p')) = j' \circ J(j, j') \circ p$.

Indeed, if the cohomology of a complex of sheaves coincides with its hypercohomology, the same is true for any direct summand of this complex. Therefore, if $D, D'$ are direct summands (in $C^-(\text{Shv}(\text{SmCor}))$) of $C(P), C(P')$ respectively, $P, P' \in \text{SmPrVar}$, then the natural analogue of Proposition 1.3.1 will be valid for $\text{DM}^\text{eff}_{-i}(p(D), p(D'))$. It easily follows that $m$ can be extended to a full embedding of $\text{Tr}(J^+)$ into $\text{DM}^\text{eff}$ (cf. Theorem 3.1.1).

In particular, let $P \subset Q \in \text{SmPrVar}$ and let there exist a section $j : Q \rightarrow P$ of the inclusion. Then the cone of $j$ naturally lies in $J^+$ (note that the cone is isomorphic to $m^{-1}(M^\text{gm}_{i}(Q - P))$).

For example, one can present $[\mathbb{P}^1]$ as $[pt] \oplus \mathbb{Z}(1)[2]$. Hence for $P \in \text{SmPrVar}$, $i \geq 0$ one could consider $P[2i](i)$ as an object of $J^+$ (cf. the reasoning in the proof of part 1 of Theorem 6.2.1 and part 3 of Remark 8.1.2).

Yet this method (most probably) cannot give a (canonical) differential enhancement of the whole $\text{DM}^\text{eff}_{-i}(\text{SmPrVar})$. To obtain an enhancement for it one could apply the ‘infinite diagram’ method of Hanamura (see §2 of [Han95]).

8.6 The functors $m_N$

We consider the functor $J_N \rightarrow B^-(\text{Shv}(\text{SmCor}))$ that maps $[P]$ into $\text{SC}_N(P)$. Here $\text{SC}_N(P)$ is the Nisnevich sheafification of the presheaf $C_N(P)(-)$(they coincide for $i \neq -N$). We consider the corresponding functor $h_N : \mathcal{H}_N \rightarrow K^-(\text{Shv}(\text{SmCor}))$ and $m_N = p \circ h_N$. Note that for any $X \in \text{Obj} \mathcal{H}_N$ we have $m_N(X) \in \text{DM}^\text{eff}_{-i}$. By part 1 of Proposition 2.7.2 the natural morphisms $C_P \rightarrow \text{SC}_N(P)$ in $K^-(\text{Shv}(\text{SmCor}))$ induce a transformation of functors $\text{Tr}_N : m \rightarrow m_N$. Besides $\text{tr}_N$ for any $X \in \mathcal{H}$ is induced by a canonical map in $K^-(\text{Shv}(\text{SmCor}))$.

It seems that no nice analogue of part 3 of Theorem 6.2.1 is valid for $m_N$. Yet for low-dimensional varieties $m_N$ coincides with $m$.

Proposition 8.6.1. Suppose that the Beilinson-Soulé vanishing conjecture holds over $k$. Then $m_{2n}(X) \cong m(X)$ in $\text{DM}^\text{eff}_{-i}$ if the dimension of $X$ is $\leq n$.

Proof. We check by induction on $n$ that $\text{tr}_{2n}$ is the identity for $m(X)$. This is obviously valid for $n = 0$. 

68
Applying the same reasoning as in the proof of part 1 of Theorem 6.2.1 we obtain that it is sufficient to prove the assertion for smooth projective $X$ of dimension $\leq n$.

It is sufficient to check that $\text{DM}_{\text{eff}}^-(M_{gm}(Y)[N], M_{gm}(X)) = 0$ for any $Y \in \text{SmVar}$, $N \geq 2n$.

By Theorem 4.3.2 of [Voe00a] if the dimension of $X$ equals $n$ then we have $\text{Hom}_{\text{DM}_{\text{eff}}^-(M_{gm}(X), Z(n)[2n])} \cong M_{gm}(X)$. Hence

$$\text{DM}_{\text{eff}}^-(M_{gm}(Y)[N], M_{gm}(X)) = \text{DM}_{\text{eff}}^-(M_{gm}(Y \times X)[N], Z(n)[2n])$$

$$= \text{DM}_{\text{eff}}^-(M_{gm}(Y \times X)[N - 2n], Z(n)).$$

It remains to note that by the Beilinson-Soulé conjecture $\text{DM}_{\text{eff}}^-(M_{gm}(Y \times X), Z(n)[i]) = 0$ for $i < 0$. \hfill \Box

Remark 8.6.2. 1. We also see that for $k$ of characteristic 0 and any $N$ there exist $P, Q \in \text{SmPrVar}$ such that $\mathcal{F}(P[N], [Q]) \neq 0$. Hence none of $t_N$ and $m_N$ are full functors.

2. It can be also easily checked that $tr_{2n}$ being identical for all $X$ of dimension $\leq n$, $n \in \mathbb{Z}$, implies the Beilinson-Soulé conjecture.
