Abstract

Aims Concern has been raised that treatment with angiotensin-converting enzyme inhibitors and angiotensin receptor blockers may increase the expression of angiotensin-converting enzyme 2 (ACE2), which acts as the entry receptor for SARS-CoV-2, and lead to an increased risk of death from SARS-CoV-2. We aimed to address this concern by evaluating the in vivo relationship of treatment with ACE inhibitors and angiotensin receptor blockers (ARB) with circulating plasma concentrations of ACE2 in a large cohort of patients with established cardiovascular disease (n = 1864) or cardiovascular risk factors (n = 2144) but without a history of heart failure.

Methods and results Angiotensin-converting enzyme 2 was measured in 4008 patients (median age 68, 33% women, 31% on ACE-inhibitors, 31% on ARB) using the SOMAscan proteomic platform (SomaLogic Inc, Colorado, USA). Plasma concentration of ACE2 was comparable in 1250 patients on ACE inhibitors (mean 5.99) versus patients without ACE inhibitors (mean 5.98, P = 0.54). Similarly, plasma concentration of ACE2 was comparable in 1260 patients on ARB (mean 5.99) versus patients without ARB (mean 5.98, P = 0.50). Plasma concentration of ACE2 was comparable in 2474 patients on either ACE inhibitors or ARB (mean 5.99) versus patients without ACE inhibitors or ARB (mean 5.98, P = 0.31). Multivariable quantile regression model analysis confirmed the lack of association between treatment with ACE inhibitors or ARB and ACE2 concentrations. Body mass index showed the only positive association with ACE2 plasma concentration (effect 0.015, 95% confidence interval 0.002 to 0.028, P = 0.024).

Conclusions In a large cohort of patients with established cardiovascular disease or cardiovascular risk factors but without heart failure, ACE inhibitors and ARB were not associated with higher plasma concentrations of ACE2.

Background

The majority of deaths from the new severe acute respiratory syndrome coronavirus (SARS-CoV-2) occurred in patients with cardiovascular disease, who often were on chronic treatment with angiotensin converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARB). This epidemiological association together with experimental evidence that treatment with ACE inhibitors and ARB may increase the expression of angiotensin-converting enzyme 2 (ACE2), which acts as the entry receptor for SARS-CoV-2, has led to concern that ACE inhibitors and ARB may causally contribute to an increased risk of death from SARS-CoV-2 via increasing ACE2.

Aims

We aimed to address this concern by evaluating the in vivo effect of treatment with ACE inhibitors and ARB on circulating plasma concentrations of ACE2 in a large cohort of patients with established cardiovascular disease (n = 1864) or cardiovascular risk factors (n = 2144), but without a history of heart failure (NCT01838148, ClinicalTrials.gov).

Methods

This analysis was performed in a large prospective diagnostic study (ClinicalTrials.gov, NCT01838148) designed to advance the early detection of inducible myocardial ischaemia. Consecutive adult patients with symptoms possibly related to inducible myocardial ischaemia, who were referred for stress and rest myocardial perfusion imaging with single-photon emission computed tomography combined with computed tomography (MPI-SPECT/CT) to the University Hospital Basel (Basel, Switzerland), were recruited. All patients provided written informed consent. Clinical information, including patient characteristics, medication, symptoms, and cardiovascular history, was documented by physicians using standardized questionnaires and all medical files available. The study was approved by the local ethics committee and carried out according to the principles of the Declaration of Helsinki.

Of the 4219 patients enrolled in the study, ACE2 was measured in 4008 patients (median age 68 [interquartile range 60 to 76], 33% women, 31% on ACE inhibitors, 31% on ARB, baseline characteristics; see Table 1) using the SOMAscan proteomic platform version 4 (SomaLogic Inc, Colorado, USA). In brief, SOMAscan uses a proprietary DNA-based aptamer technology to bind to the target protein with high specificity and sensitivity.
specificity and transforms individual protein concentrations into a corresponding modified aptamer concentration. Therefore, resulting concentrations [relative fluorescent units (RFU)] are relative and directly proportional to the amount of target protein in the initial sample. Additional analytical validation was performed in this study by utilizing routine cardiovascular biomarker measurements [n-terminal pro-B-type natriuretic peptide (NT-proBNP), Spearman $\rho = 0.63$ and growth differentiation factor 15 (GDF-15), Spearman $\rho = 0.93$, both $P < 0.001$, both Roche Diagnostics] for correlation analysis with SOMAscan results. The natural logarithm of ACE2 measurements was used for all analyses.

**Results**

Plasma concentration of ACE2 was comparable in 1250 patients on ACE inhibitors (mean 5.99) versus patients without ACE inhibitors (mean 5.98, $P = 0.54$; Figure 1). Similarly, plasma concentration of ACE2 was comparable in 1260 patients on ARB (mean 5.99) versus patients without ARB (mean 5.98, $P = 0.50$). Also, plasma concentration of ACE2 was comparable in 2474 patients on either ACE inhibitors or ARB (mean 5.99) versus patients without ACE inhibitors or ARB (mean 5.98, $P = 0.31$).

Multivariable quantile regression model analysis adjusted for age, sex, body mass index, history of atrial fibrillation, diabetes, arterial hypertension, chronic obstructive pulmonary disease, myocardial infarction, coronary artery disease, percutaneous coronary intervention, and coronary artery bypass graft confirmed the lack of association between treatment with ACE inhibitors or ARB and ACE2 concentrations.

Body mass index was positively associated with ACE2 plasma concentration (effect 0.015, 95% CI: 0.002 to 0.028, $P = 0.024$), while age ($-0.045$, 95% CI: $-0.065$ to $-0.034$, $P < 0.001$), history of atrial fibrillation ($-0.034$, 95% CI: 0.062 to $-0.066$, $P = 0.024$), history of PCI ($-0.041$, 95% CI: 0.080 to $-0.001$, $P = 0.042$), and history of CABG ($0.052$, 95% CI: $-0.081$ to $-0.022$, $P < 0.001$) were all negatively associated with ACE2 concentrations in the model.

**Discussion/conclusion**

This large observational study found no association between treatment with ACE inhibitors and/or ARB and circulating plasma concentrations of ACE2 in patients with established cardiovascular disease or cardiovascular risk factors, but without overt heart failure, representing the population most severely affected by SARS-CoV-2. This finding extends and corroborates similar observations regarding the lack of associations between treatment with ACE inhibitors and/or ARB on ACE2 plasma concentrations in two independent cohorts of patients with overt heart failure. $^{1,2}$ The first study included
and the ACE2 aptamer speci-
cordance with proteome and transcriptome measurements
that SOMAscan measurements were shown to be largely in
standard for plasma ACE2 analysis. Therefore, it is reassuring
matography coupled to mass spectrometry is the gold stan-
potentially more so in men than in women. Overall, these
biomarker studies are in agreement with observational
clinical studies documenting a lack of increased risk of severe
illness in patients with COVID-19 treated with an ACE inhibi-
or or ARB. However, ACE2 regulation by RAAS blockade
might be different in patients with active COVID-19 com-
pared with patients without, and further research is needed
on this topic.

Taken together with emerging epidemiological data, the
three in vivo studies on ACE2 plasma concentrations support
the concept that treatment with ACE inhibitors or ARB should
not be withheld from patients at risk for infection with SARS-
CoV-2, although this will need to be ultimately clarified by
clinical trials.

Some limitations should be considered. First, liquid chro-
matography coupled to mass spectrometry is the gold stan-
dard for plasma ACE2 analysis. Therefore, it is reassuring
that SOMAscan measurements were shown to be largely in
accordance with proteome and transcriptome measurements
and the ACE2 aptamer specifically has been validated. Sec-
ond, like previous studies, we measured circulating ACE2 plasma concentrations. The equilibrium between circulating
and membrane-bound ACE2 remains, to our knowledge, incom-
pletely understood.

In conclusion, in a large cohort of patients with established
cardiovascular disease or cardiovascular risk factors but
without heart failure, ACE inhibitors and ARB were not asso-
ciated with higher plasma concentrations of ACE2.

Conflict of interest

Dr. Zimmermann reports research grants from the Freiwillige
Akademische Gesellschaft Basel. Dr. Walter reports research
grants from the Swiss Heart Foundation (FF19097 and
F181111) and the Swiss Academy of Medical Sciences and
Bangerter Foundation. Dr. Mueller has received research
grants from the Swiss National Science Foundation, the Swiss
Heart Foundation, the KTI, the European Union, the Cardio-
vascular Research Foundation Basel, the University Hospital
Basel, Abbott, Astra Zeneca, Beckman Coulter, Biomerieux,
BRAHMS, Critical Diagnostics, Roche, Siemens, Singulex, and
Spingotec, as well as speaker/consulting honoraria from Ab-
bott, Alere, Astra Zeneca, Bayer, Biomerieux, Boehringer
Ingelheim, BMS, BRAHMS, Cardiorentis, Novartis, Roche,
Sanofi, Siemens, and Singulex. All other authors declare that
they have no conflict of interest with this study. All authors
critically reviewed the manuscript and approved the final
version for submission. The sponsors had no role in the design
and conduct of the study; collection, management, analysis,
and interpretation of the data; preparation or approval of
the manuscript.
