LOW WEIGHT MULTIPLE ZETA VALUES CYCLES.

ISMAEL SOUDÈRES

Abstract. In a recent work, the author has constructed two families of algebraic cycles in Bloch cycle algebra over $\mathbb{P}^1 \setminus \{0, 1, \infty\}$ that are expected to correspond to multiple polylogarithms in one variable and have a good specialization at 1 related to multiple zeta values.

This is a short presentation, by the way of toy examples in low weight ($\leq 5$), of this construction and could serve as an introduction to the general setting. Working in low weight also makes it possible to push (“by hand”) the construction further. In particular, we will not only detail the construction of the cycle but we will also associate to these cycles explicit elements in the bar construction over the cycle algebra and make as explicit as possible the “bottom-left” coefficient of the Hodge realization periods matrix. That is, in a few relevant cases we will associated to each cycles an integral showing how the specialization at 1 is related to multiple zeta values. We will be particularly interested in a new weight 3 example corresponding to $-2\zeta(2, 1)$.

This work has been partially supported by DFG grant SFB/TR45 and by Prof. Levine Humbolt Professorship. I would like to thank P. Cartier for his attention to my work and H. Gangl for all his help, his comments and his stressing demand for me using tree related structures which allowed me to understand the Lie-like underlying combinatorics. Finally, none of this would have been possible without M. Levine patience, his explanations and deep inputs. This paper has been finalized during my stay at the MPIM and I am grateful to the MPI for providing ideal working conditions and support.
1. Introduction

The multiple polylogarithm functions were defined in [Gon95] by the power series

\[ \text{Li}_{k_1, \ldots, k_m}(z_1, \ldots, z_m) = \sum_{n_1 > \cdots > n_m} \frac{z_1^{n_1} \cdots z_m^{n_m}}{n_1^{k_1} \cdots n_m^{k_m}} \quad (z_i \in \mathbb{C}, |z_i| < 1). \]

They admit an analytic continuation to a Zariski open subset of \( \mathbb{C}^m \). The case \( m = 1 \) is nothing but the classical polylogarithm functions. The case \( z_1 = z \) and \( z_2 = \cdots = z_m = 1 \) gives a one variable version of multiple polylogarithm functions

\[ \text{Li}_{k_1, \ldots, k_m}^c(z) = \text{Li}_{k_1, \ldots, k_m}(z, 1, \ldots, 1) = \sum_{n_1 > \cdots > n_m} \frac{z^{n_1}}{n_1^{k_1} \cdots n_m^{k_m}}. \]

When \( k_1 \) is greater or equal to 2, the series converge as \( z \) goes to 1 and one recovers the multiple zeta value

\[ \zeta(k_1, \ldots, k_m) = \text{Li}_{k_1, \ldots, k_m}^c(1) = \text{Li}_{k_1, \ldots, k_m}(1, \ldots, 1) = \sum_{n_1 > \cdots > n_m} \frac{1}{n_1^{k_1} \cdots n_m^{k_m}}. \]

To the tuple of integer \((k_1, \ldots, k_m)\) of weight \( n = \sum k_i \), we can associate a tuple of 0 and 1

\[ (\varepsilon_n, \ldots, \varepsilon_1) := (0, \ldots, 0, 1, \ldots, 0, \ldots, 0, 1) \]

which allows to write multiple polylogarithms as iterated integrals \((z_i \neq 0 \text{ for all } i)\):

\[ \text{Li}_{k_1, \ldots, k_m}(z_1, \ldots, z_m) = (-1)^m \int_{\Delta_n} \frac{dt_1}{t_1 - \varepsilon_1 x_1} \wedge \cdots \wedge \frac{dt_m}{t_m - \varepsilon_m x_n} \]

where \( \gamma \) is a path from 0 to 1 in \( \mathbb{C} \setminus \{x_1, \ldots, x_n\} \), the integration domain \( \Delta_n \) is the associated real simplex consisting of all \( m \)-tuples of points \((\gamma(t_1), \ldots, \gamma(t_n))\) with \( t_i < t_j \) for \( i < j \) and where we have set \( x_n = z_1^{-1}, x_{n-i} = (z_1 \cdots z_i)^{-1} \) for \( k_1 + \cdots + k_{i-1} + 1 \leq i < k_1 + \cdots + k_l \) and \( x_1 = (z_1 \cdots z_m)^{-1} \).

Bloch and Kriz in [BK94] have constructed an algebraic cycle avatar of the classical polylogarithm function. More recently in [GGL09], Gangl, Goncharov and Levin, using a combinatorial approach, have built algebraic cycles corresponding to the multiple polylogarithm values \( \text{Li}_{k_1, \ldots, k_m}(z_1, \ldots, z_m) \) with parameters \( z_i \) under the condition that the corresponding \( x_i \) (as defined above) are all distinct. In particular, all the \( z_i \) but \( z_1 \) have to be different from 1 and their methods does not give algebraic cycles corresponding to multiple zeta values.

The goal of the article [Sou12] was to develop a geometric construction for multiple polylogarithm cycles removing the previous obstruction which will allows to have multiple zeta cycles.

A general idea underlying this project consist on looking cycles fibered over a larger base and not just point-wise cycles for some fixed parameter \((z_1, \ldots, z_m)\). Levine in [Lev11] shows that there exist a short exact sequence relating the Bloch-Kriz Hopf algebra over \( \text{Spec}(K) \), its relative version over \( \mathbb{P}^1 \setminus \{0, 1, \infty\} \) and the Hopf algebra associated to Goncharov and Deligne’s motivic fundamental group over \( \mathbb{P}^1 \setminus \{0, 1, \infty\} \) which contains motivic avatars of iterated integral associated to the multiple polylogarithms in one variable.

As this one variable version of multiple polylogarithms gives multiple zeta values for \( z = 1 \), it is natural to investigate first the case of Bloch-Kriz construction over \( \mathbb{P}^1 \setminus \{0, 1, \infty\} \) in order to obtain algebraic cycle corresponding to multiple polylogarithms in one variable with a “good specialization” at 1.

This paper presents the main geometric tools in order to construct such algebraic cycle and applies the general construction described in [Sou12] to low weight.
examples up to weight 5. In these particular cases, one can easily go further in
the description, lifting the obtained cycles to the bar constructions over Bloch cy-
cle algebra, describing the corresponding Bloch-Kriz motive and computing some
associated integrals related to the Hodge realization. Those integrals gives back
multiple polylogarithms in one variable and their specialization at 1 give multiple
zeta values.

The structure of the paper is organized as follows. In section 2 we review shortly
the combinatorial context as it provides interesting relations for the “bar” elements
associated to the cycles and an interesting relation with Goncharov motivic coprod-
uct for motivic iterated integrals. Section 3 is devoted to the geometric situation
and building the cycles after a presentation of Bloch cycle algebra. In Section 4,
I present a combinatorial representation of the constructed cycles as parametrized
cycles.

Section 5, recalls the definition of the bar construction over a commutative differ-
ential algebra and associates elements in the bar constructions (and a corresponding
motive in Bloch-Kriz construction) to the low weight examples of cycles. Finally in
section 6, I follow Gang, Goncharov and Levine algorithm associating an integral
to some of the low weight algebraic cycles previously described.

2. Combinatorial situation

In this paper a tree is a finite tree whose internal vertices have valency \( \geq 3 \) and
where at each vertex a cyclic ordering of the incident edges is given. A rooted tree
have a distinguished external vertex called the root and a forest is a disjoint union
of trees.

Trees will be drawn with the convention that the cyclic ordering of the edges
around internal vertex is displayed in counterclockwise direction. The root vertex
in the case of a rooted tree is display at the top.

2.1. Trees, Lie algebra and Lyndon words. Let \( T^{tri} \) be the \( \mathbb{Q} \)-vector space
generated by rooted trivalent trees with leaves decorated by 0 and 1 modulo the
relation
\[
T_1 T_2 T_3 = - T_1 T_3 T_2.
\]

Define on \( T^{tri} \) the internal law \( \langle \rangle \) by
\[
\begin{align*}
T_1 \langle T_2 \rangle & = - \langle T_1 T_3 \rangle , \\
\langle T_1 T_2 \rangle & = - \langle T_3 \rangle , \\
T_1 \langle T_3 \rangle & = - \langle T_2 \rangle , \\
\langle T_1 T_2 T_3 T_4 \rangle & = - \langle T_1 T_2 \rangle T_3 T_4 .
\end{align*}
\]

and extend it by bilinearity. One remarks that by definition \( \langle \rangle \) is antisymmetric.
Identifying \( \{0, 1\} \) to \( \{X_0, X_1\} \) by the obvious morphism and using the correspon-
dence \( \langle \rangle \leftrightarrow [\cdot, \cdot] \), this internal law allows us to identity the free Lie algebra \( \text{Lie}(X_0, X_1) \)
with \( T^{tri} \) modulo the Jacobi identity. Thus, one can identity the (graded) dual of
\( \text{Lie}(X_0, X_1) \) as a subspace of \( T^{tri} \)
\[
\text{Lie}(X_0, X_1)^* \subset T^{tri}.
\]

A Lyndon word in 0 and 1 is a word in 0 and 1 strictly smaller than any of its
no empty proper right factor for the lexicographic order with 0 < 1. The standard
factorization \( [W] \) of a Lyndon word \( W \) is defined inductively by \([0] = X_0, [1] = X_1\)
and otherwise by \([W] = [[U], [V]]\) with \( W = UV, U \) and \( V \) nontrivial such that \( V \)
is minimal. The sets of Lyndon brackets \( \{[W]\} \), that is Lyndon words in standard
factorization, forms a basis of \( \text{Lie}(X_0, X_1) \) which can then be used to write the Lie bracket

\[
[[U], [V]] = \sum_{W \text{ Lyndon words}} \alpha_{U,V}^W [W].
\]

with \( U < V \) Lyndon words.

**Example 2.1.** Lyndon words in letters \( 0 < 1 \) in lexicographic order are up to weight 5:

\[
0 < 00001 < 0001 < 00011 < 00101 < 001 < 0011 < 00111 < 01 < 01011 < 011 < 0111 < 01111 < 1
\]

The above identification between \( \text{Lie}(X_0, X_1) \) as a quotient of \( T^{tri} \) and the basis of Lyndon brackets allows us to define a family of trees dual to the Lyndon bracket basis beginning with \( T_0^* = \frac{0}{0} \) and \( T_1^* = \frac{1}{1} \) and then setting

\[
T_{W^*} = \sum_{U < V} \alpha_{U,V}^W T_U^* T_V^*.
\]

**Example 2.2.** We give below the corresponding dual trees in weight 1, 2 and 3

\[
T_0^* = \frac{0}{0}, \quad T_1^* = \frac{1}{1}, \quad T_{001}^* = \frac{0}{0} 1, \quad T_{001}^* = \frac{0}{0} 1, \quad T_{011}^* = \frac{0}{0} 1 1.
\]

In length 4, appears the first linear combination

\[
T_{0001}^* = \frac{0}{0} 0 0 1, \quad T_{0011}^* = \frac{0}{0} 0 1 1, \quad T_{0101}^* = \frac{0}{0} 1 0 1 + \frac{0}{0} 1 1 0, \quad T_{0111}^* = \frac{0}{0} 1 1 1.
\]

due to the fact that both \( [0] \wedge [011] \) and \( [001] \wedge [1] \) are mapped onto \( [0011] = [X_0, [X_0, X_1, X_1]] \) under the bracket map.

In weight 5, we will concentrate our attention on the two following examples

\[
T_{00101}^* = \frac{0}{0} 0 0 1 0 1, \quad T_{00101}^* = \frac{0}{0} 0 1 0 1 1 + \frac{0}{0} 1 0 1 0 1 + \frac{0}{0} 1 1 0 1 0.
\]

**2.2. Another differential on trees.** In [GGL09], Gangl, Goncharov and Levin introduced a differential \( d_{cy} \) on trees which reflects the differential in Bloch cycle algebra \( \mathcal{N}_{	ext{Spec}(\mathbb{Q})} \) (see Section 3). In their work they have shown that some particular linear combinations of trivalent trees attached to decompositions of polygons have decomposable differential. More precisely, the differential of these particular linear combinations of trees is a linear combination of products of the same type of linear combinations of trees. The elements \( T_{W^*} \) have a similar behavior under \( d_{cy} \).

One begins by endowing trees with an extra structure.

**Definition 2.3.** An orientation \( \omega \) of a tree \( T \) (or a forest) is a numbering of the edges. That is if \( T \) has \( n \) edges and if \( E(T) \) denotes its set of edges, \( \omega \) is a map \( E(T) \rightarrow \{1, \ldots, n\} \).

**Definition 2.4.**

- Let \( V^t \) be the \( \mathbb{Q} \)-vector space generated by a unit 1 and oriented forests of rooted trees \( T \) with root vertex decorated by: \( t, 0 \) or 1 and leaves decorated by 0 or 1.
• Let \( \cdot \) denote the product induced by the disjoint union of the trees and shift of the numbering for the orientation of the second factor. That is the product of \( (F_1, \omega_1) \) and \( F_2, \omega_2 \) is the forest \( F = F_1 \sqcup F_2 \) together with the numbering \( \omega = \omega_1 \) and \( \omega_{F_2} = \omega_2 + n_1 \) where \( n_1 \) is the number of edges in \( F_1 \). Note that here, by convention the empty tree is \( 0 \) and the unit for \( \cdot \) is the extra generator \( 1 \).

• Define \( \mathcal{F}_Q^\bullet \) to be the algebra \( \mathcal{V}^T \) modulo the relations:

\[
(T, \sigma(\omega)) = \varepsilon(\sigma)(T, \omega), \quad \sigma_{12} = 0 \quad \text{and} \quad \sigma_0 = 0.
\]

for any permutation \( \sigma \).

Remark 2.5. (1) There is an obvious direction on the edges of a rooted tree: away from the root.

(2) A rooted tree comes with a canonical numbering, starting from the root edge and induced by the cyclic ordering at each vertex.

Example 2.6. With our convention, an example of this canonical ordering is shown at Figure 1; we recall that by convention we draw trees with the root at the top and the cyclic order at internal vertices counterclockwise.

![Figure 1](image)

Figure 1. A tree with its canonical orientation, that is the canonical numbering of its edge.

Now, we define on \( \mathcal{F}_Q^\bullet \) a differential satisfying \( d^2 = 0 \) and the Leibniz rule

\[
d((F_1, \omega_1) \cdot (F_2, \omega_2)) = d((F_1, \omega_1)) \cdot (F_2, \omega_2) + (-1)^{e(F_1)}(F_1, \omega_1) \cdot d((F_2, \omega_2)).
\]

The set of rooted planar trees decorated as above endowed with their canonical orientation forms a set of representative for the permutation relation and it generates \( \mathcal{F}_Q^\bullet \) as an algebra. Hence, we will define this differential first on these tree and then extend the definition by Leibniz rule.

The differential of an oriented tree \((T, \omega)\) is a linear combination of oriented forests where the trees appearing arise by contracting an edge of \(T\) and fall into two types depending whether the edge is internal or not. We will need the notion of splitting.

Definition 2.7. A splitting of a tree \( T \) at an internal vertex \( v \) is the disjoint union of the trees which arise as \( T_i \cup v \) where the \( T_i \) are the connected component of \( T \setminus v \). Moreover

• the planar structure of \( T \) and its decorations of leaves induce a planar structure on each \( T_i \cup v \) and decorations of leaves;

• an ordering of the edges of \( T \) induces an orientation of the forest \( \sqcup_i (T_i \cup v) \);

• if \( T \) as a root \( r \) then \( v \) becomes the root for all \( T_i \cup v \) which do not contain \( r \), and if \( v \) has a decoration then it keeps its decoration in all the \( T_i \cup v \).

Definition 2.8. Let \( e \) be an edge of a tree \( T \). The contraction of \( T \) along \( e \) denoted \( T/e \) is given as follows:
(1) If the tree consists on a single edge, its contraction is the empty tree.
(2) If $e$ is an internal edge, then $T/e$ is the tree obtained from $T$ by contracting $e$ and identifying the incident vertices to a single vertex.
(3) If $e$ is the edge containing the root vertex then $T/e$ is the forest obtained by first contracting $e$ to the internal incident vertex $w$ (which inherit the decoration of the root) and then by splitting at $w$; $w$ becoming the new root of all trees in the forest $T/e$.
(4) If $e$ is an external edge not containing the root vertex then $T/e$ is the forest obtained as follow: first one contracts $e$ to the internal incident vertex $w$ (which inherit the decoration of the leaf) and then one performs a splitting at $w$.
(5) If $T$ is endowed with its canonical orientation $\omega$ there is a natural orientation $i_\omega$ on $T/e$ given as follows :
\[\forall f \in E(T/e) \quad i_\omega(f) = \omega(f) \quad \text{if} \quad \omega(f) < \omega(e)
\]
\[i_\omega(f) = \omega(f) - 1 \quad \text{if} \quad \omega(f) > \omega(e).
\]

Example 2.9. Two examples are given below. In Figure 2, one contracts the root vertex and in Figure 3, a leaf is contracted.

Definition 2.10. Let $(T,\omega)$ be a tree endowed with its canonical orientation, on defines $d_{cy}(T,\omega)$ as
\[d_{cy}(T,\omega) = \sum_{e \in E(T)} (-1)^{\omega(e)-1}(T/e, i_\omega).
\]
One extends $d_{cy}$ to all oriented trees by the relation $d_{cy}(T, \sigma \circ \omega) = \varepsilon(\sigma)d_{cy}(T, \omega)$ and to $F^*_Q$ by linearity and the Leibniz rule.

In particular $d_{cy}$ maps a tree with at most one edge to 0 (which correspond by convention to the empty tree).

As proved in [GGL09], $d_{cy}$, extended with the Leibniz rule, induces a differential on $F^*_Q$.

Proposition 2.11. The map $d_{cy} : F^*_Q \longrightarrow F^*_Q$ makes $F^*_Q$ into a commutative differential graded algebra. In particular $d_{cy}^2 = 0$.

The main result of the combinatorial aspects is the following.
Theorem 2.12. By an abuse of notation, for any Lyndon word $U$ the image of $T_U$ in $\mathcal{F}_Q^*$ with root vertex decorated by $t$ and canonical orientation is also denoted by $T_U^\ast$. The image of $T_U$ in $\mathcal{F}_Q^*$ with root vertex decorated by $1$ and canonical orientation is denoted by $T_U^\ast(1)$.

Let $W$ be a Lyndon word. Then, the following equality holds in $\mathcal{F}_Q^*$:

$$(\text{ED-T}) \quad d_{cy}(T_W^\ast) = \sum_{U < V} \alpha_{U,V}^W T_U^\ast \cdot T_V^\ast + \sum_{U,V} \beta_{U,V}^W T_U^\ast \cdot T_V^\ast(1)$$

where the $\alpha_{U,V}^W$ are the one from Equation (1).

For a detailed proof, we refer to [Sou12]. The theorem mainly follow by induction from the combinatoric of the free Lie algebra $\text{Lie}(X_0, X_1)$:

- The first terms in the R.H.S of (ED-T), comes from the contraction of the root edge which is nothing but the differential $d_{\text{Lie}}$ dual to bracket of $\text{Lie}(X_0, X_1)$
- Using the inductive definition of $T_W^\ast$ (Equation (1)), one shows by induction that as $d_{\text{Lie}}^2 = 0$, internal edges do not contribute.
- Terms in $T_V^\ast(1)$ arise from leaves decorated by $1$. The fact that terms arising from leaves decorated by $1$ can be regroup as a product $T_U^\ast \cdot T_V^\ast(1)$ is due to a particular decomposition of some specific brackets in terms of the Lyndon basis.

Example 2.13. As said before, the trees are endowed with their canonical numbering. First, trees with only one edge are maps to $0$ so

$$d_{cy}(T_0^\ast) = d_{cy}(\begin{array}{c} t \\ 0 \end{array}) = 0 \quad \text{and} \quad d_{cy}(T_1^\ast) = d_{cy}(\begin{array}{c} t \\ 1 \end{array}) = 0.$$ 

We recall that a tree with root decorated by $0$ is $0$ in $\mathcal{F}_Q^*$. As applying an odd permutation to the numbering change the sign of the tree, using the trivalency of the tree $T_W^\ast$ shows that some trees arising from the computation of $d_{cy}$ are $0$ in $\mathcal{F}_Q^*$ because they contain a symmetric subtree.

Using the fact that the tree $\begin{array}{c} 1 \\ 0 \end{array}$ is $0$ in $\mathcal{F}_Q^*$, one computes in weight 2

$$d_{cy}(T_{01}^\ast) = d_{cy}(\begin{array}{c} t \\ 0 \\ 1 \end{array}) = T_0^\ast \cdot T_1^\ast.$$ 

In weight 3, one has

$$d_{cy}(T_{001}^\ast) = d_{cy}(\begin{array}{c} t \\ 0 \\ 0 \\ 1 \end{array}) = T_0^\ast \cdot T_0^\ast \cdot T_1^\ast \quad \text{and} \quad d_{cy}(T_{110}^\ast) = d_{cy}(\begin{array}{c} t \\ 0 \\ 1 \\ 1 \end{array}) = T_{11}^\ast \cdot T_1^\ast \cdot T_{01}^\ast(1).$$ 

In weight 4, one can easily check that

$$d_{cy}(T_{0001}^\ast) = T_{00}^\ast \cdot T_{00}^\ast \quad \text{and} \quad d_{cy}(T_{0111}^\ast) = T_{01}^\ast \cdot T_{11}^\ast + T_{11}^\ast \cdot T_{01}^\ast(1).$$ 

The example of $T_{0011}^\ast$ is more interesting.
\( (2) \)
\[
d_{cy} \left( \begin{array}{c}
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ }
\end{array} \right) = \begin{array}{c}
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ }
\end{array}
\]
\[
+ \begin{array}{c}
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ }
\end{array}
\]
\[
= T_0 \cdot T_{011} + T_{001} \cdot T_1 + T_1 \cdot T_{001} \cdot (1) + T_{01} \cdot T_{01} \cdot (1)
\]

Here, the term in \( T_{01} \cdot T_{01} \cdot (1) \) is coming form the last edge of the tree:

\[
\begin{array}{c}
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ }
\end{array}
\]

appearing in \( T_{0011} \). Computing \( d_{cy}^2 (T_{0011}) \) (which is 0), the differential \( d_{cy} (T_{01} \cdot T_{01} \cdot (1)) \) cancels with the term in \( T_0 \cdot T_1 \cdot T_{01} \cdot (1) \) arising form \( d_{cy} (T_{01} \cdot T_{011}) \). It can be thought as the propagation of the weight 3 correction term \( T_1 \cdot T_{01} \cdot (1) \) appearing in \( d_{cy} (T_{011}) \).

We give below an example in weight 5, \( d_{cy} (T_{01011}) \): 

\[
\begin{array}{c}
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\
\text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } & \text{ } \\

\end{array}
\]

\[
= T_{01} \cdot T_{011} + T_{001} \cdot T_1 + T_1 \cdot T_{001} \cdot (1) + 2 T_{01} \cdot T_{01} \cdot (1)
\]

where the last term arises from the part of the differential associated to edges \( e \) and \( f \). The above equation can be written as

\[ (4) \quad T_{01011} = T_{01} \cdot T_{011} + T_{001} \cdot T_1 + T_1 \cdot T_{001} \cdot (1) + 2 T_{01} \cdot T_{01} \cdot (1) \]
LOW WEIGHT MULTIPLE ZETA VALUES CYCLES

3. Algebraic cycles

This section begins with the construction of the cycle complex (or cycle algebra) as presented in [Blo86, Blo97, BK94, Lev94]. Then, we give some properties of equidimensional cycles groups over $\mathbb{A}^1$ and build some algebraic cycles corresponding to multiple polylogarithms in one variable.

Here, as in all this paper, the base field is $\mathbb{Q}$ and the various structures have $\mathbb{Q}$ coefficients.

3.1. Construction of the cycle algebra. Let $\square^n$ be the algebraic $n$-cube

$$\square^n = (\mathbb{P}^1 \setminus 1)^n.$$ Insertion morphisms $s_i^n : \square^{n-1} \to \square^n$ are given by the identification

$$\square^{n-1} \simeq \square^{-1} \times \{\varepsilon\} \times \square^{-i}$$

for $\varepsilon = 0, \infty$. A face $F$ of codimension $p$ of $\square^n_k$ is given by the equation $x_k = \varepsilon_k$ for $k \in \{1, \ldots, p\}$ and $x_k \in \{0, \infty\}$ where $x_1, \ldots, x_n$ are the usual affine coordinates on $\mathbb{P}^1$. In particular, codimension 1 faces are given by the images of insertions morphisms.

Now, let $X$ be a smooth irreducible quasi-projective variety over $\mathbb{Q}$.

**Definition 3.1.** Let $p$ and $n$ be non negative integers. Let $Z^p(X, n)$ be the free group generated closed irreducible sub-varieties of $X \times \square^n$ of codimension $p$ which intersect all faces $X \times F$ properly (where $F$ is a face of $\square^n$). That is:

$$\mathbb{Z} \left\langle W \subset X \times \square^n \text{ such that } \begin{cases} W \text{ is smooth, closed and irreducible} \\ \text{codim}_{X \times F}(W \cap X \times F) = p \\
\text{or } W \cap X \times F = \emptyset \end{cases} \right\rangle$$

A sub-variety $W$ of $X \times \square^n$ as above is admissible. The insertions morphisms $s_i^n$ induce a well defined pull-back $s_i^n : Z^p(X, n) \to Z^p(X, n-1)$ and a differential:

$$\partial = \sum_{i=1}^n (-1)^{i-1} (s_i^n - s_i^{n+1}) : Z^p(X, n) \to Z^p(X, n-1).$$

The permutation group $S_n$ act on $\square^n$ by permutation of the factor. This action extends to an action of the semi-direct product $G_n = (\mathbb{Z}/2\mathbb{Z})^n \rtimes S_n$ where each $\mathbb{Z}/2\mathbb{Z}$ acts on $\mathbb{P}^1$ by sending the usual affine coordinates $x$ to $1/x$. The sign representation of $S_n$ extends to a sign representation $G_n \mapsto \{\pm 1\}$. Let $\text{Alt}_{2n} \in \mathbb{Q}[G_n]$ be the corresponding projector.

**Definition 3.2.** Let $p$ and $k$ be integers as above. One defines

$$N_X^k(p) = \text{Alt}_{2p-k}(Z(X, 2p-k) \otimes \mathbb{Q}).$$

We will refer to $k$ as the cohomological degree and to $p$ as the weight.

For our purpose, we will need not only need admissible cycles but cycles in $X \times \square^n$ whose fiber over $X$ are also admissible.

**Definition 3.3** (Equidimensionality). Let $X$ be an irreducible smooth variety

- Let $Z^n_{eq}(X, n)$ denote the free abelian group generated by irreducible closed sub-varieties $Z \subset X \times \square^n$ such that for any faces $F$ of $\square^n$, the intersection $Z \cap X \times F$ is empty or the restriction of $p_1 : X \times \square^n \to X$ to $Z \cap (X \times F) \to X$

  is equidimensional of relative dimension $\text{dim}(F) - p$.

- We say that elements of $Z^n_{eq}(X, n)$ are equidimensional over $X$ with respect any faces or simply equidimensional.
Following the definition of $N^k_X(p)$, let $N^{eq,k}_X(p)$ denote

$$N^{eq,k}_X(p) = \text{Alt} \left( Z^l_p(X, 2p - k) \otimes \mathbb{Q} \right).$$

If $Z$ is an irreducible closed subvariety of $X \times \square^n$ satisfying the above condition, $Z|_{t=x}$ will denote the fiber over the point $x \in X$ of $p_1$ restricted to $Z$ that is $Z \cap (\{x\} \times \square^n)$.

Let $C = \text{Alt}(\sum q_i Z_i)$ be an element in $N^{eq,*}_X$ with the $Z_i$ as above and $q_i$’s in $\mathbb{Q}$. For a point $x \in X$, we will denote by $C|_{t=x}$ the element of $N^*_X$

$$C|_{t=x} = \text{Alt}(\sum q_i Z_i|_{t=x})$$

which is well defined in both $N^*_X$ and $N^*_X$ by definition of the $Z_i$.

**Example 3.4.** Consider the graph of the identity $\mathbb{A}^1 \xrightarrow{1} \mathbb{A}^1$ restricted to $\mathbb{A}^1 \times \mathbb{A}^1 \setminus \{1\}$. Let $\Gamma_0$ be its embedding in $\mathbb{A}^1 \times \square^1$. Then $\Gamma_0$ is of codimension 1 in $\mathbb{A}^1 \times \square^1$ and is admissible as the intersection with the face $x_1 = \infty$ is empty and the intersection with the face $x_1 = 0$ is $\{0\} \times \{0\}$ which is of codimension 1 in $\mathbb{A}^1 \times \{0\}$.

However, $\Gamma_0$ is not equidimensional has

$$\Gamma_0 \cap (\{0\} \times \{0\}) = \{0\} \times \{0\}$$

is not empty as the condition would require.

Applying the projector $\text{Alt}$ gives an element $\overline{t}_0$ in $N^1_{\mathbb{A}^1}(1)$. Using the definition of $\Gamma_0$ as a graph, one obtains a parametric representation (where the projector $\text{Alt}$ is omitted):

$$\overline{t}_0 = [t: \bar{t}] \subset \mathbb{A}^1 \times \square^1.$$  

In the above notation the semicolon separates the base space coordinates from the cubical coordinates

The morphisms $s_i^k$ induce morphisms $\partial_i^k : N^k_X(p) \to N^{k+1}_X(p)$ and the above differential $\partial = \sum_i (-1)^{i-1}(\partial_i^0 - \partial_i^\infty)$ gives a complex

$$N^*_X(p) : \cdots \to N^k_X(p) \xrightarrow{\partial} N^{k+1}_X(p) \to \cdots$$

**Definition 3.5.** One defines the cycle complex as

$$N^*_X = \bigoplus_{p \geq 0} N^k_X(p) = \bigoplus_{p \geq 1} N^{eq,k}_X(p)$$

and as the differential restricts to equidimensional cycles, one also defines

$$N^{eq,*}_X = \bigoplus_{p \geq 0} N^{eq,k}_X(p).$$

The author refer sometimes to $N^*_X$ as the cycle algebra because of another natural structure coming with this cubical cycle complex : the product structure.

Levine has shown in [Lev94][§5] or [Lev11][Example 4.3.2] the following proposition.

**Proposition 3.6.** Concatenation of the cube factors and pull-back by the diagonal

$$X \times \square^n \times X \times \square^m \xrightarrow{\Delta_X} X \times X \times \square^n \times \square^m \xrightarrow{\Delta_X} X \times X \times \square^{n+m}$$

induced, after applying the $\text{Alt}$ projector, a well-defined product:

$$N^k_X(p) \otimes N^l_X(q) \to N^{k+l}_X(p + q)$$

denoted by $\cdot$.

The complex $N^{eq,*}_X$ is stable under this product law.

**Remark 3.7.** The smoothness hypothesis on $X$ allows us to consider the pull-back by the diagonal $\Delta_X : X \to X \times X$ which is in this case of local complete intersection.
One has the following theorem (also stated in [BK94] [Bl597] for \(X = \text{Spec}(K)\)).

**Theorem 3.8 ([Lev94]).** The cycle complex \(N^*_X\) is an Adams graded differential graded commutative algebra. In weight \(p\), its cohomology groups are the higher Chow group of \(X\):

\[ H^k(N^*_X(p)) = CH^p(X, 2p - k)_\mathbb{Q}, \]

where \(CH^p(X, 2p - k)_\mathbb{Q}\) stands for \(CH^p(X, 2p - k) \otimes \mathbb{Q}\).

Moreover \(N^*_X\) turns into a sub-Adams graded differential commutative graded-algebra.

One has natural flat pull-back and proper push-forward on \(N^*_X\) (and on \(N^*_X\)). Comparison with Higher Chow groups also gives on the cohomology groups both \(\mathbb{A}^1\)-homotopy invariance and the long exact sequence associated to an open and its closed complement. Writing \(\mathbb{P}^1 \setminus \{0, 1, \infty\}\) as \(\mathbb{A}^1 \setminus \{0, 1\}\) one obtains the following description of \(H^*(N^*_X)(p)\):

\[ H^k(N^*_X(0, 1, \infty)) \cong H^k(N^*_X) \oplus H^{k-1}(N^*_X) \otimes \mathbb{Q}L_0 \oplus H^{k-1}(N^*_X) \otimes \mathbb{Q}L_1, \]

where \(L_0\) and \(L_1\) are in cohomological degree 1 and weight 1 (that is of codimension 1). Their explicit description will be given later on.

Comparing situation over \(\mathbb{P}^1 \setminus \{0, 1, \infty\}\) and over \(\mathbb{A}^1\) comes as an important idea in our project as the desired cycles over \(\mathbb{P}^1 \setminus \{0, 1, \infty\}\) need to admit a natural specialization at 1. In particular, we will need to work with equidimensional cycles and some of their properties are given in the next subsection.

### 3.2. Equidimensional cycles.

The following result given in [Sou12] essentially follows from the definition and makes it easy to compare both situation.

**Proposition 3.9.** Let \(X_0\) be an open dense subset of \(X\) an irreducible smooth variety and let \(j : X_0 \rightarrow X\) the inclusion. Then the restriction of cycles from \(X\) to \(X_0\) induces a morphism of cdga

\[ j^* : N^*_X \rightarrow N^*_X. \]

Moreover, Let \(C\) be in \(N^*_X\) and be decomposed in terms of cycles as

\[ C = \sum_{i \in I} q_i Z_i, \quad q_i \in \mathbb{Q} \]

where \(I\) is a finite set. Assume that for any \(i\), the Zariski closure \(\overline{Z_i}\) of \(Z_i\) in \(X \times \mathbb{A}^n\) intersected with any face \(F\) of \(\mathbb{A}^n\) is equidimensional over \(X\) of relative dimension \(\dim(F) - p_i\). Define \(C'\) as

\[ C' = \sum_{i \in I} q_i \overline{Z_i}, \]

then,

\[ C' \in N^*_X \quad \text{and} \quad C = j^*(C') \in N^*_X. \]

Below, we describe the main geometric fact that allows the construction of our cycles: pulling back by the multiplication induces an homotopy between identity and the zero section on the cycle algebra over \(\mathbb{A}^1\).

**Proposition 3.10 (multiplication and equimensionality).** Let \(m : \mathbb{A}^1 \times \mathbb{A}^1 \rightarrow \mathbb{A}^1\) be the multiplication map sending \((x, y)\) to \(xy\) and let \(\tau : \mathbb{A}^1 \rightarrow \mathbb{A}^1\) be the isomorphism sending the affine coordinates \(u\) to \(\frac{1}{u}\). The map \(\tau\) sends \(\infty\) to 0, 0 to 1 and extends as a map from \(\mathbb{P}^1\) to \(\mathbb{P}^1\) sending 1 to \(\infty\).

Maps \(m\) and \(\tau\) are in particular flat and equidimensional of relative dimension 1 and 0 respectively.
Consider the following commutative diagram for a positive integer $n$

$$
\begin{array}{c}
\mathbb{A}^1 \times \square^1 \times \square^n \\
p_{\mathbb{A}^1 \times \square^1} \\
\mathbb{A}^1 \times \square^1
\end{array} \xrightarrow{(m \circ (id_{\mathbb{A}^1} \times \tau)) \times id_{\square^n}} \begin{array}{c}
\mathbb{A}^1 \times \square^n \\
p_{\mathbb{A}^1} \\
\mathbb{A}^1
\end{array}
$$

In the following statement, $p$, $k$ and $n$ will denote positive integers subject to the relation $n = 2p - k$.

- the composition $\tilde{m} = (m \circ (id_{\mathbb{A}^1} \times \tau)) \times id_{\square^n}$ induces a group morphism
  $$Z^p_\text{eq}(\mathbb{A}^1, n) \xrightarrow{\tilde{m}^*} Z^p_\text{eq}(\mathbb{A}^1 \times \square^1, n)$$
  which extends into a morphism of complexes for any $p$
  $$N_{\mathbb{A}^1}^{\text{eq}, \bullet} (p) \xrightarrow{\tilde{m}^*} N_{\mathbb{A}^1 \times \square^1}^{\text{eq}, \bullet} (p).$$
- Moreover, one has a natural morphism
  $$h^p_{\mathbb{A}^1, n} : Z^p_\text{eq}(\mathbb{A}^1 \times \square^1, n) \longrightarrow Z^p_\text{eq}(\mathbb{A}^1, n + 1)$$
given by regrouping the $\square$'s factors.
- The composition $\mu^* = h^p_{\mathbb{A}^1, n} \circ \tilde{m}^*$ gives a morphism
  $$\mu^* : N_{\mathbb{A}^1}^{\text{eq}, k} (p) \longrightarrow N_{\mathbb{A}^1}^{\text{eq}, k-1} (p)$$
sending equidimensional cycles with empty fiber at 0 to equidimensional cycles with empty fiber at 0.
- Let $\theta : \mathbb{A}^1 \longrightarrow \mathbb{A}^1$ be the involution sending the natural affine coordinate $t$ to $1 - t$. Twisting the multiplication $\tilde{m}$ by $\theta$ via

$$
\begin{array}{c}
\mathbb{A}^1 \times \square^1 \times \square^n \\
\theta \times id_{\square^n+1} \\
\mathbb{A}^1 \times \square^1 \times \square^n \\
\theta \times id_{\square^n}
\end{array} \xrightarrow{\tilde{m}} \begin{array}{c}
\mathbb{A}^1 \times \square^n \\
\mathbb{A}^1 \times \square^1 \times \square^n
\end{array}
$$

gives a morphism

$$
\nu^* : N_{\mathbb{A}^1}^{\text{eq}, k} (p) \longrightarrow N_{\mathbb{A}^1}^{\text{eq}, k-1} (p)
$$
sending equidimensional cycles with empty fiber at 1 to equidimensional cycles with empty fiber at 1.

**Proof.** It is enough to work with generators of $Z^p_\text{eq}(\mathbb{A}^1, n)$. Let $Z$ be an irreducible subvariety of $\mathbb{A}^1 \times \square^n$ such that for any faces $F$ of $\square^n$, the first projection

$$p_{\mathbb{A}^1} : Z \cap (\mathbb{A}^1 \times F) \longrightarrow \mathbb{A}^1$$

is equidimensional of relative dimension $\dim(F) - p$ or empty. Let $F$ be a face of $\square^n$. First, We want to show that under the projection $\mathbb{A}^1 \times \square^1 \times \square^n \longrightarrow \mathbb{A}^1 \times \square^1$,

$$\tilde{m}^{-1}(Z) \cap (\mathbb{A}^1 \times \square^1 \times F) \longrightarrow \mathbb{A}^1 \times \square^1$$

is equidimensional of relative dimension $\dim(F) - p$ or empty. This follows from the fact that $Z \cap (\mathbb{A}^1 \times F)$ is equidimensional over $\mathbb{A}^1$ and $\tilde{m}$ is flat and equidimensional of relative dimension 1 (hence are $m \times \tau$ and $\tilde{m}$). The map $\tilde{m}$ is identity on the $\square^n$. 
factor, thus for $Z \subset \mathbb{A}^1 \times \square^n$ as above and a codimension 1 face $F$ of $\square^n$, $\tilde{m}^{-1}(Z)$ satisfies

$$\tilde{m}^{-1}(Z) \cap (\mathbb{A}^1 \times \square^1 \times F) = \tilde{m}^{-1}(Z \cap (\mathbb{A}^1 \times F))$$

which makes $\tilde{m}^*$ into a morphism of complex.

Moreover, assuming that the fiber of $Z$ at 0 is empty, as $\tilde{m}$ restricted to $
\{0\} \times \square^1 \times \square^n$
factors through the inclusion $\{0\} \times \square^n \rightarrow \mathbb{A}^1 \times \square^n$, the intersection

$$\tilde{m}^{-1}(Z) \cap (\{0\} \times \square^1 \times \square^n)$$
is empty. Hence the fiber of $\tilde{m}^{-1}(Z)$ over $\{0\} \times \square^1$ by $p_{\mathbb{A}^1 \times \square}$ is empty and the same holds for the fiber over $\{0\}$ by $p_{\mathbb{A}^1 \times \square}$.

Now, let $Z$ be an irreducible subvariety of $\mathbb{A}^1 \times \square^1 \times \square^n$ such that for any face $F$ of $\square^n$

$$Z \cap (\mathbb{A}^1 \times \square^1 \times F) \rightarrow \mathbb{A}^1 \times \square^1$$
is equidimensional of relative dimension $\dim(F) - p$. Let $F'$ be a face of

$$\square^{n+1} = \square^1 \times \square^n.$$
The face $F'$ is either of the form $\square^1 \times F$ or of the form $\{\varepsilon\} \times F$ with $F$ a face of $\square^n$ and $\varepsilon \in \{0, \infty\}$. If $F'$ is of the first type, as

$$Z \cap (\mathbb{A}^1 \times \square^1 \times F) \rightarrow \mathbb{A}^1 \times \square^1$$
is equidimensional and as $\mathbb{A}^1 \times \square^1 \rightarrow \mathbb{A}^1$ is equidimensional of relative dimension 1, the projection

$$Z \cap (\mathbb{A}^1 \times \square^1 \times F) \rightarrow \mathbb{A}^1$$
is equidimensional of relative dimension

$$\dim(F) - p + 1 = \dim(F') - p.$$

If $F'$ is of the second type, by symmetry of the role of 0 and $\infty$, we can assume that $\varepsilon = 0$. Then, the intersection

$$Z \cap (\mathbb{A}^1 \times \{0\} \times F)$$
is nothing but the fiber of $Z \cap (\mathbb{A}^1 \times \square^1 \times F)$ over $\mathbb{A}^1 \times \{0\}$. Hence, it has pure dimension

$$\dim(F) - p + 1.$$

Moreover, denoting with a subscript the fiber, the composition

$$Z \cap (\mathbb{A}^1 \times \{0\} \times F) = (Z \cap (\mathbb{A}^1 \times \square^1 \times F))|_{\mathbb{A}^1 \times \{0\}} \rightarrow \mathbb{A}^1 \times \{0\} \rightarrow \mathbb{A}^1$$
is equidimensional of relative dimension

$$\dim(F) - p = \dim(F') - p.$$

This shows that $h_{\mathbb{A}^1,n}^P$ gives a well define morphism and that it preserves the fiber at a point $x$ in $\mathbb{A}^1$; in particular if $Z$ has an empty fiber at 0, so does $h_{\mathbb{A}^1,n}^P(Z)$.

Finally, the last part of the proposition is deduced from the fact that $\theta$ exchanges the role of 0 and 1.

Remark 3.11. We have remarked that $\tilde{m}$ sends cycles with empty fiber at 0 to cycles with empty fiber at any point in $\{0\} \times \square^1$. Similarly $\tilde{m}$ sends cycles with empty fiber at 0 to cycles that also have an empty fiber at any point in $\mathbb{A}^1 \times \{\infty\}$.

From the proof of Levine’s Proposition 4.2 in [Lev94], we deduce that $\mu^*$ gives a homotopy between $p_0 \circ i_0^*$ and id where $i_0$ is the zero section $\{0\} \rightarrow \mathbb{A}^1$ and $p_0$ the projection onto the point $\{0\}$.
Proposition 3.12. Notations are the ones from Proposition 3.10 above. Let \( i_0 \) (resp. \( i_1 \)) be the inclusion of \( 0 \) (resp. \( 1 \)) in \( A^1 \):
\[
i_0: \{0\} \rightarrow A^1 \quad \text{and} \quad i_1: \{1\} \rightarrow A^1.
\]
Let \( p_0 \) and \( p_1 \) be the corresponding projections \( p_\varepsilon: A^1 \rightarrow \{\varepsilon\} \) for \( \varepsilon = 0, 1 \).

Then, \( \mu^* \) provides a homotopy between
\[
p_0^* \circ i_0^* \text{ and } id : \mathcal{N}_{A^1}^{eq} \rightarrow \mathcal{N}_{A^1}^{eq}.
\]
and similarly \( \nu^* \) provides a homotopy between
\[
p_1^* \circ i_1^* \text{ and } id : \mathcal{N}_{A^1}^{eq} \rightarrow \mathcal{N}_{A^1}^{eq}.
\]
In other words, one has
\[
\partial(h_1^0 + \mu^* \circ \partial) = -p_0^* \circ i_0^* \quad \text{and} \quad \partial(h_1^1 + \nu^* \circ \partial) = -p_1^* \circ i_1^*.
\]

The proposition follows from computing the different compositions involved and the relation between the differential on \( \mathcal{N}_{A^1}^{eq} \times \square^1 \) and the one on \( \mathcal{N}_{A^1}^{eq} \) via the map \( h_{A^1,n}^n \).

Proof. We denote by \( i_0, \square \) and \( i_\infty, \square \) the zero section and the infinity section \( A^1 \rightarrow A^1 \times \square^1 \). The action of \( \theta \) only exchanges the role of \( 0 \) and \( 1 \) in \( A^1 \), hence it is enough to prove the statement for \( \mu^* \). As previously, in order to obtain the proposition for \( \mathcal{N}_{A^1}^{eq,k}(p) \), it is enough to work on the generators of \( Z_{eq}^p(A^1, n) \) with \( n = 2p + k \).

By the previous proposition 3.10, \( \tilde{m}^* \) commutes with the differential on \( Z_{eq}^p(A^1, \bullet) \) and on \( Z_{eq}^p(A^1 \times \square^1, \bullet) \). As the morphism \( \mu^* \) is defined by \( \mu^* = h_{A^1,n}^n \circ \tilde{m}^* \), the proof relies on computing \( \partial(h_1^0 \circ h_{A^1,n}^n) \). Let \( Z \) be a generator of \( Z_{eq}^p(A^1 \times \square^1, n) \). In particular,
\[
Z \subseteq A^1 \times \square^1 \times \square^n
\]
and \( h_{A^1,n}^n(Z) \) is also given by \( Z \) but viewed in
\[
A^1 \times \square^{n+1}.
\]
The differentials denoted by \( \partial_{h_{A^1,n}^n}^{n+1} \) on \( Z_{eq}^p(A^1, n+1) \) and \( \partial_{A^1 \times \square^n} \) on \( Z_{eq}^p(A^1 \times \square^1, n) \) are both given by intersections with the codimension 1 faces but the first \( \square^1 \) factor in \( \square^{n+1} \) gives two more faces and introduces a change of sign. Namely, using an extra subscript to indicate in which cycle groups the intersections take place, one has:
\[
\partial_{h_{A^1,n}^n}^{n+1}(h_{A^1,n}^n(Z)) = \sum_{i=1}^{n+1} (-1)^{i-1} \left( \partial_{i,A^1}^0(Z) - \partial_{i,A^1}^\infty(Z) \right)
\]
\[
= \partial_{i,A^1}^0(Z) - \partial_{i,A^1}^\infty(Z) - \sum_{i=2}^{n+1} (-1)^{i-2} \left( \partial_{i-1,A^1}^0(Z) - \partial_{i-1,A^1}^\infty(Z) \right)
\]
\[
= i_{0,\square}^0(Z) - i_{\infty,\square}^\infty(Z) - \sum_{i=1}^{n} (-1)^{i-1} \left( \partial_{i+1,A^1}^0(Z) - \partial_{i+1,A^1}^\infty(Z) \right)
\]
\[
= i_{0,\square}^0(Z) - i_{\infty,\square}^\infty(Z) - \sum_{i=1}^{n} (-1)^{i-1} \left( h_{A^1,n-1}^0 \circ \partial_{i,A^1 \times \square^1}^0(Z) - h_{A^1,n-1}^\infty \circ \partial_{i,A^1 \times \square^1}^\infty(Z) \right)
\]
\[
= i_{0,\square}^0(Z) - i_{\infty,\square}^\infty(Z) - h_{A^1,n-1}^0 \circ \partial_{0,A^1 \times \square^1}^0(Z).
\]
Thus, one can compute $\partial_{A^1} \circ \mu^* + \mu^* \circ \partial_{A^1}$ on $\mathbb{Z}_p^n(A^1, n)$ as
\[ \partial_{A^1} \circ \mu^* + \mu^* \circ \partial_{A^1} = \partial_{A^1} \circ \mu_{A^1,n} \circ \tilde{m}^* + h_{A^1,n-1} \circ \partial_{A^1} \circ \tilde{m}^* \]
\[ = i_{A^1}^* \circ \tilde{m}^* - i_{\infty}^* \circ \tilde{m}^* - h_{A^1,n-1} \circ \partial_{A^1} \circ \tilde{m}^* + h_{A^1,n-1} \circ \partial_{A^1} \circ \tilde{m}^*. \]

The morphism $i_{\infty}^* \circ \tilde{m}^*$ is induced by
\[ A^1 \xrightarrow{i_{\infty}^*} A^1 \times \{1\} \xrightarrow{r} A^1 \times A^1 \xrightarrow{m} \mathbb{A}^1 \]
which factors through
\[ \xymatrix{ A^1 \ar[r]^{i_{\infty}^*} \ar[d]^{p_0} & A^1 \times \{1\} \ar[r]^{r} \ar[d]^{i_0} & A^1 \times A^1 \ar[r]^{m} \ar[d]^{\text{id}_{A^1}} & \mathbb{A}^1 \ar[d]^{} } \]
Thus,
\[ i_{\infty}^* \circ \tilde{m}^* = (i_0 \circ p_0)^* = p_0^* \circ i_0^*. \]

Similarly $i_{0}^* \circ \tilde{m}^*$ is induced by
\[ A^1 \xrightarrow{i_{0}^*} A^1 \times \{1\} \xrightarrow{r} A^1 \times A^1 \xrightarrow{m} A^1 \]
which factors through $\text{id}_{A^1} : A^1 \to A^1$ and one has
\[ i_{0}^* \circ \tilde{m}^* = \text{id}. \]

which concludes the proof of the proposition. \qed

3.3. Weight 1, weight 2 and polylogarithm cycles. For now on, we set $X = \mathbb{P}^1 \setminus \{0, 1, \infty\}$.

3.3.1. Two weight 1 cycles generating the $H^1$. As said before, there is a decomposition of $H^1(\mathbb{A}^1 \times \{p\})$ as
\[ H^1(\mathbb{A}^1) \cong H^1(\mathbb{A}^1) \oplus H^0(\mathbb{A}^1) \otimes \mathbb{Q}L_0 \oplus H^0(\mathbb{A}^1) \otimes \mathbb{Q}L_1 \]
and $L_0$ and $L_1$ (which are in weight 1 and degree 1) generates the $H^1(\mathbb{A}^1)$ relatively to $H^1(\mathbb{A}^1)$. Explicit expression for $L_0$ and $L_1$ are given below.

At example 3.3, a cycle $L_0$ was constructed using the graph of $t \mapsto t$ from $A^1 \to A^1$. Taking its restriction to $X \times \{1\}$, and using the same convention, one gets a cycle
\[ L_0 = [t; t] \subset X \times \{1\}, \quad L_0 \in \mathcal{N}^1_X(1). \]

Similarly, using the graph of $t \mapsto 1 - t$, one gets
\[ L_1 = [t; 1 - t] \subset X \times \{1\}, \quad L_1 \in \mathcal{N}^1_X(1). \]

Remark that the cycles $L_0$ and $L_1$ are both equidimensional over $X = \mathbb{P}^1 \setminus \{0, 1, \infty\}$ but not equidimensional over $A^1$.

Moreover as
\[ L_0 \cap X \times \{0\} = L_0 \cap \mathbb{P}^1 \setminus \{0, 1, \infty\} \times \{0\} = \emptyset \]
for $\varepsilon = 0, \infty$, the above intersection tells us that $\partial(L_0) = 0$. Similarly, one shows that $\partial(L_1) = 0$. Thus, $L_0$ and $L_1$ give well defined class in $H^1(\mathbb{A}^1(1))$. 

In order to show that they are non trivial and give the above decomposition of the $H^1(\mathcal{N}_\lambda^1)$, one shows that, in the localization sequence, their images by the boundary map

$$H^1(\mathcal{N}_\lambda^1(1)) \xrightarrow{\delta} H^0(\mathcal{N}_0(0)) \oplus H^0(\mathcal{N}_1(0))$$

are non-zero. It is enough to treat the case of $\mathcal{L}_0$. Recall that $\overline{\mathcal{L}_0}$ is the closure of $\mathcal{L}_0$ in $\mathbb{A}^1 \times \square^1$ and is given by the parametrized cycle

$$\overline{\mathcal{L}_0} = [t; \ell] \subset \mathbb{A}^1 \times \square^1.$$ 

Its intersection with the face $u_1 = 0$ is of codimension 1 in $\mathbb{A}^1 \times \{0\}$ and the intersection with $u_1 = \infty$ is empty. Hence $\overline{\mathcal{L}_0}$ is admissible.

Thus, considering the definition of $\delta$, $\delta(\mathcal{L}_0)$ is given by the intersection of the differential of $\overline{\mathcal{L}_0}$ with $\{0\}$ and $\{1\}$ on respectively, the first and second factor. The above discussion on the admissibility of $\overline{\mathcal{L}_0}$ tells us that $\delta(\mathcal{L}_0)$ is non-zero on the factor $H^0(\mathcal{N}_0(0))$ and 0 on the other factor as the admissibility condition is trivial for $\mathcal{N}_0(0)$ and the restriction of $\overline{\mathcal{L}_0}$ to 1 is empty. The situation is reverse for $\mathcal{L}_1$ using its closure $\overline{\mathcal{L}_1}$ in $\mathbb{A}^1 \times \square^1$.

Hence, if the differential of $\mathcal{L}_0$ and $\mathcal{L}_1$ are 0 in $\mathcal{N}_\lambda^1$, their differentials are no zero in $\mathcal{N}_\lambda^1$ and have a particular behavior when multiply by an equidimensional cycle (see Lemma 3.13 below and Equation (10) for an example). We consider here only equidimensional cycles as it is needed to work with such cycles in order to pull-back by the multiplication. We use below notations of propositions 3.10 and 3.12.

**Lemma 3.13.** Let $C$ be an element in $\mathcal{N}_\lambda^1\bullet$, then

$$\partial_{\mathcal{A}^1}(\overline{\mathcal{L}_0}) C = C|_{t=0} \quad \text{and} \quad \partial_{\mathcal{A}^1}(\overline{\mathcal{L}_1}) C = C|_{t=1}$$

where the notation $C|_{t=0}$ (resp. $C|_{t=1}$) denotes, as in Definition 2.2, the (image under the projector $\mathcal{A}t$ of the) fiber at 0 (resp. 1) of the irreducible closed subvarieties composing the formal sum that defines $C$.

**Proof.** It is enough to assume that $C$ is given by $C = \mathcal{A}t(Z)$ where $Z$ is an irreducible closed subvarieties of $\mathbb{A}^1 \times \square^n$ such that for any faces $F$ of $\square^n$, the intersection $Z \cap X \times F$ is empty or the restriction of $p_1 : \mathbb{A}^1 \times \square^n \to \mathbb{A}^1$ to $Z \cap (\mathbb{A}^1 \times F) \to \mathbb{A}^1$

is equidimensional of relative dimension $\dim(F) - p$.

Remark that for $\varepsilon = 0, 1$ the cycle $\partial_{\mathcal{A}^1}(\overline{\mathcal{L}_\varepsilon})$ is given by the point

$$\{\varepsilon\} \in \mathbb{A}^1$$

which is of codimension 1 in $\mathbb{A}^1$. In order to compute the product $\partial_{\mathcal{A}^1}(\overline{\mathcal{L}_\varepsilon}) C$, one considers first the product in $\mathbb{A}^1 \times \mathbb{A}^1 \times \square^n$:

$$\{\varepsilon\} \times Z \subset \mathbb{A}^1 \times \mathbb{A}^1 \times \square^n.$$ 

Let $\Delta$ denotes the image of the diagonal $\mathbb{A}^1 \to \mathbb{A}^1 \times \mathbb{A}^1$. The equidimensionality of $Z$ insures that for any face $F$ of $\square^n$

$$((\varepsilon) \times Z) \cap (\Delta \times F) \simeq (Z \cap (\varepsilon) \times \square^n) \cap (\mathbb{A}^1 \times F)$$

is of codimension $p + 1$. Thus the product $\partial_{\mathcal{A}^1}(\overline{\mathcal{L}_\varepsilon}) C$ is simply the image by $\mathcal{A}t$ of

$$(Z \cap (\varepsilon) \times \square^n) = Z|_{t=\varepsilon} \subset \mathbb{A}^1 \times \square^n.$$

$\square$
3.3.2. A weight 2 example: the Totaro cycle. One considers the linear combination
\[ b = \mathcal{L}_0 \cdot \mathcal{L}_1 \in \mathcal{N}_\mathbb{A}^1(2). \]
It is given as a parametrized cycle by
\[ b = [t; t, 1 - t] \subset X \times \square^2 \]
or in terms of defining equations by
\[ T_1V_1 - U_1T_2 = 0 \quad \text{and} \quad U_1V_2 + U_2V_1 = V_1V_2 \]
where \( T_i \) and \( T_2 \) denote the homogeneous coordinates on \( X = \mathbb{P}^1 \setminus \{0, 1, \infty\} \) and \( U_i, V_i \) the homogeneous coordinates on each factor \( \square^1 = \mathbb{P}^1 \setminus \{1\} \) of \( \square^2 \). One sees that the intersection of \( b \) with faces \( U_i \) or \( V_i \) for \( i = 1, 2 \) is empty because \( T_1 \) and \( T_2 \) are different from 0 in \( X \) and because \( U_i \) is different from \( V_i \) in \( \square^1 \). Thus it tells us that
\[ \partial(b) = 0. \]

Now, let \( \overline{b} \) denote the algebraic closure of \( b \) in \( \mathbb{A}^1 \times \square^2 \). As previously, its expression as parametrized cycle is
\[ \overline{b} = \mathcal{L}_0 \mathcal{L}_1 = [t; t, 1 - t] \subset \mathbb{A}^1 \times \square^2 \]
and the intersection with \( \mathbb{A}^1 \times F \) for any codimension 1 face \( F \) of \( \square^2 \) is empty. Writing, as before, \( \partial_{\mathbb{A}^1} \) the differential in \( \mathcal{N}_{\mathbb{A}^1} \), one has \( \partial_{\mathbb{A}^1}(\overline{b}) = 0 \).

As \( \mathcal{L}_{00} \) (resp. \( \mathcal{L}_1 \)) is equidimensional over \( \mathbb{A}^1 \setminus \{0\} \) (resp. over \( \mathbb{A}^1 \setminus \{1\} \)), the cycle \( \overline{b} \) is equidimensional over \( \mathbb{A}^1 \setminus \{0, 1\} \). Moreover, as \( \mathcal{L}_{00} \) (resp. \( \mathcal{L}_1 \)) has an empty fiber at 1 (resp. at 0), \( \overline{b} \) has empty fiber at both 0 and 1. So \( \overline{b} \) is equidimensional over \( \mathbb{A}^1 \) with empty fibers at 0 and 1. Following notations of Proposition 3.12 one defines two elements in \( \mathcal{N}_{\mathbb{A}^1}^2(2) \) and by pull back by the multiplication (resp. twisted multiplication):
\[ \mathcal{L}_{01} = \mu^*(\overline{b}) \quad \text{and} \quad \mathcal{L}_{01}^1 = \nu^*(\overline{b}). \]

One also defines their restriction to \( X \)
\[ \mathcal{L}_{01} = j^*(\mathcal{L}_{01}^1) \quad \text{and} \quad \mathcal{L}_{01}^1 = j^*(\mathcal{L}_{01}). \]

Now, direct application of Proposition 3.12 shows that
\[ \partial_{\mathbb{A}^1}(\mathcal{L}_{01}) = -\mu^*(\partial_{\mathbb{A}^1}(\overline{b})) + \overline{b} - p_0^0 \circ i_0^0(b) = -\mathcal{L}_0 \mathcal{L}_1 = 0 \]
because \( \overline{b} \) has empty fiber at 0 and is 0 under \( \partial_{\mathbb{A}^1} \). More generally, as \( j^* \) is a morphism of c.d.g.a, Proposition 3.12 gives the following.

Lemma 3.14. Cycles \( \mathcal{L}_{01}, \mathcal{L}_0^1, \mathcal{L}_{01}^1 \) and \( \mathcal{L}_{01}^1 \) satisfy the following properties

1. \( \mathcal{L}_{01} \) and \( \mathcal{L}_{01}^1 \) (resp. \( \mathcal{L}_0^1 \) and \( \mathcal{L}_{01}^1 \)) are equidimensional over \( X \), that is elements in \( \mathcal{N}_{\mathbb{A}^1}^{eq,1}(2) \) (resp. over \( \mathbb{A}^1 \), that is elements in \( \mathcal{N}_{\mathbb{A}^1}^{eq,1}(2) \)).

2. They satisfy the following differential equations
\[ \partial(\mathcal{L}_{01}) = \partial(\mathcal{L}_{01}^1) = b = \mathcal{L}_0 \mathcal{L}_1 \]
and \( \partial_{\mathbb{A}^1}(\mathcal{L}_{01}) = \partial_{\mathbb{A}^1}(\mathcal{L}_{01}^1) = \overline{b} = \mathcal{L}_0 \mathcal{L}_1 \).

3. By the definition given at Equation (8), the cycle \( \mathcal{L}_{01} \) (resp. \( \mathcal{L}_{01}^1 \)) extends \( \mathcal{L}_{01} \) (resp. \( \mathcal{L}_{01}^1 \)) over \( \mathbb{A}^1 \) and has an empty fiber at 0 (resp. at 1).

Moreover, one can explicitly compute the two pull-backs and obtain parametric representations
\[ \mathcal{L}_{01} = [t; t - \frac{t}{x}, x, 1 - x], \quad \mathcal{L}_{01}^1 = [t; \frac{x - t}{x - 1}, x, 1 - x]. \]
The multiplication map inducing \( \mu^* \) is given by
\[ \mathbb{A}^1 \times \Box^1 \times \Box^2 \to \mathbb{A}^1 \times \Box^2, \quad [t; u_1, u_2, u_3] \mapsto \left[ \frac{t}{1-u}; u_2, u_3 \right]. \]

In order to compute the pull-back, one should remark that if \( u = 1 - t/x \) then
\[
\frac{t}{1-u} = x.
\]
Computing the pull-back by \( \mu^* \), is then just rescaling the new \( \Box^1 \) factor which arrives in first position. The case of \( \nu^* \) is similar but using the fact that for \( u = \frac{t}{t-x} \) one has
\[
\frac{t-u}{1-u} = x.
\]

**Remark 3.15.** The cycle \( \mathcal{L}_{01} \) is nothing but Totaro’s cycle \([\text{Tot92}]\), already described in \([\text{BK94}, \text{Blo91}]\).

Moreover, \( \mathcal{L}_{01} \) corresponds to the function \( t \mapsto \mathcal{L}_{01}^y(t) \) as shown in \([\text{BK94}]\).

One recovers the value \( \zeta(2) \) by specializing at \( t = 1 \) using the extension of \( \mathcal{L}_{01} \) to \( \mathbb{A}^1 \).

### 3.3.3. Polylogarithms cycles.

By induction, one can build cycle \( \text{Li}_{2^n}^y = \mathcal{L}_{0-01} \) \( (n-1) \) zeros and one \( 1 \). We define \( \text{Li}_1^y \) to be equal to \( \mathcal{L}_1 \).

**Lemma 3.16.** For any integer \( n \geq 2 \) there exists equidimensional cycles over \( X \), \( \text{Li}_{2^n}^y \) in \( \mathcal{N}_X^{\epsilon_2,n}(n) \subset \mathcal{N}_X^{\epsilon_1,n}(n) \) satisfying

1. There exist equidimensional cycles over \( \mathbb{A}^1 \), \( \overline{\text{Li}_{n}^y} \) in \( \mathcal{N}_n^{\epsilon_1,n}(n) \), such that \( \text{Li}_{2^n}^y = j^*(\overline{\text{Li}_{n}^y}) \) (its has in particular a well defined fiber at \( 1 \)).
2. The cycle \( \overline{\text{Li}_{n}^y} \) has empty fiber at \( 0 \).
3. Cycles \( \text{Li}_{2^n}^y \) and \( \overline{\text{Li}_{n}^y} \) satisfy the differential equations
   \[
   \partial(\text{Li}_{2^n}^y) = \mathcal{L}_0 \cdot \text{Li}_{n-1}^y \quad \text{and} \quad \partial(\overline{\text{Li}_{n}^y}) = \mathcal{L}_0 \cdot \overline{\text{Li}_{n-1}^y}.
   \]
4. \( \text{Li}_{2^n}^y \) is explicitly given as a parametrized cycle by
   \[
   [t; 1 - \frac{t}{x_{n-1}}, x_{n-1}, 1 - \frac{x_{n-1}}{x_{n-2}}, x_{n-2}, \ldots, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1] \subset X \times \Box^{2n-1}.
   \]

**Proof.** For \( n = 2 \), we have already defined \( \text{Li}_2^y = \mathcal{L}_{01} \) satisfying the expected properties.

Assume that one has built the cycles \( \text{Li}_{2^k}^y \) for \( 2 \leq k < n \). One considers in \( \mathcal{N}_n^{\epsilon_2}(n) \) the product
\[
\overline{\mathcal{L}_0} = \mathcal{L}_0 \cdot \text{Li}_{n-1}^y = [t; t, 1 - \frac{t}{x_{n-2}}, x_{n-2}, 1 - \frac{x_{n-2}}{x_{n-3}}, x_{n-3}, \ldots, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1].
\]
As \( \overline{\mathcal{L}_0} \) is equidimensional over \( \mathbb{A}^1 \setminus \{0\} \) and as \( \text{Li}_{n-1}^y \) is equidimensional over \( \mathbb{A}^1 \), \( \overline{\mathcal{L}_0} \) is equidimensional over \( \mathbb{A}^1 \setminus \{0\} \). Moreover, as \( \text{Li}_{n-1}^y \) has empty fiber at \( 0 \), \( \overline{\mathcal{L}_0} \) is equidimensional over \( \mathbb{A}^1 \) with empty fiber at \( 0 \).

Computing the differential with the Leibniz rule and Lemma 3.13 one gets
\[
\partial_{\mathbb{A}^1} \overline{\mathcal{L}_0} = \text{Li}_{n-2}^y \big|_{t=0} = \mathcal{L}_0 \cdot \text{Li}_{n-2}^y = 0.
\]

One concludes using Proposition 3.12. The same argument used to obtain the parametrized representation for \( \mathcal{L}_{01} \) at Equation (7) shows that
\[
\text{Li}_{2^n}^y = [t; 1 - \frac{t}{x_{n-1}}, x_{n-1}, 1 - \frac{x_{n-1}}{x_{n-2}}, x_{n-2}, \ldots, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1] \subset \mathbb{A}^1 \times \Box^{2n-1}.
\]

**Remark 3.17.**

- One finds back the expression given in \([\text{BK94}]\).
• Moreover, \( \mathcal{L}_n^{\mathcal{U}} \) corresponds to the function \( t \mapsto L_n^{\mathcal{U}}(t) \) as shown in [BK94] (or in [CCGL09]).

\( \mathcal{L}_0 \) having an empty fiber at 1, one can also pull-back by the twisted multiplication and obtain similarly cycles \( \mathcal{L}_{b_{01}} \) satisfying \( \partial(\mathcal{L}_{b_{01}}) = \partial(\mathcal{L}_{b_{001}}) \).

In some sense, they correspond to \( \mathcal{L}_{b_{01}} = p^* \circ i^*_1(\mathcal{L}_{b_{001}}) \) which in terms of integrals correspond to \( L_n^{\mathcal{U}}(t) \).

### 3.4. Some higher weight examples for multiple polylogarithm cycles.

#### 3.4.1. Weight 3.

The cycle \( \mathcal{L}_{01} \) was defined previously, so was the cycle \( \mathcal{L}_{001} = \mathcal{L}_1^{\mathcal{U}} \) by considering the product

\[
\mathcal{L}_{01} \cdot \mathcal{L}_1 \in \mathcal{N}_3^X.(3)
\]

Now, in weight 3, one could also consider the product

\[
\mathcal{L}_{01} \cdot \mathcal{L}_1 \in \mathcal{N}_3^Y(\mathcal{L}_1).
\]

However, the above product does not lead by similar arguments to a new cycle. Before explaining how to follows the strategy used in weight 2 and for the polylogarithms in order to obtain another weight 3 cycle, the author would like to spend a little time on the obstruction occurring with the above products as it enlighten particular the need of the cycle \( \mathcal{L}_{01} \) previously built.

Thus, let \( b = \mathcal{L}_{01} \cdot \mathcal{L}_1 \) be the above product in \( \mathcal{N}_3^X(3) \) and given as a parametrized cycle by

\[
b = [t; 1 - t/x_1, x_1, 1 - x_1, 1 - t] \subset X \times \square^4.
\]

From this expression, one sees that \( b \) is admissible and that \( \partial(b) = 0 \) because \( t \in X \) can not be equal to 1.

Let \( \mathcal{b} \) be the closure of the defining cycle of \( b \) in \( \mathbb{A}^1 \times \square^4 \), that is

\[
\mathcal{b} = \{ (t, 1 - t/x_1, x_1, 1 - x_1, 1 - t) \text{ such that } t \in \mathbb{A}^1, x_1 \in \mathbb{P}^1 \}.
\]

Let \( u_i \) denotes denote the coordinates on each factor \( \square^1 \). As most of the intersections of \( \mathcal{b} \) with face \( \mathbb{A}^1 \times F \) are empty, in order to prove that \( \mathcal{b} \) is admissible and give an element in \( \mathcal{N}_3^X(3) \) it is enough to check the (co)dimension condition on the three faces: \( u_1 = 0, u_4 = 0 \) and \( u_1 = u_4 = 0 \). The intersection of \( \mathcal{b} \) with the face \( u_1 = u_4 = 0 \) is empty as \( u_2 \neq 1 \). The intersection \( \mathcal{b} \) with the face defined by \( u_1 = 0 \) or \( u_4 = 0 \) is 1 dimensional and so of codimension 3 in \( \mathbb{A}^1 \times F \).

Computing the differential in \( \mathcal{N}_3^X \), using Lemma 3.1 or remarking that the intersection with \( u_1 = 0 \) is killed by the projector \( \mathcal{A}t \), gives

\[
\partial_{\mathbb{A}^1}(\mathcal{b}) = \partial_{\mathbb{A}^1}(\mathcal{L}_0 \mathcal{L}_{01}) = -\mathcal{L}_{01} | t=1 \neq 0
\]

and the homotopy trick used previously will not work as it relies (partially) on beginning with a cycle \( \mathcal{b} \) satisfying \( \partial_{\mathbb{A}^1}(\mathcal{b}) = 0 \).

In order to by pass this, one could introduce the constant cycle \( \mathcal{L}_{01}(1) = p^* \circ i^*_1(\mathcal{L}_{01}) \) and consider the linear combination

\[
\mathcal{b} = (\mathcal{L}_{01} - \mathcal{L}_{01}(1)) \cdot \mathcal{L}_1 \in \mathcal{N}_3^X(3).
\]

and its equivalent in \( \mathcal{N}_3^X(3) \). Now, the correction by \( -\mathcal{L}_{01}(1) \cdot \mathcal{L}_1 \) insures that \( \partial_{\mathbb{A}^1}(\mathcal{b}) = 0 \).

However, it is still not good enough as the using the homotopy property for the pull-back by the multiplication impose us to work with equidimensional cycles which is not the case for \( \mathcal{b} \) (the problem comes from the fiber at 1).
The fact that \( \overline{L}_1 \) is not equidimensional over \( \mathbb{A}^1 \) but equidimensional on \( \mathbb{A}^1 \setminus \{1\} \) requires to multiply it by a cycle with an empty fiber at 1 which insures that the fiber of the product at 1 is empty. Thus one considers the product in \( \mathcal{N}_{\mathbb{A}^1}^{eq,1}(3) \)

\[
\mathcal{B} = \overline{L}_{01} \overline{L}_1 = - \overline{L}_1 \overline{L}_{01}
\]

which has an empty fiber at 0 and 1. Moreover the Leibniz rule and Lemma 3.13 implies that

\[
\partial_b(\mathcal{B}) = \partial_{b^i}(L_{01}) \overline{L}_1 - \overline{L}_{01} \partial(\overline{L}_1) = \overline{L}_1 \partial \overline{L}_0 - \overline{L}_{01} |_{t=1} = 0.
\]

Thus, one defines

\[
(12) \quad \overline{L}_{011} = \mu^*(L_{01} \overline{L}_1) \quad \text{and} \quad \overline{L}_{011} = \nu^*(L_{01} \overline{L}_1)
\]

and their restrictions to \( X = \mathbb{P}^1 \setminus \{0, 1, \infty\} \)

\[
(13) \quad L_{011} = j^*(\overline{L}_{011}) \quad \text{and} \quad L_{011} = j^*(\overline{L}_{011}).
\]

As previously, propositions 3.12 and 3.10 insures the following.

**Lemma 3.18.** Cycles \( L_{011}, \overline{L}_{011}, L_{011}^1 \) and \( \overline{L}_{011}^1 \) satisfy the following properties

1. \( L_{011} \) and \( L_{011}^1 \) (resp. \( \overline{L}_{011} \) and \( \overline{L}_{011}^1 \)) are in \( \mathcal{N}_{X}^{eq,1}(2) \) (resp. in \( \mathcal{N}_{\mathbb{A}^1}^{eq,1}(2) \)).

2. They satisfy the following differential equations

\[
\partial(L_{011}) = \partial(L_{011}^1) = L_{01} L_1 = - L_1 L_{01}^1
\]

and \( \partial_b(L_{011}) = \partial_b(L_{011}^1) = \overline{L}_{01} \overline{L}_1. \)

3. The cycles \( L_{011} \) (resp. \( \overline{L}_{011}^1 \)) has an empty fiber at 0 (resp. at 1).

**3.4.2. Weight 4.** In weight 4 the first real linear combination appears. The situation in weight 4 is given by the following Lemma

**Lemma 3.19.** Let \( W \) be one of the Lyndon words 0001, 0011 or 0111. There exists cycles \( L_W, L_W^1 \) in \( \mathcal{N}_{X}^{eq,1}(4) \) and cycles \( \overline{L}_W, \overline{L}_W^1 \) in \( \mathcal{N}_{\mathbb{A}^1}^{eq,1}(4) \) which satisfy the following properties

1. \( L_W = j^*(\overline{L}_W) \) and \( L_W = j^*(\overline{L}_W) \)

2. \( \overline{L}_W \) (resp. \( \overline{L}_W^1 \)) has an empty fiber at 0 (resp. at 1)

3. Cycles \( L_W \) and \( L_W^1 \) for \( W = 0001, 0011 \) and 0111 satisfy the following differential equations derived from the differential equations satisfied by \( \overline{L}_W \) and \( \overline{L}_W^1 \)

\[
(14) \quad \partial(L_{0001}) = \partial(L_{0001}^1) = L_0 L_{001},
\]

\[
(15) \quad \partial(L_{0011}) = \partial(L_{0011}^1) = L_0 L_{011} + L_{001} L_1 - L_{01} L_{01}^1
\]

and

\[
(16) \quad \partial(L_{0111}) = \partial(L_{0111}^1) = L_{011} L_1.
\]

**Proof.** The proof goes as before as the main difficulties is to “guess” the differential equations. The case of \( L_{0001} = L_{0001}^q \) and \( L_{0001}^1 \) has already been treated in Lemma 3.10 and the remark afterward. The case of \( L_{0111} \) and \( L_{0111}^1 \) is extremely similar to the case of \( L_{0111} \). We will only describe the case of \( L_{0011} \). Let \( \mathcal{B} \) be the element in \( \mathcal{N}_{\mathbb{A}^1}^{eq}(4) \) defined by:

\[
\mathcal{B} = L_W L_{011} + L_{001} \overline{L}_1 - L_{01} \overline{L}_{01}^1.
\]

All the cycles involved are equidimensional over \( \mathbb{A}^1 \setminus \{0, 1\} \). As the products in the above equation always involve a cycle with empty fiber at 0 and one with empty fiber at 1, the product has empty fiber at 0 and 1 and is equidimensional over \( \mathbb{A}^3 \).
This shows that \( \overrightarrow{b} \) is equidimensional over \( \mathbb{A}^{1} \) with empty fiber at 0 and 1. One computes \( \partial_{\mathbb{A}^{1}}(\overrightarrow{b}) \) using Leibniz rules, Lemma 3.13 and the previously obtained differential equations:

\[
\partial_{\mathbb{A}^{1}}(\overrightarrow{b}) = -L_{0}L_{01}L_{1} + L_{0}L_{01}L_{1}^1 - L_{0}L_{1}L_{01} + L_{01}L_{0}L_{1} = 0
\]

Thus, one can define

\[
\overrightarrow{L}_{001} = \mu^*(\overrightarrow{b}) \quad \text{and} \quad \overrightarrow{L}_{1001} = \nu^*(\overrightarrow{b})
\]

and conclude with propositions 3.12 and 3.10.

3.4.3. General statement and a weight 5 example. In weight 5 there are six Lyndon words and the combinatorial of equation (ED-T) leads to six cycles with empty fiber at 0 and six cycles with empty fiber at 1. The general statement proved in [Sou12] is given below.

**Theorem 3.20.** For any Lyndon word of length \( p \) greater or equal to 2, there exists two cycles \( \mathcal{L}_{W} \) and \( \mathcal{L}_{W}^{1} \) in \( \mathcal{N}_{X}^{\nu}((p)) \) such that:

- \( \mathcal{L}_{W} \) and \( \mathcal{L}_{W}^{1} \) are elements in \( \mathcal{N}_{X}^{\nu,1}((p)) \).
- There exists cycles \( L_{W} \), \( L_{W}^{1} \) in \( \mathcal{N}_{X}^{\nu,1}((p)) \) such that
  \[
  \mathcal{L}_{W} = \mathcal{J}^*(L_{W}) \quad \text{and} \quad L_{W}^{1} = \mathcal{J}^*(L_{W}^{1}).
  \]
- The restriction of \( \mathcal{L}_{W} \) (resp. \( \mathcal{L}_{W}^{1} \)) to the fiber \( t = 0 \) (resp. \( t = 1 \)) is empty.
- The cycle \( \mathcal{L}_{W} \) satisfies the equation
  \[
  \partial(\mathcal{L}_{W}) = \sum_{U<V} a_{U,V}^{W} \mathcal{L}_{U} \mathcal{L}_{V} + \sum_{U,V} b_{U,V}^{W} \mathcal{L}_{U} \mathcal{L}_{V}^{1}
  \]
  and resp. \( \mathcal{L}_{W}^{1} \) satisfies
  \[
  \partial(\mathcal{L}_{W}^{1}) = \sum_{0<U<V} a_{U,V}^{W} \mathcal{L}_{U}^{1} \mathcal{L}_{V} + \sum_{U,V} b_{U,V}^{W} \mathcal{L}_{U} \mathcal{L}_{V}^{1} + \sum_{V} a_{0,V}^{W} \mathcal{L}_{0} \mathcal{L}_{V}
  \]
  and the same holds for their extensions \( \overrightarrow{L}_{W} \) and \( \overrightarrow{L}_{W}^{1} \) to \( \mathcal{N}_{X}^{\nu,1} \). In the above equations \( U \) and \( V \) are Lyndon words of smaller length than \( W \) and the coefficients \( a_{U,V}^{W}, b_{U,V}^{W}, a_{V}^{W}, b_{V}^{W}, a_{0,V}^{W}, b_{0,V}^{W} \) are derived from equation (ED-T).

**Remark 3.21.** Without giving a proof which works by induction on the length of \( W \), the author would like to stress that the construction of the cycles \( \overrightarrow{L}_{W} \) (resp. \( \overrightarrow{L}_{W}^{1} \)) relies on a geometric argument that has already been described and used here: the pull-back by the (twisted) multiplication \( \mu^* \) (resp. \( \nu^* \)) gives a homotopy between the identity and \( p^* \circ \tilde{t}_{0} \) (resp. \( p^* \circ \tilde{t}_{1} \)). Thus, Defining

\[
\overrightarrow{A}_{W} = \sum_{U<V} a_{U,V}^{W} \overrightarrow{L}_{U} \overrightarrow{L}_{V} + \sum_{U,V} b_{U,V}^{W} \overrightarrow{L}_{U} \overrightarrow{L}_{V}^{1}
\]

and

\[
\overrightarrow{A}_{W}^{1} = \sum_{0<U<V} a_{U,V}^{W} \overrightarrow{L}_{U}^{1} \overrightarrow{L}_{V} + \sum_{U,V} b_{U,V}^{W} \overrightarrow{L}_{U} \overrightarrow{L}_{V}^{1} + \sum_{V} a_{0,V}^{W} \overrightarrow{L}_{0} \overrightarrow{L}_{V},
\]

the cycle \( \overrightarrow{L}_{W} \) and \( \overrightarrow{L}_{W}^{1} \) are defined by

\[
\overrightarrow{L}_{W} = \mu^*(\overrightarrow{A}_{W}) \quad \text{and} \quad \overrightarrow{L}_{W}^{1} = \nu^*(\overrightarrow{A}_{W}).
\]

The fact that \( \overrightarrow{A}_{W} \) (resp. \( \overrightarrow{A}_{W}^{1} \)) is equidimensional over \( \mathbb{A}^{1} \) with empty fiber at 0 (resp. 1) is essentially a consequence of the induction. The main problem is to show that \( \partial_{\mathbb{A}^{1}}(\overrightarrow{A}_{W}) = \partial_{\mathbb{A}^{1}}(\overrightarrow{A}_{W}^{1}) = 0 \) which in [Sou12] is deduced after a long preliminary work from the combinatorial situation given by the trees \( T_{W} \).

In weight 5, appears the need of two distinct differential equation and the first example with coefficient different from \( \pm 1 \).
Example 3.22. The two cycles associated to the Lyndon word 01011 satisfy

\( \partial(L_{01011}) = -L_0 L_{011} - L_1 L_{011}^1 - 2L_{011} L_0^1 \) \hspace{1cm} (20)

\( \partial(L_{101011}^1) = L_0^1 L_{011}^1 - L_{011} L_0^1 - L_0 L_{011}^1 - L_1 L_{011}^1 \) \hspace{1cm} (21)

The factor 2 in the last term of \( \partial(L_{01011}) \) is related to the factor 2 appearing in \( d_{cy}(T_{01011} \cdot) \) presented at Equation (3). The term

\[ \partial(A_1^1(L_{01011})) = L_1 L_{01} L_{011} - L_{011} L_{01} - L_0 L_{011}^1 - L_{011} L_1 \]

arising from \( \partial(-2L_{011} L_{01}^1) \) cancel with one term in \(-L_0 L_{011} \) coming from \( \partial(-L_{01}) \), and one term in \( L_1 L_{01} L_{011} \) coming from \( \partial(L_{1} \cdot L_{011}) \). The whole computation can in fact be done over \( A_1 \) and \( L_{01011} \) is defined as previously as the pull-back by \( \mu^* \) of

\[ -L_0 L_{011} - L_1 L_{0111}^1 - 2L_{0111} L_0^1. \]

The cycle \( L_{01011} \) is then its restriction to \( X \). The above linear combination has an empty fiber at 0 (which allows the use of \( \mu^* \)). However its fiber at 1 is non empty and given by

\[ -L_0 |_{t=1} L_{011} |_{t=1} \]

and its pull-back by the twisted multiplication \( \nu^* \) satisfies

\[ \partial_{\nu^*}(\nu^*(\overline{b})) = \overline{\overline{b}} + p^* \circ i_1^* (\overline{b}) \neq \overline{b}. \]

That is why we have introduced the linear combination

\[ L_{01}^1 L_{011} - L_{011} L_{01} - L_0 L_{011}^1 - L_1 L_{011}^1 \]

whose extension to \( A_1 \) have empty fiber at 1 (but not at 0). This allows us to define

\[ \overline{L_{01011}} = \nu^* (L_{01}^1 L_{011} - L_{011} L_{01} - L_0 L_{011}^1 - L_1 L_{011}^1). \]

4. Parametric and combinatorial representation for the cycles: trees with colored edges

One can give a combinatorial approach to describe cycles \( L_W \) and \( L_{1W}^1 \) as parametrized cycles using trivalent trees with two types of edge.

Definition 4.1. Let \( T^{||} \) be the \( \mathbb{Q} \) vector space spanned by rooted trivalent trees such that

- the edges can be of two types: \( | \) or \( || \);
- the root vertex is decorated by \( t \);
- other external vertices are decorated by 0 or 1.

We say that such a tree is a rooted colored tree or simply a colored tree.

We define two bilinear maps \( T^{||} \otimes T^{||} \longrightarrow T^{||} \) as follows on the colored trees:

- Let \( T_1 \upharpoonleft T_2 \) be the colored tree given by joining the two root of \( T_1 \) and \( T_2 \)
  and adding a new root and a new edge of type \( | \):

\[ T_1 \upharpoonleft T_2 = \begin{array}{c}
\begin{array}{c}
T_1
\end{array}
\end{array} \]

where the dotted edges denote either type of edges.
• Let $T_1 \Lambda T_2$ be the colored tree given by joining the two root of $T_1$ and $T_2$
and adding a new root and a new edge of type $\parallel$:

$$T_1 \Lambda T_2 = \begin{array}{c}
T_1 \\
\downarrow \\
T_2
\end{array}$$

where the dotted edges denote either type of edges.

**Definition 4.2.** Let $T_0$ and $T_1$ be the colored tree defined by

$$T_0 = \begin{array}{c}
\ast \\
\circ \\
\ast
\end{array} \quad \text{and} \quad T_1 = \begin{array}{c}
\circ \\
\ast \\
\ast
\end{array}.$$

For any Lyndon word $W$ of length greater or equal to 2, let $T_W$ (resp. $T_W^1$) be the linear combination of colored trees given by

$$T_W = \sum_{U < V} a_{U,V}^W T_U \Lambda T_V + \sum_{U,V} b_{U,V}^W T_U \Lambda T_V,$$

and respectively by

$$T_W^1 = \sum_{0 < U < V} a_{U,V}^W T_U \Lambda T_V + \sum_{U,V} b_{U,V}^W T_U \Lambda T_V + \sum a_{0,V}^W T_0 \Lambda T_V.$$

where the coefficients appearing are the one from Theorem 3.20.

To a colored tree $T$ with $p$ external leaves and a root, one associates a function $f_T : X \times (\mathbb{P}^1)^{p-1} \rightarrow X \times (\mathbb{P}^1)^{2p-1}$ as follows:

• Endow $T$ with its natural order as trivalent tree.
• This induces a numbering of the edges of $T$ : $(e_1, e_2, \ldots, e_{2p-1})$.
• The edges being oriented away from the root, the numbering of the edges induces a numbering of the vertices, $(v_1, v_2, \ldots, v_{2p})$ such that the root is $v_1$.
• Associate variables $x_1, \ldots, x_{p-1}$ to each internal vertices such that the numbering of the variable is opposite to the order induced by the numbering of the vertices (first internal vertices has variable $x_{p-1}$, second internal vertices has variable $x_{p-2}$ and so on).

• For each edge $e_i = \begin{array}{c}
a \\
b
\end{array}$ oriented from $a$ to $b$, define a function

$$f_i(a, b) = \begin{cases}
1 - \frac{a}{b} & \text{if } e_i \text{ is of type } \nabla, \\
\frac{b - a}{b - 1} & \text{if } e_i \text{ is of type } \parallel.
\end{cases}$$

• Finally $f_T : X \times (\mathbb{P}^1)^{p-1} \rightarrow X \times (\mathbb{P}^1)^{2p-1}$ is defined by

$$f_T(t, x_1, \ldots, x_{p-1}) = (t, f_1, \ldots, f_{2p-1}).$$

Let $\Gamma(T)$ be the intersection of the the image of $f_T$ with $X \times \mathbb{P}^{2p-1}$. One extends the definition of $\Gamma$ to $T^\parallel$ by linearity and thus obtains a twisted forest cycling map similar to the one defined by Gangl, Goncharov and Levin in [GGL09].

The map $\Gamma$ satisfies:

• $\text{Alt}(\Gamma(T_0)) = L_0$ and $\text{Alt}(\Gamma(T_1)) = L_1$.
• For any Lyndon word of length $p \geq 2$,

$$\text{Alt}(\Gamma(T_W)) = L_W \quad \text{and} \quad \text{Alt}(\Gamma(T_W^1)) = L_W^1.$$
The fact that $\Gamma(\Sigma_0)$ (resp. $\Gamma(\Sigma_1)$) is the graph of $t \mapsto t$ (resp. $t \mapsto 1 - t$) follows from the definition. Thus, one already has $\Gamma(\Sigma_0)$ (resp. $\Gamma(\Sigma_1)$) in $Z_{eq}^1(X, 1)$ and $\text{Alt}(\Gamma(\Sigma_0)) = L_0$ and $\text{Alt}(\Gamma(\Sigma_1)) = L_1$.

Then, the above property is deduced by induction. Recall that the defining equation \[10\] for the cycle $L_W$ is

$$L_W = \mu^* \left( \sum_{U<V} q_{U,V}^W L_U L_V + \sum_{U,V} b_{U,V}^W L_U L_V \right).$$

As already remarked in Example 2.3 in order to compute the pull-back by $\mu^*$ one sets the former parameter $t$ to a new variable $x_n$ and parametrizes the new $\square^1$ factor arriving in first position by $1 - \frac{t}{x_n}$; $t$ is again the parameter over $X$ or $\mathbb{A}^1$ depending if one considers cycles over $\mathbb{A}^1$ or their restriction to $X = \mathbb{P}^1 \setminus \{0, 1, \infty\}$. Thus the expression of $L_W$, restriction of $L_W$ to $X$ is exactly given by

$$L_W = \text{Alt}(\Gamma(\Sigma_W)).$$

The case of $\nu^*$ is similar but parametrizing the new $\square^1$ factor by $\frac{x_n - 1}{x_n}$.

For the previously built examples, we gives below the corresponding colored trees and expression as parametrized cycle (omitting the projector $\text{Alt}$). We also recall the corresponding differential equations as given by Theorem 3.20.

**Example 4.3 (Weight 1).**

$$\Sigma_0 = \begin{array}{c} 0 \\ 1 \end{array}, \quad \Sigma_1 = \begin{array}{c} 0 \\ 1 \end{array} \quad \text{and} \quad \partial(L_0) = \partial(L_1) = 0.$$

We recall below how cycles $L_0$ and $L_1$ are expressed in terms of parametrized cycles.

$$L_0 = [t; t] \subset X \times \square^1 \quad \text{and} \quad L_1 = [t; 1 - t] \subset X \times \square^1.$$

**Example 4.4 (Weight 2).**

$$\Sigma_{01} = \begin{array}{cc} 0 & 1 \\ 0 & 1 \end{array}, \quad \Sigma_{10} = \begin{array}{cc} 0 & 1 \\ 1 & 1 \end{array} \quad \text{and} \quad \partial(L_{01}) = \partial(L_{10}) = L_0 L_1.$$ 

As we have seen in Equation \[20\], cycles $L_{01}$ and $L_{10}$ are given by

$$L_{01} = [t; \frac{1 - t}{x_1}, x_1, 1 - x_1] \subset X \times \square^3 \quad \text{and} \quad L_{10} = [t; \frac{x_1 - t}{x_1 - 1}, x_1, 1 - x_1] \subset X \times \square^3.$$

**Example 4.5 (Weight 3).**

$$\partial(L_{001}) = \partial(L_{101}) = L_0 L_1, \quad \partial(L_{011}) = \partial(L_{111}) = -L_1 L_{01}.$$ 

The corresponding expression as parametrized cycles are given below (following our “twisted forest cycling map”):

$$L_{001} = [t; 1 - \frac{t}{x_2}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1] \subset X \times \square^5,$$

$$L_{101} = [t; \frac{x_2 - t}{x_2 - 1}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1] \subset X \times \square^5.$$
and

\[ \mathcal{L}_{011} = -\left[t; 1 - \frac{t}{x_2}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1 \right] \subset X \times \mathbb{D}^5, \]

\[ \mathcal{L}'_{011} = -\left[t; \frac{x_2 - t}{x_2 - 1}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1 \right] \subset X \times \mathbb{D}^5. \]

**Example 4.6 (Weight 4).** The differential equations satisfied by the weight 4 cycles are:

\[ \partial(\mathcal{L}_{0001}) = \partial(\mathcal{L}'_{0001}) = \mathcal{L}_0 \mathcal{L}_{001} \]

\[ \partial(\mathcal{L}_{0011}) = \partial(\mathcal{L}'_{0011}) = \mathcal{L}_0 \mathcal{L}_{011} - \mathcal{L}_1 \mathcal{L}'_{001} - \mathcal{L}_{01} \mathcal{L}'_{01} \]

\[ \partial(\mathcal{L}_{0111}) = \partial(\mathcal{L}'_{0111}) = -\mathcal{L}_1 \mathcal{L}'_{011} \]

The corresponding colored trees are given by:

\[ \Sigma_{0001} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma'_{0001} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma_{0111} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma'_{0111} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} \]

and

\[ \Sigma_{0011} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma'_{0011} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma_{0111} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} , \quad \Sigma'_{0111} = \begin{array}{c}
\begin{array}{ccc}
\circ & \circ & \circ \\
0 & 0 & 0 \\
1 & 1 & 1
\end{array}
\end{array} \]

The expressions as parametrized cycles of \( \mathcal{L}_{0001}, \mathcal{L}'_{0001}, \mathcal{L}_{0111} \) and \( \mathcal{L}'_{0111} \) are given below (in \( X \times \mathbb{D}^5 \)):

\[ \mathcal{L}_{0001} = \left[t; 1 - \frac{t}{x_3}, x_3, 1 - \frac{x_3}{x_2}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right], \]

\[ \mathcal{L}'_{0001} = \left[t; \frac{x_3 - t}{x_3 - 1}, x_3, 1 - \frac{x_3}{x_2}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right], \]

\[ \mathcal{L}_{0111} = \left[t; 1 - \frac{t}{x_3}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right], \]

\[ \mathcal{L}'_{0111} = \left[t; \frac{x_3 - t}{x_3 - 1}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right], \]

while the expressions for \( \mathcal{L}_{0011} \) and \( \mathcal{L}'_{0111} \) involved linear combinations:

\[ \mathcal{L}_{0011} = \left[-t; 1 - \frac{t}{x_3}, x_3, 1 - \frac{x_3}{x_2}, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1 \right] \]

\[ - \left[t; 1 - \frac{t}{x_3}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right] \]

\[ - \left[t; 1 - \frac{t}{x_3}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1 \right] \]
The corresponding expression as parametrized cycles are given below (in $X \times \square^9$):

\[
\begin{align*}
\mathcal{L}_{01011}^1 &= [t; \frac{x_3 - t}{x_3 - 1}, x_3, 1 - x_3, 1 - x_2, \frac{x_1 - x_2}{x_2 - 1}, x_1, 1 - x_1] \\
&\quad + [t; \frac{x_3 - t}{x_3 - 1}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - x_1, x_1, 1 - x_1] \\
&\quad + [t; \frac{x_3 - t}{x_3 - 1}, 1 - x_3, x_2, 1 - x_2, \frac{x_1 - x_3}{x_1 - 1}, x_1, 1 - x_1].
\end{align*}
\]

Example 4.7 (Weight 5). The differential equation satisfied by $\mathcal{L}_{01011}$ and $\mathcal{L}_{01011}^1$ are:

\[
\begin{align*}
d\mathcal{L}_{01011} &= -\mathcal{L}_{01} \cdot \mathcal{L}_{011} - \mathcal{L}_1 \mathcal{L}_{0011} - 2\mathcal{L}_{011} \mathcal{L}_{01} \\
d\mathcal{L}_{01011}^1 &= \mathcal{L}_{01} \cdot \mathcal{L}_{011} - \mathcal{L}_{011} \cdot \mathcal{L}_{01} - \mathcal{L}_{01} \cdot \mathcal{L}_{011} - \mathcal{L}_1 \cdot \mathcal{L}_{0011}.
\end{align*}
\]

The corresponding colored trees are given by:

\[
\begin{align*}
\mathcal{T}_{01011} &= + \quad + \quad + \quad + \quad + 2
\end{align*}
\]

\[
\begin{align*}
\mathcal{T}_{01011}^1 &= - \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
&\quad + \\
\end{align*}
\]

The corresponding expression as parametrized cycles are given below (in $X \times \square^9$):

\[
\begin{align*}
\mathcal{L}_{01011} &= [t; 1 - \frac{t}{x_4}, 1 - x_4, x_3, 1 - x_3, 1 - x_2, \frac{x_1 - x_2}{x_2 - 1}, x_1, 1 - x_1] \\
&\quad + [t; 1 - \frac{t}{x_4}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, x_3, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - x_2, x_1, 1 - x_1] \\
&\quad + [t; 1 - \frac{t}{x_4}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, x_3, 1 - x_3, 1 - x_2, \frac{x_1 - x_3}{x_1 - 1}, x_1, 1 - x_1] \\
&\quad + [t; 1 - \frac{t}{x_4}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, 1 - x_3, x_2, 1 - x_2, \frac{x_1 - x_3}{x_1 - 1}, x_1, 1 - x_1] \\
&\quad + 2[t; 1 - \frac{t}{x_4}, 1 - x_4, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - x_2, \frac{x_1 - x_4}{x_1 - 1}, x_1, 1 - x_1].
\end{align*}
\]
and
\[ L_{0101}^1 = -[t; \frac{x_4 - t}{x_4 - 1}, \frac{x_4}{x_4 - 1}, 1 - x_3, \frac{x_2 - x_4}{x_2 - 1}, \frac{1 - x_2}{x_2 - 1}, \frac{1 - x_2}{x_2 - 1}, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1] \]
\[ + [t; \frac{x_4 - t}{x_4 - 1}, x_3, 1 - x_3, \frac{x_2 - x_4}{x_2 - 1}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1] \]
\[ + [t; \frac{x_4 - t}{x_4 - 1}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, x_3, 1 - x_2, \frac{x_2 - x_3}{x_2 - 1}, \frac{1 - x_2}{x_2 - 1}, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1] \]
\[ + [t; \frac{x_4 - t}{x_4 - 1}, 1 - x_2, \frac{x_3 - x_4}{x_3 - 1}, x_3, 1 - x_2, \frac{x_2 - x_3}{x_2 - 1}, \frac{1 - x_2}{x_2 - 1}, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1] \]
\[ + [t; \frac{x_4 - t}{x_4 - 1}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1] \]
\[ + [t; \frac{x_4 - t}{x_4 - 1}, 1 - x_4, \frac{x_3 - x_4}{x_3 - 1}, 1 - x_3, \frac{x_2 - x_3}{x_2 - 1}, x_2, 1 - x_2, \frac{x_1 - x_3}{x_1 - 1}, x_1, 1 - x_1]. \]

5. Bar construction settings

In the cycles motives setting, a motive over \( X \) is a comodule on the \( H^0 \) of the bar construction over \( N_X^* \) modulo shuffle product (see \([BK94, Spi01\) and \([Lev11\)]\)).

In this context, the cycles constructed above, which are expected to correspond to multiple polylogarithms, induce elements in this \( H^0 \) and naturally gives rise to an associated comodule, thus to mixed Tate motives corresponding to multiple polylogarithms.

Before giving explicit expression for the induced elements in the bar construction, the beginning of the section is devoted to a short review of the bar construction.

5.1. Bar construction. As there do not seem to exist a global sign convention for the various operation on the bar construction, the main definitions in the cohomological setting are recalled below following the (homological) description given in \([VL12\])

Let \( A \) be a c.d.g.a with augmentation \( \varepsilon : A \rightarrow \mathbb{Q} \), with product \( \mu_A \) and let \( A^+ \) be the augmentation ideal \( A^+ = \ker(\varepsilon) \).

In order to understand the sign convention below and the “bar grading”, one should think of the bar construction as built on the tensor coalgebra over the shifted (suspended) graded vector space \( A^+[1] \).

**Definition 5.1.** The bar construction \( B(A) \) over \( A \) is the tensor coalgebra over the suspension of \( A^+ \)

- In particular, as vector space \( B(A) \) is given by:
  \[ B(A) = T(A^+) = \bigoplus_{n \geq 0} (A^+) \otimes I. \]

- An homogeneous element \( a \) of tensor degree \( n \) is denoted using the bar notation, that is
  \[ a = [a_1] \ldots [a_n] \]

  and its degree is
  \[ \deg_B(a) = \sum_{i=1}^{n} \deg_A(a_i) - 1. \]

- The coalgebra structure comes from the natural deconcatenation coproduct, that is
  \[ \Delta([a_1] \ldots [a_n]) = \sum_{i=0}^{n} [a_1] \ldots [a_i] \otimes [a_{i+1}] \ldots [a_n]. \]**
Remark 5.2. This construction can be seen as a simplicial total complex associated to the complex $A$ (Cf. [BK94]). The augmentation makes it possible to use directly $A^+$ without referring the tensor coalgebra over $A$ and without the need of killing the degeneracies.

However this simplicial presentation usually masks the need of working with the shifted complex.

We associate to any bar element $[a_1] \ldots [a_n]$ the function $\eta(i)$ giving its “partial” degree

$$\eta(i) = \sum_{k=1}^{i} (\deg_{A}(a_k) - 1).$$

The original differential $d_A$ induces a differential $D_1$ on $B(A)$ given by

$$D_1([a_1] \ldots [a_n]) = -\sum_{i=1}^{n} (-1)^{\eta(i)}[a_1] \ldots [d_A(a_i)] \ldots [a_n]$$

where the initial minus from comes from the fact the differential on the shifted complex $A[1]$ is $-d_A$. Moreover, the multiplication on $A$ induces another differential $D_2$ on $B(A)$ given by

$$D_2([a_1] \ldots [a_n]) = -\sum_{i=1}^{n} (-1)^{\eta(i)}[a_1] \ldots [\mu_{A}(a_i, a_{i+1})] \ldots [a_n]$$

where the signs are coming from Koszul commutation rules (due to the shifting). One checks that the two differentials anticommutes providing $B(A)$ with a total differential.

Definition 5.3. The total differential on $B(A)$ is defined by

$$d_{B(A)} = D_1 + D_2.$$

The last structure arising with the bar construction is the graded shuffle product

$$[a_1] \ldots [a_n] \blacksquare [a_{n+1}] \ldots [a_{n+m}] = \sum_{\sigma \in sh(n, m)} (-1)^{\varepsilon_{\mu}(\sigma)}[a_{\sigma(1)}, \ldots, a_{\sigma(n+m)}]$$

where $sh(n, m)$ denotes the permutation of $\{1, \ldots, n+m\}$ such that if $1 \leq i < j \leq n$ or $n+1 \leq i < j \leq n+m$ then $\sigma(i) < \sigma(j)$. The sign is the graded signature of the permutation (for the degree in $A^+[1]$) given by

$$\varepsilon_{gr}(\sigma) = \sum_{i < j \atop \sigma(i) > \sigma(j)} (\deg_{A}(a_i) - 1)(\deg_{A}(a_j) - 1).$$

With this definitions, one can explicitly check the following

Proposition 5.4. Let $A$ be a (Adams/weight graded) c.d.g.a. The operations $\Delta$, $d_{B(A)}$ and $\mu$ together with the obvious unit and counit give $B(A)$ a structure of (Adams graded) commutative graded differential Hopf algebra.

In particular, these operations induced on $H^0(B(A))$, and more generally on $H^*(B(A))$, a (Adams graded) commutative Hopf algebra structure. This (Adams) algebra is cohomologically graded in the case of $H^*(B(A))$ and cohomologically graded concentrated in degree 0 in the case of $H^0(B(A))$.

We recall that the set of indecomposable elements of an augmented c.d.g.a is defined as the augmentation ideal $I$ modulo products, that is $I/I^2$. Applying a general fact about Hopf algebra, the coproduct structure on $H^0(B(A))$ induces a coLie algebra structure on its set of indecomposables.
5.2. Bar elements. Considering the bar construction over $N^*_X$, part of the issue is to associate to any cycle $L_W$ and $L_W^1$ a corresponding element in $H^0(B(N^*_X))$.

As weight 1 cycles $L_0$ and $L_1$ have 0 differential in $N^*_X$, there are obvious corresponding bar elements:

$$L_0^B = [L_0] \quad \text{and} \quad L_1^B = [L_1].$$

Let $M_X$ denotes the indecomposable elements of $H^0(B(N^*_X))$ and let $\tau$ the morphism exchanging the two factors of $H^0(B(N^*_X)) \otimes H^0(B(N^*_X))$. We denote by $d_\Delta = \Delta - \tau \Delta$ the differential on the coLie algebra $M_X$ induced by the coproduct on $H^0(B(N^*_X))$. In general, one should have the following.

Claim. For any Lyndon word $W$ (of length greater or equal to 2), there exists elements $L_W^B$ and $L_W^{1,B}$ in $B(N^*_X)$ of bar degree 0 satisfying:

- Let $d_B$ denotes the bar total differential $d_B = d_B(N^*_X)$
  $$d_B(L_W^B) = d_B(L_W^{1,B}) = 0.$$

- The tensor degree 1 part of $L_W^B$ (resp. $L_W^{1,B}$) is given by $[L_W]$ (resp. $[L_W^1]$).

- Elements $L_W^B$ (resp. $L_W^{1,B}$) satisfy the differential equation (17) (resp. (18)) in $M_X$. That is
  $$d_\Delta(L_W^B) = - \left( \sum_{U < V} a_{U,V}^W L_U^B L_V^B + \sum_{U,V} b_{U,V}^W L_U^B L_V^1 \right) \in M_X \wedge M_X$$

and
  $$d_\Delta(L_W^{1,B}) = - \left( \sum_{0 < U < V} d_{U,V}^W L_U^{1,B} L_V^1 + \sum_{U,V} b_{U,V}^W L_U^B L_V^1 + \sum_{V} d_{0,V}^W L_0^B L_V^B \right) \in M_X \wedge M_X$$

where the overall minus sign is due to shifting reasons.

The obstruction for proving the general statement lies in the control of the global combinatoric relating $D_1, D_2$ and the two systems of differential equations. The author hope to prove the claim in a near future but is unfortunately not at this point yet.

Below, one finds some elements $L_W^B$ and $L_W^{1,B}$ corresponding to the previously described examples together with some relations among those elements. Once the element $L_W^B$ explicitly described, it is a straightforward computation to check that it lies in the kernel of $d_B$ and this verification will be omitted.

Note that all cycles $L_W$ and $L_W^1$ are in cohomological degree 1, that is in $N^*_X$; thus, signs appearing in the operations on the bar construction are much simpler as all terms in $\deg_\Lambda(a_i) - 1 = 0$.

Example 5.5 (Weight 2). Cycles $L_{01}$ and $L_{10}$ satisfy $\partial(L_{01}) = \partial(L_{10}) = L_0 L_1$. Thus one can define

$$L_{01}^B = [L_{01}] - \frac{1}{2} ([L_0][L_1] - [L_1][L_0]) \quad \text{and} \quad L_{01}^{1,B} = [L_{01}] - \frac{1}{2} ([L_0][L_1] - [L_1][L_0]).$$

Remark that, looking at things modulo products, that is in $M_X$, the tensor degree 2 involves some choices. Instead of

$$-\frac{1}{2} ([L_0][L_1] - [L_1][L_0])$$
we could have use

\[-[\mathcal{L}_0|\mathcal{L}_1] \quad \text{or} \quad [\mathcal{L}_1|\mathcal{L}_0]\]

and obtain the same elements in \(\mathcal{M}_X\) as

\[-\frac{1}{2}([\mathcal{L}_0|\mathcal{L}_1] | [\mathcal{L}_1|\mathcal{L}_0]) = -[\mathcal{L}_0|\mathcal{L}_1] + \frac{1}{2}\mathcal{L}_0^B \in \mathcal{L}_1^B = [\mathcal{L}_1|\mathcal{L}_0] - \frac{1}{2}\mathcal{L}_0^B \in \mathcal{L}_1^B.\]

The above choice, reflect in some sense that there is no preference between writing

\[\partial(\mathcal{L}_{01}) = \partial(\mathcal{L}_{10}) = \mathcal{L}_0 \mathcal{L}_1 \quad \text{or} \quad \partial(\mathcal{L}_{01}) = \partial(\mathcal{L}_{10}) = -\mathcal{L}_1 \mathcal{L}_0.\]

Recall that we have defined a cycle \(\mathcal{L}_{01}(1)\) in \(\mathcal{N}_X^1\) by

\[\mathcal{L}_{01}(1) = j^*(p^* \circ i_1^*(\mathcal{L}_{01}))\]

Building the cycle \(\mathcal{L}_{011}\), we have introduce the cycle \(\mathcal{L}_{01}^B\) instead of using the difference \(\mathcal{L}_{01} - \mathcal{L}_{01}(1)\) in order to keep working with equidimensional cycles. The “correspondence”

\[\mathcal{L}_{01}^B \leftrightarrow \mathcal{L}_{01} - \mathcal{L}_{01}(1)\]

becomes an equality in \(H^0(B(\mathcal{N}_X^1))\).

More precisely, using either the commutation of the above morphism with the differential or the expression of \(\mathcal{L}_{01}(1)\) as parametrized cycle, one sees that \(\partial(\mathcal{L}_{01}(1)) = 0\) and one defines

\[\mathcal{L}_{01}^B(1) = [\mathcal{L}_{01}(1)].\]

A direct computation show that

\[\mathcal{L}_{01}(1) = [t; 1 - \frac{1}{x_1}, x_1, 1 - x_1].\]

Now, from the expressions of \(\mathcal{L}_{01}, \mathcal{L}_{01}(1)\) and \(\mathcal{L}_{01}^B\) as parametrized cycles, one checks that in \(\mathcal{N}_X^1\)

\[\mathcal{L}_{01} - \mathcal{L}_{01}(1) = \mathcal{L}_{01}^B + \partial(C_{01})\]

where \(C_{01}\) is the element of \(\mathcal{N}_X^0\) defined by

\[C_{01} = -[t; y - \frac{x_1}{x_1}, x_1, 1 - x_1] \subset X \times \square^4.\]

The bar element \(\mathcal{C}_{01}^B = [C_{01}]\) is of bar degree \(-1\) and thus gives in \(B(\mathcal{N}_X^1)\)

\[\mathcal{L}_{01}^B - \mathcal{L}_{01}^B(1) = \mathcal{L}_{01}^B - d_B(C_{01})\]

and the equality \(\mathcal{L}_{01}^B - \mathcal{L}_{01}^B(1) = \mathcal{L}_{01}^B\) in the \(H^0\).

For this weight 2 examples, computing the deconcatenation coproduct is trivial and gives the expected relation

\[d_\Delta(\mathcal{L}_{01}^B) = d_\Delta(\mathcal{L}_{01}^B) = -\mathcal{L}_{01}^B \wedge \mathcal{L}_{01}^B.\]

Finally the motive corresponding to \(\mathcal{L}_{01}\) is the comodule generated by \(\mathcal{L}_{01}\), that is the subvector space of \(\mathcal{M}_X\) spanned by \(\mathcal{L}_{01}^B, \mathcal{L}_0^B\) and \(\mathcal{L}_1^B\).

**Example 5.6 (Weight 3).** The differential of \(\mathcal{L}_{001}, \mathcal{L}_{101}, \mathcal{L}_{111}\) allows to easily write down the corresponding tensor degree 1 and 2. The expressions below try to keep a symmetric presentation for the part in tensor degree 3.

In the equations below cycle \(\mathcal{L}_W\) are simply denoted by \(W\) and cycles \(\mathcal{L}_W^1\) simply by \(W\). We will also use this abuse of notation latter on in weight 4 and 5. One defines

\[
\mathcal{L}_{001}^B = [001] - \frac{1}{2}([0][01] - [01][0]) + \frac{1}{4}([0][0][1] - [0][1][0] + [1][0][0]),
\]

\[
\mathcal{L}_{001}^1 = [001] - \frac{1}{2}([0][01] - [01][0]) + \frac{1}{4}([0][0][1] - [0][1][0] + [1][0][0]).
\]
and
\[ L_{011}^B = [011] - \frac{1}{2} ([01][1] - [1][01]) + \frac{1}{4} ([0][1][1] - [1][0][1] + [0][1][1]), \]
\[ L_{011}^{1,B} = [011]T - \frac{1}{2} ([01][1] - [1][01]) + \frac{1}{4} ([0][1][1] - [1][0][1] + [0][1][1]). \]

As cycles \( L_{001} \) and \( L_{001}^1 \) (resp. \( L_{011} \) and \( L_{011}^{1,B} \)) differ only by their first \( \square^1 \) factors, the arguments used to compare \( L_{001}^B \) and \( L_{011}^{1,B} \) apply here and give:
\[ L_{001}^B - L_{001}^B(1) = L_{001}^{1,B} \quad \text{and} \quad L_{001}^B - L_{001}^B(1) = L_{001}^{1,B} \in \mathcal{M}_X. \]

The “correction” cycles giving the explicit relations between the cycles are
\[ C_{001} = [-t; s - \frac{x_2 - t}{x_2}, x_2, 1 - \frac{x_2}{x_1}, x_1, 1 - x_1] \]
and
\[ C_{011} = [t; s - \frac{x_2 - t}{x_2}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1]. \]

Now, computing the reduced coproduct \( \Delta' = \Delta - 1 \otimes \text{id} - \text{id} \otimes 1 \) of \( L_{001}^B \) gives:
\[ \Delta'(L_{001}^B) = -\frac{1}{2} ([0] \otimes [01] - [01] \otimes [0]) \]
\[ + \frac{1}{4} ([0] \otimes [01] - [0] \otimes [1][0] + [1] \otimes [0][0]) \]
\[ + [0][0] \otimes [1] - [0][1] \otimes [0] + [1][0] \otimes [0]). \]

As \([0][0] = 1/2 L_0^B \) in \( L_0^B \), one has modulo product
\[ \Delta'(L_{001}^B) = -\frac{1}{2} \left( [0] \otimes \left([01] - \frac{1}{2} ([0][1] - [1][0]) \right) \right) - \left([01] - \frac{1}{2} ([0][1] - [1][0]) \right) \otimes [0]. \]

Similar computations apply to \( L_{011}^{1,B} \), \( L_{011}^B \) and \( L_{011}^{1,B} \) and give in \( \mathcal{M}_X \cap \mathcal{M}_X \):
\[ d_B(L_{001}^{1,B}) = d_B(L_{001}^B) = L_0^B \wedge L_{01}^B \quad \text{and} \quad d_B(L_{011}^{1,B}) = d_B(L_{011}^B) = L_{01}^B \wedge L_1^B. \]

One should remark that, the equality \( L_{01}^{1,B} = L_{01}^B - L_{01}^B(1) \) implies
\[ (24) \quad d_B(L_{011}^B) = (L_{01}^B - L_{01}^B(1)) \wedge L_1^B \]
which is exactly the equation satisfied by \( T_{011} \), as shown at Example 2.13.

Finally, the corresponding comodule giving motives associated to the cycle \( L_{001} \)
and \( L_{011} \) are the subvector space of \( \mathcal{M}_X \) generated respectively by
\[ \langle L_{001}^B, L_{01}^B, L_1^B \rangle \]
and
\[ \langle L_{001}^B, L_{01}^B, L_{01}^B(1), L_0^B, L_1^B \rangle. \]

The above arguments apply similarly in weight 4. Hence, we will describe below
the case of \( L_{0011} \) as it gives a “preview” of the combinatorial difficulties related to
the bar construction context.
Example 5.7 (Weight 4 : $L_{0011}^B$). We give below an element $L_{0011}^B$ in the bar construction with zero differential corresponding to $L_{0011}$.

\begin{align}
(25) & \text{ } \quad L_{0011}^B = [0011] - \frac{1}{2} ([0][011] - [0][011] + [0][101] - [1][001] - [01][01] + [01][01]) \\
(26) & \quad + \frac{1}{4} (-[0][01] + [01][01] - [01][01] + [0][01]0 - [1][010] + [01][01]0 + [01][01]) \\
(27) & \quad - [0][01] + [1][001] + [01][001] + [0][011]0 + [001][0] + [0][011]1) \\
(28) & \quad - \frac{1}{2} (00011) - [1][0][0])
\end{align}

Identifying the reduced coproduct of $L_{0011}^B$ with

\begin{equation}
- \frac{1}{2} \left( L_0^B \otimes L_{011}^B - L_{011}^B \otimes L_0^B + L_{001}^B \otimes L_1^B - L_1^B \otimes L_{001}^B - L_{01}^B \otimes L_{01}^B + L_{01}^B \otimes L_{01}^B \right)
\end{equation}

is more difficult than in the previous cases. First of all, one remarks that in the above expression terms in $(N_1^X)^{\otimes 2} \otimes (N_1^X)^{\otimes 2}$ are coming only from $-L_{01}^B \otimes L_{01}^B$, and $L_{01}^B \otimes L_{01}^B$ and cancel each other. In the other hand, terms in $(N_1^X)^{\otimes 2} \otimes (N_1^X)^{\otimes 2}$ coming from $\Delta'(L_{0011}^B)$ are given by

\begin{align}
- \frac{1}{2} (00011) - [1][0][0]) = - \frac{1}{4} (L_0^B \otimes L_0^B, \otimes L_1^B \otimes L_1^B - L_1^B \otimes L_0^B \otimes L_0^B)
\end{align}

and thus zero in $M_X \wedge M_X$.

Terms in $N_1^X \otimes N_1^X$ in the above expression (29) obviously agree with the corresponding terms of $\Delta'(L_{0011}^B)$ as its tensor degree 2 is written down that way.

Computation below are done in $B(N_1^X) \otimes B(N_1^X)$. They will induce the expected relation in $M_X \wedge M_X$ after going to the $H^0$ and taking the quotient modulo shuffle product. Let $\pi_n : B(N_1^X) \rightarrow (N_1^X)^{\otimes n}$ be the projection to the $n$-th tensor factor. From the above discussion it is enough to compute $\Delta'(\pi_3(L_{0011}^B))$ and part of $\Delta'(\pi_4(L_{0011}^B))$.

First, the definition of the coproduct gives

\begin{align}
\Delta'(\pi_3(L_{0011}^B)) = & \left( -\frac{1}{2} \right) \left( -\frac{1}{2} \right) \left( [0] \otimes [0][0][1] + [0][01] \otimes [1] - [01] \otimes [0][1] - [01] \otimes [0][0][1]) \\
+ & \left( -\frac{1}{2} \right) \left( \frac{1}{2} \right) \left( -[0] \otimes [1][0] - [0][01] \otimes [1] + [01] \otimes [1][0] + [1][0] \otimes [0][1]) \\
+ & \left( -\frac{1}{2} \right) \left( -\frac{1}{2} \right) (-1) \left( [1][0] \otimes [0] + [1][0][01] - [01] \otimes [0][1] - [0][0][1] \otimes [0][1]) \\
+ & \left( -\frac{1}{2} \right) \left( -\frac{1}{2} \right) (-1) \left( [0][0] \otimes [0] - [1][0][01] + [1][0] \otimes [0][0][1] + [0][0][1] \otimes [0][1]) \\
+ & \left( -\frac{1}{2} \right) \left( -\frac{1}{2} \right) \left( [0] \otimes ([0][1] + [1][0][1]) + ([0][1] + [1][0][1]) \otimes [0]) \\
+ & \left( -\frac{1}{2} \right) \left( -\frac{1}{2} \right) \left( [1] \otimes ([1][0] + [0][1]) + ([1][0] + [0][1]) \otimes [0] \right).
\end{align}

The four first lines of the above equality correspond to the terms of Equation (29) in $N_1^X \otimes N_1^X \otimes 3 \otimes N_1^X \otimes 3 \otimes N_1^X$. The two last lines can be written (up to a 1/4 factor) as

\begin{align}
[0] \otimes ([0][1] + [1][0][1]) + ([0][1] + [1][0][1]) \otimes [0]
\end{align}

which is the beginning of of shuffle between terms in the $H^0$ of the bar construction. As an example,

\begin{align}
[0] \otimes ([0][1] + [1][0][1])
\end{align}
Now, one remarks that the case of $\sigma$-shuffle. The four other are extremely similar. Hence we will only discuss the $L$-"tree differential form" (that is using the elements $d_L$ and using the relations between $L$).

5.3. **Goncharov motivic coproduct.** In this subsection, we would like to illustrate how the differential equation satisfied by the elements $L^B_W$, written using its "tree differential form" (that is using the elements $L^B_W(1)$ instead of the elements $L^B_U$), gives another expression for Goncharov motivic coproduct.

Works of Levine [Lev11] and Spitzweck [Spi01] insure that the above differential coincides with Goncharov motivic coproduct for motivic iterated integrals (modulo products). We will not here review this theory but only recall some of the needed properties satisfied by Goncharov’s motivic iterated integrals [Gon05]. A short exposition of the combinatorics involved is also recalled in [GGL09, Section 8].
For our purpose, it is enough to consider motivic iterated integral as degree $n$ generating elements $I(a_0; a_1, \ldots, a_n; a_{n+1})$ of a Hopf algebra with $a_i$ in $A^1(\mathbb{Q})$. Their are subject to the following relations.

**Path composition:** for $x$ in $A^1(\mathbb{Q})$, one has

$$I(a_0; a_1, \ldots, a_n; a_{n+1}) = \sum_{k=0}^n I(a_0; a_1, \ldots, a_k; x)I(x; a_{k+1}, \ldots, a_n; a_{n+1}).$$

**Inversion:** which relates $I(a_0; a_1, \ldots, a_n; a_{n+1})$ with $I(a_{n+1}; a_n, \ldots, a_1; a_0)$

$$I(a_{n+1}; a_n, \ldots, a_1; a_0) = (-1)^n I(a_0; a_1, \ldots, a_n; a_{n+1}).$$

**Unit identity and neutral:**

$$I(a; b) = 1 \quad \text{and} \quad I(a_0; a_1, \ldots, a_n; a_0) = 0.$$

**Rescaling:** If $a_{n+1}$ and at least one of the $a_i$ is not zero then

$$I(0; a_1, \ldots, a_n, a_{n+1}) = I(0; a_1/a_{n+1}, \ldots, a_n/a_{n+1}, 1)$$

**Regularization:**

$$I(0, 1, 1) = I(0; 0; 1) = 0.$$

The product is given by the shuffle relations

$$I(a; a_1, \ldots, a_n; b)I(a; a_{n+1}, \ldots, a_{n+m}; b) = \sum_{\sigma \in Sh(n,m)} I(a; a_{\sigma(1)}, \ldots, a_{\sigma(n+m)}; b)$$

where $Sh(n, m)$ denotes the set of permutations preserving the order of the ordered subset $\{1, \ldots, n\}$ and $\{n+1, \ldots, n+m\}$. This motivic iterated integral corresponds formally to the iterated integral

$$\int_{\Delta_{a_0, a_{n+1}}} \frac{dt}{t - a_1} \wedge \cdots \wedge \frac{dt}{t - a_n}$$

with $\Delta_{a_0, a_{n+1}}$ the image of the standard simplex induced by a path from $a_0$ to $a_{n+1}$. The above relations reflect the relations satisfied by the integrals.

The coproduct is then given by the formula

$$\Delta^M \left( I(a_0; a_1, \ldots, a_n; a_{n+1}) \right) =$$

$$\sum_{\{a_{k_1}, \ldots, a_{k_r}\} \subset \{1, \ldots, n\}} \left( I(a_0; a_{k_1}, \ldots, a_{k_r}; a_{n+1}) \otimes \prod_{l=0}^r I(a_{k_l}; a_{k_{l+1}}, a_{k_{l+2}}, \ldots, a_{k_{l+1}-1}; a_{k_{l+1}}) \right)$$

with the convention that $k_0 = 0$ and $k_{r+1} = n + 1$.

Now, considering the reduced coproduct $\Delta^M = \Delta^M - (1 \otimes \text{id} + \text{id} \otimes 1)$ on the space of indecomposables (that is modulo products), the above formula reduces to

$$\Delta^M \left( I(a_0; a_1, \ldots, a_n; a_{n+1}) \right) =$$

$$\sum_{k \leq k+1 < l} \left( I(a_0; a_1, \ldots, a_k, a_{l+1}, \ldots, a_{n+1}; a_{n+1}) \otimes I(a_k; a_{k+1}, \ldots, a_{l-1}, a_l) \right).$$

This formula can be pictured placing the $a_i$ on a semicircle in the order dictated by their indices. Then a term in the above sums corresponds to a non trivial cords
between to vertices:

![Diagram of vertices and connections]

Considering the relation between multiple polylogarithms and iterated integrals, we want to relate our expression of the differential of $L^B_{011}$ at $t$ to the reduced coproduct for the motivic iterated integral $I(0; 0, x, x; 1)$ for $x = t^{-1}$. From the semicircle representation, one sees that there are five terms to consider:

However, the cord $c_1$ gives a zero term modulo products as $I(0; x; 1) = \frac{1}{2}I(0; x)I(0; x; 1)$ and cords $c_2$ and $c_3$ give terms equal to 0 using the regularization relations. Thus, there are only two terms to consider

$I(0; 0, x; 1) \otimes I(x; x; 1)$ and $I(0; x; 1) \otimes I(0, 0; x)$.

Using path composition, inversion and regularization relations, in the set of indecomposables elements, one has

$I(x; x; 1) = I(0; x; 1) + I(x; x; 0) = I(0; x; 1) - I(0; x; x) = I(0; x; 1) - I(0; 1; 1) = I(0; x; 1)$.

Thus the first term equals

$I(0; 0, x; 1) \otimes I(x; x; 1) = I(0; 0, x; 1) \otimes I(0; x; 1)$.

From rescaling relation, the second term equals

$I(0; x; 1) \otimes I(0; 0, 1; 1)$

and one can write modulo products

(32) $\Delta^M(I(0; 0, x, x; 1)) = I(0; 0, x; 1) \otimes I(0; x; 1) + I(0; x; 1) \otimes I(0; 0, 1; 1)$.

Keeping in mind that, for $x = t^{-1}$, $I(0; x; 1)$ corresponds to the fiber at $t$ of $L^B_1$ ($t \neq 1$) and that $I(0; 0, x; 1)$ corresponds to the fiber at $t$ of $L^B_{01}$ (any $t$), the above formula (32) correspond exactly to Equation (23):

$d_B(L^B_{011}) = (L^B_{01} - L^B_{01}(1)) \wedge L^B_1 = L^B_{01} \wedge L^B_1 + L^B_{01} \wedge L^B_{01}(1)$.

The fact that, as in the above example, Goncharov motivic iterated integrals corresponding to multiple polylogarithms in one variable, satisfy the tree differential equations (ED-T) is easily checked for Lyndon words with one 1; that is for the classical polylogarithms but can also be checked in higher length. It seems to be a general behavior. However, the above example and the example of $I(0; 0, 0, x, x; 1)$ corresponding to $L^B_{0011}$ below show that it involves using all the relations in order to pass from Goncharov formula to the shape of Equation (ED-T).
The case of \( \mathcal{L}^B_{0011} \) involves more computations but works essentially as the case of \( \mathcal{L}^B_{011} \). The reduced coproduct for \( I(0; 0, 0, x, x; 1) \) modulo products gives nine terms corresponding to the nine cords below:

The five dashed cords give terms equal to 0 for one of the following reasons: \( I(a; \ldots; a) = 0 \), regularization relations or shuffle relations. Hence we are left with four terms. The cords \( c_1 \) gives, using the rescaling relation,

\[
I(0; x; 1) \otimes I(0; 0, 0; 1) \quad \text{corresponding to } \mathcal{L}^B_0 \wedge \mathcal{L}^B_{001}(1).
\]

The cords \( c_2 \) gives a terms in

\[
I(0; 0, 0, x; 1) \otimes I(0; 0; x) \quad \text{corresponding to } \mathcal{L}^B_0 \wedge \mathcal{L}^B_{011}(1).
\]

Finally, \( \Delta^M(I(0; 0, 0, x; 1)) \) can be written as

\[
\Delta^M(I(0; 0, 0, x; 1)) = I(0; 0, 0, x; 1) \otimes I(0; 0; x) + I(0; 0, 0, x; 1) \otimes I(0; x; 1) + I(0; x; 1) \otimes I(0; 0, 0; 1) + I(0; x; 0) \otimes I(0; 0, 1; 1);
\]

expression which corresponds exactly to Equation (31):

\[
d_B(\mathcal{L}^B_{0011}) = \mathcal{L}^B_0 \wedge \mathcal{L}^B_{011} + (\mathcal{L}^B_{001} - \mathcal{L}^B_{001}(1)) \wedge \mathcal{L}^B_1 + \mathcal{L}^B_0 \wedge \mathcal{L}^B_{01}(1).
\]

6. Integrals and Multiple Zeta Values

We present here a sketch of how to associate an integral to cycles \( \mathcal{L}_{01}, \mathcal{L}^1_{01} \) and \( \mathcal{L}_{011} \). The author will directly follow the algorithm describe in [GGL09] [Section 9] and put in detailed practice in [GGL07]. Gangl, Goncharov and Levine construction seems to consist in setting particular choices of representatives in the intermediate Jacobians for their algebraic cycles.

The author does not have yet a good enough general understanding of this Hodge realization. That is why computations below are only outlined. In particular, the lack of precise knowledge of the “algebraico-topological cycle algebra” described in [GGL09] makes it difficult to control how “negligible” cycles are killed looking at the \( H^0 \) of its bar construction.
6.1. An integral associated to $L_{01}$ and $L_{01}^1$. We recall the parametrized cycle expression for $L_{01}$:

$$L_{01} = [t; 1 - \frac{t}{x_1}, x_1, 1 - x_1] \quad \subset X \times \Box^3.$$  

One wants to bound $L_{01}$ by an algebraic-topological cycle in a larger bar construction (not described here) introducing topological variables $s_i$ in real simplices

$$\Delta^n_s = \{0 \leq s_1 \leq \cdots \leq s_n \leq 1\}.$$ 

Let $d^s : \Delta^n_s \rightarrow \Delta^{n-1}_s$ denotes the simplicial differential

$$d^s = \sum_{k=0}^n (-1)^k i_k^s$$

where $i_k : \Delta^{n-1}_s \rightarrow \Delta^n_s$ is given by the face $s_k = s_{k+1}$ in $\Delta^n_s$ with the usual conventions for $k = 0, n$.

Defining

$$C^{s,1}_{01} = [t; 1 - \frac{s_3 t}{x_1}, x_1, 1 - x_1]$$

for $s_3$ going from 0 to 1, one sees that $d^s(C^{s,1}_{01}) = L_{01}$ as $s_3 = 0$ implies that the first cubical coordinate is 1. The algebraic boundary $\partial$ of $C^{s,1}_{01}$ is given by the intersection with the faces of $\Box^3$:

$$\partial(C^{s,1}_{01}) = [t; s_2 t, 1 - s_2 t] \quad \subset X \times \Box^2.$$ 

This cycle is part of the boundary of a larger “simplicial” algebraic cycle

$$C^{s,2}_{01} = [t; s_2 t, 1 - s_1 t].$$

Computing the simplicial differential of $C^{s,2}_{01}$ gives

$$d^s(C^{s,2}_{01}) = [t; s_2 t, 1 - s_2 t] - [t; t, 1 - s_1 t] \quad \subset X \times \Box^2$$

with $0 \leq s_2 \leq 1$ on the first term and $0 \leq s_1 \leq 1$ on the second term.

Note that the cycle $[t; t, 1 - s_1 t]$ is negligible as it is a product

$$[t; t, 1 - s_1 t] = L_0[t; 1 - s_1 t]$$

and thus can be cancel is the bar construction setting as the multiplicative boundary of

$$-|L_0|[t, 1 - s_1 t].$$

Thus, up to negligible terms,

$$(d^s + \partial)(C^{s,1}_{01} + C^{s,2}_{01}) = L_{01}.$$ 

Now, we fix the situation at the fiber $t_0$ and following Gangl, Goncharov and Levin, we associate to the algebraic cycle $L_{01}|_{t=t_0}$ the integral $I_{01}(t_0)$ of the standard volume form

$$\frac{1}{(2\pi)^2} \frac{dz_1 dz_2}{z_1 z_2}$$

over the simplex given by $C^{s,2}_{01}$. That is:

$$I_{01}(t_0) = -\frac{1}{(2\pi)^2} \int_{0 \leq s_1 \leq s_2 \leq 1} \frac{ds_2}{s_2} \wedge \frac{t_0 ds_1}{1 - t_0 s_2}$$

$$= \frac{1}{(2\pi)^2} \int_{0 \leq s_1 \leq s_2 \leq 1} \frac{ds_1}{s_2} \wedge \frac{ds_2}{1 - s_1} = \frac{1}{(2\pi)^2} I_{01}^{\text{low}}(t_0).$$

In particular, this expression is valid for $t_0 = 1$, as is the cycle $L_{01}|_{t=1}$, and gives $1/(2\pi^2)\zeta(1).$

Before presenting the weight 3 example of $L_{011}$, we describe shortly below the situation for $L_{01}^1$. In the bar construction the element $L_{01}^1$ is equal to the difference

$\text{Low Weight Multiple Zeta Values Cycles.}$  

$37$
Let $L^B_{01} - L^H_{01}$ (1). Associating an integral to $L^1_{01}$ works in the same way as the cycle $L_{01}$ but it also reflects the correspondence with $L^B_{01} - L^H_{01}$ (1).

The expression of $L^1_{01}$ in terms of parametrized cycle is given by

$$L^1_{01} = [t; \frac{x_1 - t}{x_1 - 1}, x_1, 1 - x_1]$$

and can be bounded using the “simplicial” algebraic cycle

$$C^s_{01} = -[t; \frac{x_1 - s_2 t}{x_1 - s_2}, x_1, 1 - x_1].$$

Now, the algebraic boundary of $C^s_{01}$ gives two terms

$$\partial(C^s_{01}) = [-t; s_2 t, 1 - s_2 t] + [t; s_2, 1 - s_2].$$

Then, one defines $C^{s,2}_{01}$ for simplicial variable $0 \leq s_1 \leq s_2 \leq 1$ as

$$C^{s,2}_{01} = -[t; s_2 t, 1 - s_1 t] + [t; s_2, 1 - s_1]$$

which simplicial boundary cancels $\partial(C^s_{01})$ up to negligible cycles. Again, fixing a fiber $t_0$ the integral associated to $L^1_{01}|_{t=t_0}$ is the integral of the standard volume form over the $C^{s,2}_{01}$,

$$I_{01}^{s,2}(t_0) = \frac{1}{(2\pi)^2} \int_{0 \leq s_1, s_2 \leq 1} \frac{ds_2}{s_2} \wedge \frac{t_0 ds_1}{1 - t_0 s_1} + \frac{1}{(2\pi)^2} \int_{0 \leq s_1, s_2 \leq 1} \frac{ds_2}{s_2} \wedge \frac{ds_1}{1 - s_1}.$$

This expression is exactly the difference

$$I_{01}^{s,2}(t_0) = \frac{1}{(2\pi)^2} (L^{c,2}_2(t_0) - L^{c,2}_2(1)).$$

6.2. An integral associated to $L_{01}$. Let’s recall the expression of $L_{01}$ as parametrized cycle:

$$L_{01} = [-t; 1 - \frac{t}{x_2}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1].$$

As previously, one wants to bound $L_{01}$ by an algebraic-topological cycle. Hence we define

$$C^{s,1}_{01} = [t; 1 - \frac{s_3 t}{x_2}, 1 - x_2, \frac{x_1 - x_2}{x_1 - 1}, x_1, 1 - x_1]$$

for $s_3$ going from 0 to 1. Then, $d^a(C^{s,1}_{01}) = L_{01}$ as $s_3 = 0$ implies that the first cubical coordinate is 1.

Now the algebraic boundary $\partial$ of $C^{s,1}_{01}$ is given by the intersection with the codimension 1 faces of $\square^5$

$$\partial(C^{s,1}_{01}) = [t; 1 - s_3 t, \frac{x_1 - s_3 t}{x_1 - 1}, x_1, 1 - x_1].$$

We can again bound this cycle by introducing a new simplicial variable $0 \leq s_2 \leq s_3$ and the cycle

$$C^{s,2}_{01} = [t; 1 - s_3 t, \frac{x_1 - s_2 t}{x_1 - s_2 / s_3}, x_1, 1 - x_1].$$

The intersections with the face of the simplex $\{0 \leq s_2 \leq s_3 \leq 1\}$ given by $s_2 = 0$ leads to empty cycles (as at least one cubical coordinates equals 1) while the intersection with face $s_3 = 1$ leads to a “negligible” cycle. Thus, the simplicial boundary of $C^{s,2}_{01}$ satisfies (up to a negligible term)

$$d^a(C^{s,2}_{01}) = -\partial(C^{s,1}_{01}) = [-t; 1 - s_3 t, \frac{x_1 - s_3 t}{x_1 - 1}, x_1, 1 - x_1].$$

Its algebraic boundary is given by

$$\partial(C^{s,2}_{01}) = [-t; 1 - s_3 t, s_2 t, 1 - s_2 t] + [t; 1 - s_3 t, \frac{s_2}{s_3}, 1 - \frac{s_2}{s_3}].$$
Finally, we introduce a last simplicial variable $0 \leq s_1 \leq s_2$ and a purely topological cycle
\[ C_{011}^{s_3} = -[t; 1 - s_3 t, s_2 t, 1 - s_1 t] + [t; 1 - s_3 t, \frac{s_2}{s_3}, 1 - \frac{s_1}{s_3}] \]
whose simplicial differential is (up to negligible terms) given by the face $s_1 = s_2$:
\[ d^1(C_{011}^{s_3}) = -\partial(C_{011}^{s_2}) = [t; 1 - s_3 t, s_2 t, 1 - s_2 t] - [t; 1 - s_3 t, \frac{s_2}{s_3}, 1 - \frac{s_2}{s_3}] \]
and whose algebraic boundary is 0 (up to negligible terms).

Finally one has
\[ (d^1 + \partial)(C_{011}^{s_1} + C_{011}^{s_3} + C_{011}^{s_3}) = L_{011} \]
up to negligible terms.

Now, we fix the situation at the fiber $t_0$ and following Gangl, Goncharov and Levin, we associate to the algebraic cycle $L_{011}|_{t=t_0}$ the integral $I_{011}(t_0)$ of the standard volume form
\[ \frac{1}{(2\pi i)^3} dz_1 dz_2 dz_3 \]
over the simplex given by $C_{011}^{s_3}$. That is :
\[ I_{011}(t_0) = -\frac{1}{(2\pi i)^3} \int_{0 \leq s_1 \leq s_2 \leq s_3 \leq 1} \frac{t_0 ds_3}{1 - t_0 s_3} \land \frac{ds_2}{s_2} \land \frac{ds_1}{1 - t_0 s_1} + \frac{1}{(2\pi i)^3} \int_{0 \leq s_1 \leq 1} t_0 ds_3 \int_{0 \leq s_2 \leq s_3 \leq 1} \frac{ds_2}{s_2} \land \frac{ds_3}{s_3 - 1} \frac{ds_3}{s_3} \]
Taking care of the change of sign due to the numbering, the first term in the above sum is (for $t_0 \neq 0$) and up to the factor $(2\pi i)^{-3}$ equal to
\[ L_{1,2}^{C}(t_0) = \int_{0 \leq s_1 \leq s_2 \leq s_3 \leq 1} \frac{ds_3}{s_3} \land \frac{ds_2}{s_2} \land \frac{ds_3}{s_3 - 1} \]
while the second term equals (up to the same multiplicative factor)
\[-L_{1,1}^{C}(t_0) L_{2}^{C}(1) \]

Globally the integral is well defined for $t_0 = 0$ and, which is the interesting part, also for $t_0 = 1$ as the divergencies as $t_0$ goes to 1 cancel each other in the above sums. A simple computation and the shuffle relation for $L_{1,2}^{C}(t_0) L_{2}^{C}(t_0)$ shows that the integral associated to the fiber of $L_{011}$ at $t_0 = 1$ is
\[ (2\pi i)^3 I_{011}(1) = -2 L_{2,1}^{C}(1) = -2 \zeta(2,1) \]
