3-TORSION AND CONDUCTOR OF GENUS 2 CURVES

TIM DOKCHITSER AND CHRISTOPHER DORIS

Abstract. We give an algorithm to compute the conductor for curves of genus 2. It is based on the analysis of 3-torsion of the Jacobian for genus 2 curves over 2-adic fields.

1. Introduction

One of the main arithmetic invariants of a curve $C/\mathbb{Q}$ (or over a number field) is its conductor. It is a representation-theoretic quantity measuring the arithmetic complexity of $C$, and it is particularly important in the considerations that involve Galois representations or $L$-functions of curves.

In practice, the conductor is difficult to compute. It is defined as a product $N = \prod p^{n_p}$ over primes $p$, so the problem is computing the local conductor exponents $n_p$; these are functions of $C/\mathbb{Q}_p$. For elliptic curves (genus 1), the problem of computing $n_p$ is solved with Tate’s algorithm [31] and Ogg-Saito formula [25, 28]. In genus 2 and $p \neq 2$ there is an algorithm of Liu [22] via the Namikawa–Ueno classification [24], and for hyperelliptic curves of arbitrary genus there is a formula for the conductor [9], again for $p \neq 2$.

As the global conductor $N$ requires the knowledge of $n_p$ for all primes $p$, including $p = 2$, it is currently only provably computable for elliptic curves, and for quotients of modular curves using modular methods (see e.g. [14]).

In this paper, we propose an (unconditional) algorithm to compute the conductor for curves of genus 2. The case to consider is $p = 2$, so from now on $C$ will be a non-singular projective curve of genus 2, defined over a finite extension $K$ of $\mathbb{Q}_2$. Recall that the conductor exponent is the sum of the tame and wild parts (see [9]),

$$n_2 = n = n_{\text{tame}} + n_{\text{wild}}.$$

The difficult one is the wild part, which is the Swan conductor of the $l$-adic Tate module of the Jacobian $J/K$ of $C/K$, for any $l \neq 2$. We will take $l = 3$ and use that $n_{\text{wild}}$ can be computed from the action of $\text{Gal}(K/K)$ on the 3-torsion $J[3]$. The equations defining $J[3]$ as a scheme are well-known.

2000 Mathematics Subject Classification. 11G20 (Primary); 14D10, 11F80, 11G30.

Key words and phrases. Conductor, hyperelliptic curves, 3-torsion, local fields.
in genus 2 (see §1.1 or [3]) and we use Grobner basis machinery to convert them essentially to a univariate equation of degree $80 = |J[3] \setminus \{0\}|$. The problem then becomes to compute the Galois group of this polynomial, and enough information about the inertia action on the roots to reconstruct the conductor. This is the core of the paper (§4). In particular, we discuss how to guarantee that the results are provably correct (§4.3).

As for the tame part, it can be computed from the regular model of $C/K$, which is in principle accessible: take any model of $C$ over the ring of integers of $K$, and perform repeated blowups until it becomes regular. However, the algorithm to compute a regular model is currently only partially implemented in Magma [2], and so we complement our algorithm with a result that determines $n_{\text{tame}}$ from elementary invariants, in the majority of the cases (Theorem 3.2).

An alternative approach to getting the conductor would be to find a Galois extension $F/K$ where $C$ acquires semistable reduction and a semistable model over $F$, and analyse the action of inertia of $F/K$ on the model. From this one can determine the $l$-adic representation $V_l J$, in particular the conductor exponent; see e.g. [5, §6]. Moreover, that there are more compact polynomials defining such an $F$ in the case of genus 2, $p = 2$ than the degree $80$ 3-torsion polynomial. For example, there is the monodromy polynomial of Lehr-Matignon in the potentially good reduction case, of degree 16 [20, §3]. However, the splitting field of any such polynomial would have ramification degree no less that that of $K(J[3])/K$, by the Serre-Tate theorem [30, Cor. 2]. So such a field (and the model of $C$ over it) would be still prohibitively large to compute, and our algorithm avoids this.

We end by noting that the core of the paper is a special test case of a general algorithm (in progress) to find Galois groups over local fields [11]. Regarding Groebner bases, the algorithm would be accelerated by an algorithm to solve multivariate systems of equations $p$-adically (see Remark 5.1). This is also work in progress. Finally, it should be possible to extend the algorithm to compute the conductor to function fields of characteristic 2 as well, by modifying the equations of the curve and its 3-torsion in §4.1 appropriately.

This algorithm has been implemented as a Magma package [13], and has been used to verify most of the genus 2 curves in the LMFDB (§6).

Acknowledgements. This research is partially supported by an EPSRC grant EP/M016838/1 ‘Arithmetic of hyperelliptic curves’ and by GCHQ. We would like to thank David Roberts for helpful discussions and the referees for their suggestions.

\footnote{Then $n_{\text{tame}} = 4 - 2d_a - d_t$, where $d_a$ (‘abelian part’) is the sum of genera of reduced components of the special fibre of the model, and $d_t$ (‘toric part’) is the number of loops}
2. Notation

Throughout the paper, we use the following notation:

- $K, L, \ldots$ local fields, of residue characteristic $p$
- $\mathcal{K}, \mathcal{L}, \ldots$ global fields
- $G_K = \text{Gal}(\overline{K}/K)$, the absolute Galois group of $K$
- $I_K < G_K$ its inertia group
- $T$ $\mathbb{Z}_l$-module with an action of $G_K$, with $l \neq p$
- $V$ the associated $l$-adic representation $T \otimes_{\mathbb{Z}_l} \mathbb{Q}_l$
- $\bar{V}$ the reduction $T \otimes_{\mathbb{Z}_l} \mathbb{F}_l$
- $G^u$ upper numbering of ramification groups
- $G_v$ lower numbering of ramification groups
- $n = n_{\text{tame}} + n_{\text{wild}}$ conductor exponent

We are interested in the situation that $J/K$ is an abelian variety, $T = T_lJ$ is its $l$-adic Tate module, $V = V_lJ$ and $\bar{V} = J[\ell]$ is its $l$-torsion. Recall that the conductor exponent of such a representation is given by (see e.g. [32])

$$n(V) = \int_{-1}^{\infty} \text{codim} V^{G^K} du,$$

with

$$n_{\text{tame}}(V) = \int_{-1}^{0} \quad \text{and} \quad n_{\text{wild}}(V) = \int_{0}^{\infty}.$$

For $u > 0$, $G^K$ is pro-$p$, and [32, §6]

$$\text{codim} V^{G^K} = \text{codim} \bar{V}^{G^K}.$$

Our approach is that we will compute $n_{\text{tame}}(V)$ as the codimension of inertia invariants $V^{I_K}$, and the wild conductor exponent as

$$n_{\text{wild}}(V) = \int_{0}^{\infty} \text{codim} J[\ell]^{G^K} du,$$

and replacing $G_K$ by $\text{Gal}(K(J[\ell])/K)$.

3. Tame Conductor Exponent

Let $K$ be any non-Archimedean local field, $J/K$ a $g$-dimensional abelian variety, and $l$ a prime different from the residue characteristic of $K$. Write $T = T_lJ$ for the $l$-adic Tate module of $J/K$ and $V = V_lJ = T_lJ \otimes_{\mathbb{Z}_l} \mathbb{Q}_l$, both viewed as representations of the inertia group $I_K < G_K$.

Recall that there is a canonical filtration on $T$ coming from the toric part and the abelian part of $J$ over a field where it acquires semistable reduction.

---

2These are ‘standard’ facts that we found a little hard to locate in the literature, but they are summarised in [4] §2.10: for the existence of a $\text{Gal}(\overline{K}/K)$-stable filtration that forces the Galois group action to be upper-triangular see [4] p.13, 2nd half; for the fact that the representations on the graded pieces $\chi$ and $\rho$ are independent of $l$ see [4] p.13, bottom], and for the maps between them and the monodromy pairing [4 pp. 12,14]. See also forthcoming paper [10].
With respect to this filtration, $I_K$ acts on $T$ as

$$
\begin{pmatrix}
\chi & N \\
0 & \rho & \ast \\
0 & 0 & \hat{\chi}
\end{pmatrix}
$$

with $\chi : I_K \to \text{GL}_t(\mathbb{Z}_l)$, $\rho : I_K \to \text{GL}_{2a}(\mathbb{Z}_l)$ continuous with finite image (t='toric', a='abelian', $2t + 2a = \text{rk}_{\mathbb{Z}/l}T = 2g$), and $\hat{\chi}$ the dual of $\chi$. The 'monodromy matrix' $N$ has $\mathbb{Z}$-coefficients, and $\chi$ factors through $\text{GL}_t(\mathbb{Z})$ as well. In particular, $\chi \otimes \mathbb{Q}_l$ is self-dual with determinant of order 1 or 2. Consequently, the same holds for $\rho \otimes \mathbb{Q}_l$, as $\det (3.1) = 1$ by the Weil pairing.

Now, we specialise to the case when $J = \text{Jac} C$ is the Jacobian of a genus 2 curve and $l = 3$. We will explain in §4 how to compute the image $I$ of $I_K$ in $\text{Aut} J[3]$ and the dimension of inertia invariants $\dim J[3]^I$. We can also compute $t$ and $a$ using a theorem of Liu [21, Thm 1] that determines the stable type of $C/K$ from the Igusa invariants of the curve. There are 7 possible stable types in genus 2, in other words possibilities for stable reduction. (For elliptic curves there are 2 types of stable reduction — good and multiplicative.) They are listed as cases I, II, ..., VII in Liu’s theorem, and in the notation of [7] they are denoted 2, $1_n$, $1_{n,m}$, $U_{n,m,r}$, $1 \times 1$, $1 \times I_n$, $I_n \times I_m$. The special fibres are as follows, with numbers above the components indicating geometric genus:

![Figure 1. The 7 stable reduction types for genus 2.](image)

Of these, types 2 and $1 \times 1$ have $t = 0, a = 2$ (potentially good reduction of $J$), types $1_n$ and $1 \times I_n$ have $t = a = 1$ (mixed), and $I_{n,m}$, $U_{n,m,r}$ and $I_n \times I_m$ have $t = 2, a = 0$ (potentially totally toric reduction).

The main result of this section recovers the tame conductor exponent of $J/K$ from the invariants $I$, $\dim J[3]^I$ and $t$, when this is possible:

**Theorem 3.2.** Let $K$ be a non-Archimedean local field of residue characteristic $\neq 3$ and $C/K$ a genus 2 curve with Jacobian $J/K$. Write

- $I =$ image of inertia $I_K < G_K$ in $\text{Aut} J[3]$ (so $I < \text{Sp}_4(\mathbb{F}_3)$),
- $d = \dim (V_3J)^I$ (so $0 \leq d \leq 4$),
- $\bar{d} = \dim J[3]^I$ (so $0 \leq \bar{d} \leq 4$),
- $t =$ potential toric dimension of $J$ (so $0 \leq t \leq 2$),
- $f = 4 - d = n_{tame}(V_3J) = n_{tame}(J/K)$ (so $0 \leq f \leq 4$).
Then \( \bar{d} \geq d \) and so \( f \geq 4 - \bar{d} \). Moreover,

1. If \( \bar{d} = 0 \) then \( f = 4 \).
2. If \( \bar{d} = 4 \) then \( d = 4 - t \) and \( f = t \).
3. Suppose \( J \) has potentially good reduction \( (t=0) \). If \( |I| = 3 \) and \( \bar{d} = 2 \) then \( f = 4 \); in all other cases, \( f \) is the smallest even integer \( \geq 4 - \bar{d} \).
4. If \( (t,|I|) \in \{(1,3),(2,3),(1,2),(1,6)\} \) then \( f \) is not uniquely determined as a function of \( t \), \( I \) and \( \bar{d} \).
5. If \( (t,|I|) = (2,9) \) then \( f = 4 \); in all other cases not covered, \( f = 3 \).

**Proof.** Write \( T = T_3J, V = V_3J \). Note that after tensoring \((3.1)\) with \( \mathbb{Q}_3 \) and a suitable change of basis, both \( * \)'s can be made 0 and \( N \) a \( t \times t \) identity matrix. In particular,

\[
V^{I_K} = \chi^I \oplus \rho^I, \quad f = 4 - \dim \chi^I - \dim \rho^I.
\]

If \( V \) has an \( I_K \)-invariant subspace of dimension \( d \), its intersection with \( T \) gives a rank \( d \) saturated sublattice of \( T \), whose reduction contributes at least dimension \( d \) to \( J[3]^I \). This shows that \( \bar{d} \geq d \), and implies (1).

(2) By Raynaud’s semistability criterion [16, Prop 4.7], \( J \) is semistable if \( J[m] \) is unramified for some \( m \geq 3 \) coprime to the residue characteristic. Here \( I_K \) acts trivially on \( J[3] \), and so \( J \) is semistable. In other words, \( f = t \) and \( \bar{d} = 4 - t \).

For the remainder of the proof, we assume \( \bar{d} \in \{1,2,3\} \).

(3) By Serre-Tate’s theorem [30, Cor. 2], \( J \) has good reduction over \( K(J[3]) \); that is, \( I_K \) acts on \( V_3J \) through \( I \). By Poincare duality, this representation has even-dimensional inertia invariants, in other words \( d \) is even. As \( d \leq \bar{d} \in \{1,2,3\} \), the only possibility for \( f = 4 - d \) not to be the smallest even integer \( \geq 4 - \bar{d} \) is when \( d = 0 \) and \( \bar{d} \in \{2,3\} \). Suppose we are in that case.

Consider the possibilities for \( I \prec \text{Sp}_4(\mathbb{F}_3) \). Note that 3 divides \( |I| \), for otherwise the classical representation theory of \( I \) agrees with its modular representation over \( \mathbb{F}_3 \), implying \( d = \bar{d} \). Also note that \( C_3 \times C_3 \) is not a quotient of \( I \), as the residue characteristic of \( K \) is not 3, and tame inertia is cyclic. Computing in Magma [2], we find that \( \text{Sp}_4(\mathbb{F}_3) \) has 162 conjugacy classes of subgroups, of which 5 satisfy the three properties (a) order multiple of 3, (b) no \( C_3 \times C_3 \)-quotient, and (c) \( \bar{d} \in \{2,3\} \). Call them \( H_1, H_2, H_3 \cong C_3, H_4 \cong C_6 \) and \( H_5 \cong \text{SL}_2(\mathbb{F}_3) \).

By the classification of integral \( C_3 \)-lattices [5, 27], there are two indecomposable \( \mathbb{Z}_3[C_3] \)-lattices, up to isomorphism: the trivial lattice of rank 1, and a lattice \( \Lambda \) of rank 2 on which the generator of \( C_3 \) acts as \( \left( \begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix} \right) \); every finite rank \( \mathbb{Z}_3[C_3] \)-lattice is a direct sum of these. If \( I \cong C_3 \), then as \( d = 0 \), we must have \( T \cong \Lambda \oplus \Lambda \), and it has \( \bar{d} = 2 \) as claimed.

It remains to show that \( I \in \{H_4, H_5\} \) with \( d = 0 \) is impossible. Suppose we are in this case, and let \( z \in I \) be the unique central element of order 2. As above, the classical representation theory of the group \( \langle z \rangle \cong C_2 \) agrees with its modular representation over \( \mathbb{F}_3 \). In both \( H_4 \) and \( H_5 \) the action of
z on $\tilde{V} = J[3]$ has two $+1$ and two $-1$ eigenvalues. The same is therefore true for $V$; moreover, $V = V^+ \oplus V^-$ and $T = T^+ \oplus T^-$ decompose into the two 2-dimensional eigenspaces for $z$ and this decomposition induces the one on $J[3]$.

The group $\text{SL}_2(\mathbb{F}_3)$ has 3 one-dimensional complex representations factoring through $\text{SL}_2(\mathbb{F}_3)/\mathbb{Q}_8 \cong C_3$, three faithful 2-dimensional ones in which $z$ acts as $-1$, and a 3-dimensional one with $z$ acting as $+1$. Thus, when $I$ is $H_4$ and $H_5$, the space $T^+$ must be a representation of the unique $C_3$ quotient of $I$. It has no trivial subrepresentations (as $d = 0$), so $T^+ \cong \Lambda$ as a $\mathbb{Z}_3[C_3]$-module. But then

$$\bar{d} = \dim(\Lambda \otimes \mathbb{F}_3)^{C_3} + \dim(T^- \otimes \mathbb{F}_3)^I = 1 + 0,$$

contradicting the assumption $\bar{d} \in \{2, 3\}$.

(4) The following curves give examples over $\mathbb{Q}_2$ that prove that $f$ is not a function of $t$, $I$ and $\bar{d}$, as claimed. (In each case, $f$ can be determined by computing the regular model.)

| $t$ | $I$ | $\bar{d}$ | $f$ | $\text{C}/\mathbb{Q}_2$ |
|-----|-----|---------|-----|-----------------|
| 1   | $C_3$ | 3       | 1   | $y^2 = x^6 + 4x^4 + 2x^2 + 4x^2 + 1$ |
| 1   | $C_3$ | 3       | 3   | $y^2 = 4x^6 - 20x^4 - 8x^3 + 21x^2 + 22x + 13$ |
| 2   | $C_3$ | 2       | 2   | $y^2 = x^6 + 6x^4 - 7x^2 + 16$ |
| 2   | $C_3$ | 2       | 4   | $y^2 = 5x^6 + 4x^3 - 12$ |
| 1   | $C_2$ | 2       | 2   | $y^2 = -x^6 + 6x^4 - x^2 - 8$ |
| 1   | $C_2$ | 2       | 3   | $y^2 = x^6 - 6x^4 + x^2 + 8$ |
| 1   | $C_6$ | 1       | 3   | $y^2 = x^6 - 6x^4 + 5x^2 + 8$ |
| 1   | $C_6$ | 1       | 4   | $y^2 = x^6 - 31x^4 - 25x^2 - 32$ |

(5) To deal with all the remaining cases, first suppose that $J$ has totally toric reduction over $K(J[3])$, in other words $t = 2$. In the notation of (3.1), we have a homomorphism

$$\chi : I \longrightarrow \text{GL}_2(\mathbb{Z}) \quad (\hookrightarrow \text{GL}_2(\mathbb{Z}_3))$$

whose image we denote by $\bar{I}$ and whose kernel is $C_1$ or $C_3$. Finite subgroups of $\text{GL}_2(\mathbb{Z})$ are contained in $D_4$ or $D_6$. Of those, $D_3$, $D_6$ only occur as inertia groups in residue characteristic 3, and $C_2^2$, $C_4$, $C_6$, $D_4$ have an element acting as $-1$, forcing $\bar{d} = 0$ (case (1)). The remaining possibilities are

$$\bar{I} \in \{C_1, C_2, C_3\}, \quad I \in \{C_1, C_2, C_3, C_6, C_9\}.$$ 

We have excluded $I = C_1$ (case (1)) and $I = C_3$ (case (4)). When $I = C_9$, its image $\bar{I} \cong C_3$ has no invariants, and so $f = 4$ (proving the case $(t, |I|) = (2, 9)$). The only remaining case is $\bar{I} = C_2$, acting with eigenvalues $+1, -1$ (otherwise $\bar{d} \in \{0, 4\}$ again). In this case, the full action on $T$ is of the form

\[
\begin{pmatrix}
1 & 0 & * & 0 \\
0 & -1 & 0 & * \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1 \\
\end{pmatrix}
\]
in some basis, with non-zero *'s. This has one-dimensional invariants, and so \( f = 3 \), as claimed.

Finally suppose \( t = 1 \), so that \( I_K \) acts on \( T \) as

\[
\begin{pmatrix}
\chi & * & * \\
0 & a & b \\
0 & c & d \\
0 & 0 & 0
\end{pmatrix}
\]

As before, write \( \rho \) for the representation \( I_K \rightarrow (a \ c \ b \ d) \). Because \( I \) is not one of the already excluded groups \( C_1, C_2, C_3, C_6 \), the image of \( I_K \) under \( \bar{\rho} = \rho \mod 3 \) is not \( C_1 \) or \( C_2 \). But any other subgroup of \( \text{GL}_2(\mathbb{Z}_3) \) of finite order is either \( D_3 \), which cannot be a local Galois group, or \( \bar{\rho}(I) \) has no invariants on \( F^2_3 \). Hence \( \bar{\rho} I_K = 0 \), and \( J[3] I_K = \chi I_K \) has either dimension 0 (case (1)) or dimension 1 with \( f = 3 \), as claimed. \( \square \)

4. WILD CONDUCTOR EXPONENT

Recall that we wish to compute

\[
n_{\text{wild}} = \int_0^\infty \text{codim} J[3]^G u \, du
\]

where \( G = G_K \). Note, however, that \( G_K \) acts on \( J[3] \) through its finite quotient \( \text{Gal}(K(J[3])/K) \) so we may equally well take \( G = \text{Gal}(K(J[3])/K) \) or any quotient in between.

The integrand here is decreasing, non-negative, integral and left-constant, so if we denote by \( u_1 = 0, u_2, \ldots, u_t \) the jump points in the integrand, then we get

\[
n_{\text{wild}} = \sum_{i=2}^t (u_i - u_{i-1}) \text{codim} J[3]^{G_{u_i}}.
\]

Let \( Z \in J[3] \) be a 3-torsion point and let \( L = K(Z) \) be the extension it generates. Then \( Z \) is fixed by \( G^u \) if and only if \( L \) is fixed by \( G^u \). Since \( G^u \triangleleft G \), this occurs if and only if any \( K \)-conjugate of \( Z \) is fixed by \( G^u \). If \( \hat{u} = \hat{u}(L/K) = \inf \{ u : L \text{ fixed by } G^u \} \) denotes the highest upper ramification break of \( L/K \), then this occurs if and only if \( \hat{u} \leq u \).

Hence, if \( Z_1, \ldots, Z_m \) are representatives of the \( K \)-conjugacy classes of \( J[3] \), generating extensions \( L_i/K \) with highest upper ramification break \( \hat{u}_i \) then letting \( u_0 = -1 < u_1 = 0 < \ldots < u_t \) be the sorted elements of \( \{-1, 0, u_1, \ldots, \hat{u}_m\} \) we deduce

\[
n_{\text{wild}} = \sum_{i=2}^t (u_i - u_{i-1}) \left( 2g - \log_3 \sum_{j: \hat{u}_j \leq u_i} (L_j : K) \right)
\]

since \( 2g = \dim V \) and \( (L_j : K) \) is the number of \( K \)-conjugates of \( Z_j \).

We proceed by finding the extensions \( L_i/K \) explicitly, from which we compute \( n_{\text{wild}} \) via this equation.
4.1. **Equation for 3-torsion of genus 2 curves.** As before, let $C/K$ be a curve of genus 2, with Jacobian $J$. The linear system for the canonical divisor on $C$ yields a standard model

$$C : y^2 = f(x), \quad \deg f = 5 \text{ or } 6.$$ 

The following statement is well-known (see e.g. [3] proof of Lemma 3); in fact, it works over any field of characteristic $\neq 2, 3$.

**Proposition 4.1.** Non-zero elements of $J[3]$ are in 1-1 correspondence with ways of expressing $f$ in the form

$$f = (z_4 x^3 + z_3 x^2 + z_2 x + z_1)^2 - z_7 (x^2 + z_6 x + z_5)^3, \quad z_i \in \bar{K}, \quad (*)$$

and this correspondence preserves the action of $G_K$.

Explicitly, suppose $D$ is a divisor on $C$,

$$D = (P_1) + (P_2) - (\infty_1) - (\infty_2), \quad P_i = (X_i, Y_i)$$

for which $3D$ is principal, say $3D = \text{div} \ g$. Then $g \in \langle 1, x, x^2, x^3, y \rangle$. After a (unique) re-scaling, say

$$g = y + b_3 x^3 + b_2 x^2 + b_1 x + b_0.$$ 

The norm

$$\text{Norm}_{K(C)/K(x)}(g) = (b_3 x^3 + b_2 x^2 + b_1 x + b_0 - y)(b_3 x^3 + b_2 x^2 + b_1 x + b_0 + y)$$

is a function on $\mathbb{P}^1$ whose divisor $3(X_1) + 3(X_2) - 6(\infty)$ is a cube, and so

$$(b_3 x^3 + b_2 x^2 + b_1 x + b_0)^2 - f = c_2(x^2 + c_1 x + c_0)^3,$$

as stated. In this form, 

$$X_{1,2} = \text{roots of } x^2 + c_1 x + c_0 = 0, \quad Y_i = -b_3 X_i^3 - b_2 X_i^2 - b_1 X_i - b_0.$$ 

We view $(*)$ as giving a system of 7 equations in the 7 variables $z_i$.

4.2. **Finding the 3-torsion fields.** Our goal, then, is to find the ($K$-isomorphism classes of) fields $L/K$ generated by the ($K$-conjugacy classes of) solutions $Z$ to the system of equations $(*)$.

A general tool used to solve systems of polynomial equations such as this is to compute a Groebner basis for the polynomial ideal generated by the polynomials. Generically, a reduced sorted minimal Groebner basis with respect to the lexicographic ordering on variables will be a finite sequence of polynomials such that the first is univariate, the second is a polynomial in two variables, and so on. Then to solve the system, we first find a root of the first polynomial; then we substitute this value into the second polynomial, yielding a polynomial in one variable, and we find a root of this; we repeat this procedure. In the end, this will produce a sequence of roots which together are a solution to the system.

For our system in particular, the 80 roots come in pairs of the form

$$(Z_1, Z_2, Z_3, Z_4, Z_5, Z_6, Z_7), \quad (-Z_1, -Z_2, -Z_3, -Z_4, Z_5, Z_6, Z_7),$$
and so generically there are 40 distinct values for $Z_7$, for each of these there is a unique value for $Z_6$ and $Z_5$ and two distinct values for $Z_4$, and for each of these there is a unique value for $Z_3$, $Z_2$ and $Z_1$.

In this generic case, the Groebner basis described above will be a sequence of 7 polynomials $B_1, \ldots, B_7 \in \mathbb{K}[z_1, \ldots, z_7]$ such that $B_i \in \mathbb{K}[z_i, \ldots, z_7]$, deg $z_i B_i = d_i$ where $d = (1, 1, 1, 2, 1, 1, 40)$.

Following the above discussion on solving systems using Groebner bases, we first factorize $B_7 \in \mathbb{K}[z_7]$ (of degree 40), let $g$ be one of its irreducible factors, let $M/\mathbb{K}$ be the extension it defines, and let $Z_7 \in M$ be a root of $g$. Substituting this into $B_6 \in \mathbb{K}[z_6, z_7]$ we get $B_6(z_6, Z_7) \in M[z_6]$, which is linear, and let $Z_6$ be its root. Similarly we let $Z_5$ be the root of $B_5(z_5, Z_6, Z_7) \in M[z_5]$. Next, $B_4(z_4, Z_5, Z_6, Z_7) \in M[z_4]$ is quadratic, so we factorize it, let $h$ be one of its factors, let $L/M$ be the extension it defines, and let $Z_4 \in L$ be a root of $h$. Continuing, we find unique $Z_3$, $Z_2$ and $Z_1$ which together produces a solution $Z = (Z_1, \ldots, Z_7)$. Repeating this for all factors $g$ and $h$ we find all solutions $Z$ of the system (up to conjugacy) and the extensions $L/\mathbb{K}$ which they define.

If we are not in this generic case, then the Groebner basis is not of this form and there is some coincidence in the coordinates of some solutions of the 7 equations. If we apply a random Mobius transformation $x \mapsto ax + b$ to $x$ then the curve it defines is isomorphic to the original but the solutions $Z$ have moved, probably to the generic case. In practice, a small number of Mobius transformations is ever necessary to put the solutions into the generic case.

Remark 4.2. An algorithm of this sort would work with any ordering on \{z_1, \ldots, z_7\}. This ordering was chosen because it allows us to factor a degree-40 polynomial followed by a quadratic, which is somewhat faster than just factoring a degree-80 polynomial required for other orderings.

4.3. Provability. In practice, however, computing a Groebner basis of this sort is difficult. Groebner basis algorithms require exact fields, so in practice we represent $\mathbb{K}$ as a completion of a number field $\mathbb{K}$ at some place $p | 2$, and $f(x) \in \mathbb{K}[x]$.

The best known algorithm over number fields (and indeed the only algorithm which appears to run in feasible time on our problem) computes the basis modulo many primes and finds the global basis via the Chinese remainder theorem. The problem here is that a priori we cannot determine the size of the coefficients, and so a heuristic is used to decide if we have used enough primes to get the answer. The result is that the algorithm does not yield provable results. Nevertheless, it is possible to prove the output of the previous algorithm as follows.

Assuming the Groebner basis algorithm was correct, then any $Z = (Z_1, \ldots, Z_7)$ should be a solution to the original system of 7 equations (*) over $\mathbb{K}$. With the following version of Hensel’s lemma, we can show that $Z$ is indeed very close to a unique genuine solution, and we can say how close.
The following version of Hensel’s lemma is standard (see e.g. [19] Thm. 23 with \( t = \det J_f(b), s = v(f(b)) \) and \( vJ^i_f(b)f(b) \geq s \).

**Theorem 4.3** (Hensel’s lemma for multivariate systems). Suppose \( K \) is a local field and \( F = (F_1, \ldots, F_m) \in \mathcal{O}_K[z_1, \ldots, z_m] \) is a system of \( m \) equations in \( m \) variables over \( \mathcal{O}_K \) and \( Z = (Z_1, \ldots, Z_m) \in \mathcal{O}_K^m \). Let \( s = \min_i v_K(F_i(Z)) \) and let \( t = v_K J(F)(Z) \) where \( J(F) \) denotes the Jacobian determinant of \( F \) (the determinant of the \( m \times m \) matrix whose \((i,j)\)th entry is \( \frac{\partial F_i}{\partial z_j} \)). If \( s > 2t \) then there is a unique \( Z' \in \mathcal{O}_K^m \) such that \( F(Z') = 0 \) and \( \min_i v_K(Z'_i - Z_i) \geq s - t \).

Since evaluating resultants, Jacobians and polynomials are just basic arithmetic, these operations can be performed provably, and hence applying Hensel’s lemma we prove that each \( Z \) is indeed close to a unique solution \( Z' \) of the system of equations. Furthermore, Hensel’s lemma gives us a method to compute \( Z' \) to any prescribed precision. We expect that \( Z = Z' \) but we do not prove so.

It remains to check that these solutions \( Z' \) generate the fields \( L \) and that they are distinct up to \( K \)-conjugacy.

Recall that we have \( L/M/K \) with \( M = K(Z_7) \), \( g(x) \in K[x] \) the minimal polynomial for \( Z_7 \), and \( L = M(Z_4) \), \( h(x) \in M[x] \) the minimal polynomial for \( Z_4 \). We also have \( Z'_7, Z'_4 \in L \) and want to prove that \( L = K(Z'_7, Z'_4) \). Since we expect that \( Z'_7 = Z_7 \), then we expect \( Z'_4 \) is closer to \( Z_7 \) than any other root of \( g \), and so by Krasner’s lemma we conclude that \( M = K(Z'_7) \subset K(Z'_7) \). Another application of Krasner’s lemma on \( h \) and \( Z'_4 \) implies that \( L = M(Z_4) \subset M(Z'_4) \). Combining these, we deduce \( L = M(Z_4) \subset M(Z'_4) \subset K(Z'_4, Z'_7) \subset L \) and hence \( L = K(Z'_4, Z'_7) = K(Z') \).

To check Krasner’s lemma on a polynomial \( h \in K[x] \) and some \( Z \in \bar{K} \), note that it is equivalent to check that there is a root of \( h(x + Z) \) of higher valuation than all others. It is well-known that the Newton polygon of a polynomial measures the valuations of its roots, and therefore Krasner’s lemma is applicable if and only if the Newton polygon of \( h(x + Z) \) has a vertex with abscissa 1. This condition is explicitly checkable.

Finally, if \( Z_7 \) is a root of a factor \( g \) of \( B_7 \) and \( Y_7 \) is a root of a different factor of \( B_7 \), then \( g(Z_7) = 0 \neq g(Y_7) \), so if we check that \( v(g(Z'_7)) > v(g(Y'_7)) \) then we have proven that \( Z'_7 \neq Y'_7 \). Performing a similar check on pairs of \( Z'_4 \) determines that they are different. Together, this will prove that each pair of solutions is distinct.

By performing all these checks with large enough precision, we can determine whether or not the \( Z \) are a genuine set of distinct solutions generating the right fields. If any of these checks fails, then the Groebner basis algorithm was incorrect, and we should try the algorithm again with a lower heuristic chance of failure.

**Remark 4.4.** There is a conceptually simpler method for provability. Letting \( I \triangleleft \mathcal{K}[z_1, \ldots, z_7] \) be the ideal generated by the original system (\(*\)), and
letting $J$ be the ideal generated by the Groebner basis, then we wish to prove
that $I = J$. Since $J$ is generated by a Groebner basis, there is a normal
form for reduction modulo $J$ and hence we can check that each generator
of $I$ is zero mod $J$ and so deduce $I \triangleleft J$. Additionally we know a priori that
$I$ has precisely 80 solutions, and from the structure of the Groebner basis
that $J$ has precisely 80 solutions. Combined, this implies $I = J$.

We call this the **global proof method** to distinguish it from the **local proof
method** above. In practice, unless the coefficients of $f(x)$ are very small,
the global method takes much longer than the local method. Over $\mathbb{Q}$, with
small coefficients, the global method is typically around twice as quick, but
this benefit quickly diminishes as the field degree increases.

### 4.4. Tame conductor exponent revisited

In order to compute the tame conductor exponent using Theorem 3.2, we require
$\overline{d} = \dim J[3]^{G_0}$ and $|I|$. In previous sections we have already seen an algorithm to compute
$\dim J[3]^{G_u}$ for any $u$ having already computed $L_j/K$, so this is easy as a
side-effect of previous work.

For $|I|$, consider $e = \text{LCM}_{j} e(L_j/K)$, which again is easy to compute from
$L_j/K$. Clearly it is a divisor of $|I|$. The following lemma shows that $e$
is a good enough guess at $|I|$ in the sense that the statement of Theorem 3.2
depends only on $t$, $e$ and $\overline{d}$.

**Lemma 4.5.** Let $S = \{1, 2, 3, 4, 5, 6, 9, 10, 12, 18\}$. If $e \in S$ or $|I| \in S$ then
$|I| = e$. If $e = 80$ then $|I| = 160$. If $e \in \{8, 24\}$ then $|I| \in \{8, 24\}$. Otherwise
$e \in \{16, 32, 48, 64\}$ and $|I| \in \{16, 32, 48, 64, 96, 128, 192, 384\}$.

**Proof.** Properties of the Weil pairing imply that $I \triangleleft \text{Sp}_4(\mathbb{F}_3)$. Letting $W$
be the 2-Sylow subgroup of $I$, ramification theory implies $W \triangleleft I$ and $I/W$
cyclic. The lemma is proven by checking all groups $I$ consistent with these
facts. \hfill \Box

### 5. The algorithm

We use the following algorithm to compute the highest upper ramification break $\hat{u}(L/K)$. It takes as input the extension $L/K$ and returns the sequence
$(u_i, v_i, s_i)_{i=0}^{t}$ where $v_0 = -1 < v_1 < \ldots < v_t$ are the breaks in
the ramification filtration of $L/K$ in the lower numbering, $u_i$ are the cor-
responding breaks in the upper numbering, and $s_i = |\Gamma v_i|$ are the sizes of
the corresponding ramification subsets of the Galois set $\Gamma$ of $K$-embeddings
$L \rightarrow \bar{K}$. In particular, $\hat{u}(L/K) = u_t$.

See e.g. [15, §4–5] or [26, §3] for the definition of the ramification polynomial
(the coefficients of which have valuation $v_i$ in the algorithm), the
ramification polygon $P$ and its connection to the ramification filtration of
$L/K$. See e.g. [18] for the connection of this filtration to the upper and
lower ramification breaks and the Galois set $\Gamma$. 

1: (Compute the ramification polygon of $L/U$)
2: $U \leftarrow$ the maximal unramified subextension of $L/K$
3: $e \leftarrow (L : U)$
4: $E \leftarrow$ a defining Eisenstein polynomial for $L/U$
5: $r_i \leftarrow \min_{j=1}^{e-1} v(E_j) + \frac{i}{e}$ for $i = 1, \ldots, e$
6: $P \leftarrow$ the lower convex hull of the points $(i, r_i)$ for $1 \leq i \leq e$
7: (Compute $u_i, v_i$ and $s_i = |\Gamma v_i|$)
8: $u_0 \leftarrow -1$
9: $v_0 \leftarrow -1$
10: $s_0 \leftarrow (L : K)$
11: $t \leftarrow$ the number of faces of $P$
12: for all $i = 1, \ldots, t$ do
13: $F \leftarrow$ the $i$th face of $P$ from the right
14: $v_i \leftarrow$ the negative of the gradient of $F$
15: $s_i \leftarrow$ the abscissa of the right hand vertex of $F$
16: $u_i \leftarrow u_{i-1} + \frac{s_i-1}{s_0}(v_i - v_{i-1})$
17: end for
18: return $((u_i, v_i, s_i))_{i=0}^{t}$

Now we present the final algorithm, which takes a polynomial $f(x) \in K[x]$ of degree 5 or 6 over a number field $K$ defining a hyperelliptic curve $y^2 = f(x)$, and a prime ideal $p$ of $K$ dividing 2, and returns the conductor exponent $n_p$ of the curve at $p$.

1: (Apply Moebius transformations to $f(x)$ until its 3-torsion points are in general position)
2: repeat
3: choose $a, b, c, d \in \mathbb{Z}$ so that $ad - bc \neq 0$
4: $\tilde{f} \leftarrow f\left(\frac{ax+b}{cx+d}\right)(cx+d)^6$
5: $F = (F_i)_{i=1}^7 \leftarrow$ coefficients of
\[
(z_1 + z_2 x + z_3 x^2 + z_4 x^3)^2 + z_7(z_5 + z_6 x + x^2)^3 - \tilde{f}(x)
\]
6: $B = (B_i)_i \leftarrow$ Groebner basis of $F$
7: until $B$ is in generic form
8: (Find the fields defined by each $Z_7$)
9: $K \leftarrow K_p$
10: $S \leftarrow$ empty sequence
11: $C \leftarrow$ empty sequence
12: $(g_i)_i \leftarrow$ irreducible factorization of $B_7(x)$ over $K$
13: for all $g_i$ do
14: $M \leftarrow$ the extension of $K$ defined by $g_i$
15: $Z_7 \leftarrow$ a root of $g_i$ in $M$
16: $Z_6 \leftarrow$ the root of linear $B_6(x, Z_7)$ over $M$
17: $Z_5 \leftarrow$ the root of linear $B_5(x, Z_6, Z_7)$ over $M$
Find the fields defined by each \( Z_4 \)

\[(h_i)_i \leftarrow \text{irreducible factorization of } B_4(x, Z_5, Z_6, Z_7) \text{ over } M \]

for all \( h_i \) do

\[ L \leftarrow \text{the extension of } M \text{ defined by } h_i \]
\[ Z_4 \leftarrow \text{a root of } h_i \text{ in } L \]
\[ Z_3 \leftarrow \text{the root of linear } B_3(x, Z_4, Z_5, Z_6, Z_7) \text{ over } L \]
\[ Z_2 \leftarrow \text{the root of linear } B_2(x, Z_3, Z_4, Z_5, Z_6, Z_7) \text{ over } L \]
\[ Z_1 \leftarrow \text{the root of linear } B_1(x, Z_2, Z_3, Z_4, Z_5, Z_6, Z_7) \text{ over } L \]

(Check the solutions are valid with Hensel's lemma)

assert \( Z \) is Hensel liftable to a solution of \( F \)

\[ Z' \leftarrow \text{the Hensel-lifted solution} \quad \text{(we expect } Z' = Z \text{)} \]

(Check the solutions generate the right fields with Krasner's lemma)

assert the Newton polygon of \( g_i(x + Z_7') \) has a vertex above 1

assert the Newton polygon of \( h_j(x + Z_4') \) has a vertex above 1

(Check the solutions are distinct)

for \((Y_7', Y_4') \in C\) do

assert \( v_K(g_i(Z_7')) > v_K(g_i(Y_7')) \) or \( v_K(h_i(Z_4')) > v_K(h_i(Y_4')) \)

end for

(Save \( L \))

append \( L \) to \( S \)

end for

(Compute the tame and wild exponents from \( S \))

\[ \tilde{d} \leftarrow \text{the function } u \mapsto \log_3(1 + \sum_{L \in S : u(L/K) \leq u(L : K)} \dim \overline{V^u}) \]
\[ e \leftarrow \text{LCM}_{L \in S} e(L/K) \]
\[ t \leftarrow \text{potential toric dimension of } J \]

if \( \tilde{d}(0) = 0 \) then

\[ n_{tame} \leftarrow 4 \]

else if \( \tilde{d}(0) = 4 \) then

\[ n_{tame} \leftarrow t \]

else if \( t = 0 \) then

if \( e = 3 \) and \( \tilde{d}(0) = 2 \) then

\[ n_{tame} \leftarrow 4 \]

else

\[ n_{tame} \leftarrow \text{smallest even integer } \geq 4 - \tilde{d}(0) \]

end if

else if \( (t, e) \in \{(1, 3), (2, 3), (1, 2), (1, 6)\} \) then

\[ n_{tame} \leftarrow \text{the tame exponent, computed from a regular model} \]

else if \( (t, e) = (2, 9) \) then

\[ n_{tame} \leftarrow 4 \]

else
\begin{verbatim}
60: \ n_{tame} \leftarrow 3
61: \ \textbf{end if}
62: \ u_0, \ldots, u_t \leftarrow \text{the sorted elements of } \{ \hat{u}(L/K) : L \in S \} \cup \{-1, 0\}
63: \ \n_{\text{wild}} \leftarrow \sum_{i=2}^{t} (u_i - u_{i-1})(4 - \hat{d}(u_i))
64: \ \text{return } \n_{\text{wild}} + \n_{\text{tame}}
\end{verbatim}

**Remark 5.1.** Note that the approach to solving the system of 7 equations in 7 variables is to compute a Groebner basis globally, and then solve this system locally. This is the only global aspect of the algorithm, and becomes the bottleneck when the global coefficients become large. An alternative approach is to solve the system of equations directly locally, perhaps using a Montes-type algorithm similar to univariate factorization algorithms which split the system into several smaller systems. This is the subject of ongoing research [11].

**Remark 5.2.** Recalling Remark 4.4, if we wish to use the global proof method instead, then we can skip over lines 22–36 and instead insert after line 7 a check that each element of $F$ reduces to 0 modulo $B$.

6. Implementation

The algorithms described in this paper have been implemented [13] in the Magma computer algebra system [2] using a customized implementation of $p$-adics which removes most $p$-adic precision considerations from the user [12]. The implementation, modulo bugs, produces provable results at every step.

The LMFDB [23] contains the 66,158 genus 2 hyperelliptic curves defined over $\mathbb{Q}$ computed by Booker et al [1]. Of these, all but 1113 have discriminant of 2-valuation less than 12 and therefore their conductor exponent at 2 is computable via Ogg’s formula. Our algorithm has been run on the 1113 remaining curves, using the global proof method (see Remark 4.4). The computation took 9.4 core-hours in total on a 2.7GHz Intel Xeon, averaging 30 core-seconds per curve.

For all but 6 of these curves, the fast tame conductor algorithm of §3 succeeds, and so we compute an entire conductor exponent at 2. For 4 of the remaining 6 curves, a regular model was quickly computed by Magma (taking at most 10 seconds) and therefore the tame exponent was deduced this way. For the remaining 2 curves (labelled 3616.b.462848.1 and 18816.d.602112.1 in the LMFDB) a regular model was computed by hand. In all of these cases, the exponent agrees with the unproven results of [1] and therefore we have proven the conductors for all curves in the LMFDB.

The run-time of the algorithm is usually dominated by the factorization of the degree-40 polynomial over $K$, at least when the defining polynomial $f(x)$ has fairly small coefficients. When these coefficients grow, the (global) Groebner basis algorithm dominates the run-time.
This gives some impetus towards developing a fully local algorithm as suggested in Remark 5.1 since this will be independent of global coefficient sizes.

The implementation has also been tested on some curves defined over quadratic number fields. These results were confirmed by Schembri [29] by finding a corresponding Bianchi modular form whose level squared equals the conductor and proving the expected relationship between their \( L \)-functions using Faltings-Serre.

The run-time does not appear to grow much with the conductor exponent, as evidenced by the following graph summarizing the run-times of the algorithm on the LMFDB curves. It plots the mean run-time for each conductor exponent with a thick black line, and plots the 20-percentiles with thin gray lines.

![Graph summarizing run-times of the algorithm on the LMFDB curves.](image)
