Abstract

Fibroblast growth factor receptor 3 (FGFR3), highly conserved in both humans and murine, is one of the key tyrosine kinase receptors for FGF. FGFR3 is expressed in different tissues, including cartilage, brain, kidney, and intestine at different development stages. Conventional knockout of $Fgfr3$ alleles leads to short life span, and overgrowth of bone. In clinic, human FGFR3 mutations are responsible for three different types of chondrodysplasia syndromes including achondroplasia (ACH), hypochondroplasia (HCH) and thanatophoric dysplasia (TD). For better understanding of the roles of FGFR3 in different tissues at different stages of development and in pathological conditions, we generated $Fgfr3$ conditional knockout mice in which loxp sites flank exons 9-10 in the $Fgfr3$ allele. We also demonstrated that Cre-mediated recombination using Col2a1-Cre, a Cre line expressed in chondrocyte during bone development, results in specific deletion of the gene in tissues containing cartilage. This animal model will be useful to study distinct roles of FGFR3 in different tissues at different ages.

Key words: FGFR3; conditional knockout; Cre-Loxp; gene targeting

Introduction

Fibroblast growth factor receptor 3 (FGFR3) is one of the four membrane-spanning receptor tyrosine kinases that serve as high affinity receptors for multiple fibroblast growth factors [1]. $Fgfr3$ is mainly expressed in cartilage, and negatively regulates bone growth [2, 3]. Gain-of-function mutations in human FGFR3 lead to three types of chondrodysplasia syndromes including achondroplasia (ACH), hypochondroplasia (HCH) and thanatophoric dysplasia (TD) [4-9]. Recently partial loss-of-function mutation of FGFR3 was found to cause camptodactyly, tall stature, scoliosis, and hearing loss (CATSHL) syndrome [10]. The expression of $Fgfr3$ is also detected in other organs such as kidney, intestine, brain, spinal cord and so on [11-14], which indicates that FGFR3 could regulate the development and physiological and pathological functions of these cells.

To explore the roles of FGFR3 in development and diseases, mouse models with genetic modification of FGFR3 have been generated [1-3, 15-18]. Deng and Colvin, etc have independently generated conventional $Fgfr3$ knock out mouse models [2, 3] or...
model with deficiency in a specific isoform [18], which have been used to study the role of FGFR3 in a variety of developmental and disease processes [2, 19-21]. In these conventional knock out mice, Fgfr3 is disrupted in all cells, which prevents the effort for further studying of the role of FGFR3 in specific types of cells and their corresponding cellular and molecular mechanisms. For example, it is difficult to know if the decreased bone mass in Fgfr3 null mice [20] is secondarily related to the altered chondrogenesis and/or directly related to changes in osteogenesis [2, 3], because both chondrogenesis and osteogenesis were found changed in Fgfr3 knock out mice [16, 20]. Furthermore, in certain genetic background, the lifespan of Fgfr3 null mice is relatively shorter than their normal littermates [20], which prevents us from studying the role of FGFR3 in later development and diseases in adult stages such as aging related diseases. In addition, in conventional Fgfr3 knock out mouse models, the morphology structure of tissue has significant changes during early development stage. It is impossible to exclude the potential role of already changed tissue in the pathogenesis of regeneration and healing. To overcome these disadvantages, we have generated a Fgfr3 conditional null allele, the Fgfr3flox allele.

The mouse Fgfr3 gene contains 19 exons and spans about 25 kb on chromosome 5. The protein product of FGFR3 is encoded by exons 2-18 [22]. As for FGFR3, alternative splicing of the second half of the third Ig domain produces two isoforms, IIIb (encoded by exons 7 and 8) and IIIc (encoded by exons 7 and 9) [23]. The transmembrane domain is encoded by exon 10. Deletion of exons 9 and 10 is expected to cause loss of function of both IIIb and IIIc isoform of FGFR3.

Materials and Methods

Generation of the Fgfr3floxneo allele

The targeting vector was constructed using Fgfr3 genomic DNA isolated previously [3]. The plloxPneo vector was described previously [24]. Briefly, in the targeting vector, the 3.8-kb fragment including intron 10 to part of exon 19 was inserted into plloxPneo vector using Not I and Sma I to generate the 3’ homology recombination arm. The 5’ homology recombination arm in the targeting vector was generated by inserting the 5.5-kb Cla I-Xba I fragment including part of intron 2 to intron 10 and the third Loxp was inserted into intron 8 of the Fgfr3 locus. The finished targeting construct, Fgfr3floxneo, is shown in Figure 1a.

Electroporation of ES cells and generation of germline chimeras

TC1 embryonic stem (ES) cells [3] were transfected with Not I-digested plloxPneoFgfr3 by electroporation and selected using G418 and -(2-deoxy-2-fluoro-β-D-avabinofuranosyl-5-iodouracil (FIAU). The homologous recombination events within the Fgfr3 locus from both G418- and FIAU-resistant ES clones were analyzed by Southern blot using the 5’ external probe with Spe I-digested DNA. The 5’ probe is a 1.9-kb BamH I-Sac I fragment specific to the Fgfr3 sequence. The third Loxp was identified by PCR using primer p1 (5’-GATGCCTCAACAAATACTGGTAG CCC-3’) and p2 (5’-CCAGACAGATGGAGCA GGAA-3’). Cells heterozygous for the targeted mutation were microinjected into blastocysts from C57/B6 mice to obtain germ-line transmission following standard procedures.

Genotype analysis

The chimeric males were bred to C57BL/6 females, and F1 agouti offspring were analyzed by PCR for the presence of the Fgfr3floxed allele. Genotypes of the mice bearing the Fgfr3floxed, Fgfr3lox, Fgfr3null and wild-type allele were determined by PCR analysis as illustrated in Figure 2 and 3. The primers are p3 (5’-GCTCCCTGTCTCCTGCTG-3’), p4(5’-CAGCT CATTCCTCCACTCATGAT-3’) and p5 (5’-TGTTAAAAAGGGTTGGGTGTTAG-3’).

Skeletal preparation and histology.

Mice at P15 were sacrificed. The femurs were fixed overnight in 4% paraformaldehyde at 4°C and rinsed in PBS and decalcedified in 15% EDTA (pH 7.4) for 10-15 days before embedding in paraffin as described previously. Six-micron thick sections were used for H.&E. staining. High-resolution X-ray of femurs (5’-TGTTAAAAAGGGTTGGGTGTTAG-3’). Cells heterozygous for the targeted mutation were microinjected into blastocysts from C57/B6 mice to obtain germ-line transmission following standard procedures.

RNA extraction and RT-PCR

RNA was extracted from brain of mice using Trizol (Invitrogen) reagent according to the manufacturer’s instructions. Single strand cDNA was synthesized from 1 µg of total RNA using RNA reverse transcriptase kit (Takara). The mRNA level of Fgfr3 was detected by primer FGFR3-F(5’-CAAGGACTAGAG-3’) and FGFR3-R (5’-CCGTGACAGGCTTGGCAGTA-3’). The β-actin gene was detected by primer β-actin-F (5’-TTGTACCACTGGAGCAATGGG-3’) and β-actin-R (5’-GATCTTTGATCATTGCAGTG-3’) was an internal control.

(a) Mice containing Fgfr3flxneo alleles were crossed with Ella-Cre transgenic mice resulting in three kinds of deletion between three Loxp sites (b-d). Position of primers was also marked. (b) Primer p1 and p5 amplify fragments of 390 bp from Fgfr3null allele with deletion exons 9-10 and neo between Loxp1 and 3 (1/3), no amplification for the wild type (WT). (c) Primer p1 and p4 amplify fragments of 408 bp from Fgfr3neofloxed allele with deletion exons 9-10 between Loxp2 and 3 (2/3), no amplification for WT. (d) Primer p3 and p5 amplified fragments of 320 bp from Fgfr3floxed allele with deletion neo between Loxp1 and 2 (1/2), but only 260bp from WT. n, Fgfr3null allele; nf, Fgfr3neofloxed allele; f, Fgfr3floxed allele; w, wild type.

Results and Discussion

To construct the Fgfr3flxneo allele, we have made a targeting vector that contains two Loxp sites flanking the entire exons 9 and 10. In this way, existence of Cre recombinase would lead to deletion of exons 9 and 10, and subsequent inactivation of FGFR3. We inserted a 5.5-kb fragment including exons 3-10 and the third Loxp (located in intron 8) into ploxPneo vector [24] as the 5' homology recombination arm, then put a 3.8-kb fragment containing exons 10 to 19 into ploxPneo to form 3' homology recombination arm (Fig. 1a). The Not I-linearized targeting vector Fgfr3flxneo was transfected into TC1 ES cells by electroporation. Two targeted ES clones were detected by Southern blot using a 5' flanking external probe (Fig. 1a and b). The third Loxp in the ES clones was identified by PCR (Fig. 1a and c), which confirmed that Fgfr3flxneo allele in the two targeted ES clones containing the third Loxp. These two positive ES clones were microinjected into blastocysts harvested from C57/BL6 mice according to standard protocols.

We first assessed if the recombination of Fgfr3 in mice is correct. Since we previously found in the Fgfr3neoG369C/neoG369C mice showed phenotypes similar to those of Fgfr3-null (Fgfr3+/−) mice [16]. We generated Fgfr3flxneo/flxneo mice by crossing Fgfr3flxneo/flxneo heterozygous mice. PCR was used to identify Fgfr3flxneo/flxneo mice (Fig. 2a and b). RT-PCR analysis revealed that there was no Fgfr3 expression in Fgfr3flxneo/flxneo mice (Fig. 2c). We also found that Fgfr3flxneo/flxneo mice indeed showed skeleton phenotype including crooked tail and increased height of growth plates (Fig. 2d and e), which is similar to the phenotype of Fgfr3−/− mice [2, 3]. These results indirectly demonstrated the correct recombination of the targeting construct.

To test whether neo gene and exons 9-10 in Fgfr3flxneo allele can be deleted by the Cre recombinase, heterozygous (Fgfr3flxneo+/−) mice were crossed with Ella-Cre transgenic mice that express Cre recombinase in germline [25, 26]. The offspring were identified by PCR with primers shown in Figure 3a. As expected, we found that this crossing breeding generated three types of alleles due to Cre-mediated recombination among three Loxp sites. A 390bp fragment was amplified from Fgfr3null allele with deletion of neo gene and exons 9-10 between Loxp1 and Loxp3 (confirmed by sequencing) (Fig. 3b). Fgfr3neofloxed allele with deletion of exons 9-10 was detected by producing an amplified 408bp fragment (Fig. 3c). The PCR-amplified 320 fragment indicated the excision of the neo gene, which
produced a Fgr3<sup>flox</sup> allele (conditional knockout allele) in Fgr3<sup>flox/+</sup> heterozygous mice (Fig. 3d).

To further determine the correction of Fgr3 recombination in mice, we generated homozygous Fgr3 null mice. RT-PCR analysis showed that there was no expression of Fgr3 in the brain (Fig. 4a). These mice showed increased length of long bone and decreased bone mineral density (Fig. 4b and c), which is also similar to the phenotypes of Fgr3 knock out mice [3, 20]. Finally we crossed the Fgr3<sup>flox/+</sup> mice with mice that carry a Col2a1-Cre transgene to assess the activity of Fgr3 conditional knockout allele. The result indicated that the Cre-mediated deletion occurs in several tissues that contain cartilage, including the tail, and knee joint, but not in other tissues where the Col2a1-Cre transgene is not expressed, such as the lung, liver, and spleen (Fig. 4d). These data indicate that the Fgr3<sup>flox</sup> allele can be recombined to delete exons 9-10 in a tissue-specific fashion, thus the Fgr3 conditional mouse model should be very useful for studying Fgr3 functions during later stages of development.

**Figure 4.** Identification of Fgr3 null mice and validation of Fgr3 conditional knockout allele. (a) There was no expression of Fgr3 in brain RNA of Fgr3 null mice (homozygous mice with both exons 9-10 and neo deleted in Fgr3). (b) The length of femur in 3-month-old Fgr3 null mice was longer than that in wild-type mice. (c) X-ray analysis showed increased length and decreased bone mineral density of femur from Fgr3 null mice (Arrows). (d) Tissue-specific inactivation of the Fgr3 conditional allele by a Col2a1-Cre transgene in tissues containing cartilage was revealed by PCR analysis using primer pair p3/p5, which amplifies about 320 bp from the unrecombined allele, and primer pair p1/p5, which amplifies about 390 bp from the recombined allele.

**Conclusion**

The results indicate that we successfully generated a mouse model for conditional deletion of Fgr3, which will help to explore the role of FGFR3 in development and the related skeletal diseases.
