Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company’s public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Severe cerebral involvement in adult-onset hemophagocytic lymphohistiocytosis

Farid Radmanesh a,b,1, Alicia Rodriguez-Pla c,1, Michael D. Pincus d, Joseph D. Burns b,e,*

1. Case report

1.1. Patient 1

A 46-year-old woman was admitted with a 3-month history of dyspnea, dysphagia and a generalized, maculopapular, and pruritic rash. She was febrile, tachycardic, and tachypneic. Neurological examination was normal. Her neurological status progressively worsened, and within 48 h, she was alert, but followed no commands, anarthric, had significant spasticity, hyperreflexia and myoclonus. CT head (Fig. 1A) and cerebrospinal fluid (CSF) analysis were unremarkable.

On hospital day (HD) 3, she developed coma with conjugate depressed gaze, intact brainstem reflexes and flexor posturing to pain. She was intubated and developed distributive shock. CT head showed bilateral symmetric thalamic hypodensities (Fig. 1B), chronic hypoxic and pyknotic neurons. CT head revealed diffuse, severe cerebral edema with central transtentorial and transforaminal herniation (Fig. 1C). Life support was discontinued. Posthumously, elevated soluble CD25 (5950 pg/mL, Ref <=1033) and phagocytic histiocytes on bone marrow biopsy (H-score 98%) confirmed HLH. Post-mortem brain examination revealed diffuse edema, normal vessels, and early softening and discoloration of the bilateral thalami with prominent eosinophilic and pyknotic neurons.

1.2. Patient 2

A 44-year old woman presented after a 5-day outside hospitalization for fever, right upper quadrant abdominal pain, and transaminitis that rapidly progressed to altered consciousness, hypoxia, acute respiratory distress syndrome (ARDS), distributive shock, anuric renal failure, and disseminated intravascular coagulation (DIC). She required intubation and received empiric antibiotics for presumed cholecystitis and septic shock and was transferred to our hospital.

Neurologic examination on arrival revealed coma, intact brainstem reflexes, flaccid quadriplegia, and diffuse hyperreflexia. Innumerable punctate hemorrhages throughout the cerebral hemispheres were seen in the CT head and brain MRI (Fig. 1D-F). Labs revealed anemia, thrombocytopenia, elevated creatinine of 5.2 mg/dL, transaminitis, triglycerides of 559 mg/dL, CK of 555 IU/L, LDH of 697 IU/L and ferritin of 4,921 ng/mL. Blood cultures were negative. High-dose dexamethasone was started for suspected HLH. Etoposide was added after bone marrow biopsy was consistent with HLH. She slowly improved, was extubated on HD 19 and at 2 months was living at home with a modified Rankin score of 2.
2. Discussion

We report two cases demonstrating different and rare forms of severe brain involvement in adult patients with HLH: ANE, and diffuse hemorrhagic disease due to DIC.

Severe HLH with brain involvement in adults is rare. A retrospective study found that 10% of 289 adult patients with HLH had central nervous system (CNS) involvement [2]. CSF and neuroimaging findings are typically unspecific [2].

ANE is an uncommon but distinctive type of acute, severe brain injury. ANE in children but not in adults with HLH has been reported [3]. Therefore, we herein describe the first case of an adult patient with HLH presenting with fulminant ANE.

DIC has been described in 50% of the patients in a series of critically ill HLH patients admitted to intensive care unit [4]. Brain hemorrhage in adult patients with HLH was found in only 1 out of 289 adult patients with HLH [2]. Our patient presented with DIC resulting in rapid progression to multiple intracerebral hemorrhages with coma. Early suspicion of the underlying diagnosis prompted us to start timely treatment, which resulted in functional neurological recovery of the patient.

Clinical manifestations, labs and imaging findings of HLH with CNS involvement are non-specific [1]. Early diagnosis and treatment is important to prevent serious complications and demise. Such diagnosis should be considered in patients with sepsis-like illness in the absence of an identifiable infection and disproportionately severe neurological manifestations. The existence of the HLH-like cytokine storm syndrome in adult patients with COVID-19 infection [6] which has, in at least one published case led to ANE [7], elevates the importance of a raised index of suspicion for these forms of severe cerebral injury in patients with COVID-19 infection.
