Three new hypogean species of the false scorpions genus *Ephippiochthonius* Beier, 1930 (Arachnida: Pseudoscorpiones: Chthoniidae) from the Crimean Peninsula

**ABSTRACT.** Three new hypogean species of the false scorpions genus *Ephippiochthonius* Beier, 1930 from the caves of the Crimean Peninsula, i.e. *E. tauroscythicus* sp.n., *E. volkeri* sp.n. and *E. pliginskyi* sp.n. are described. Diagnostic and ecological features of these species are presented and discussed, as well as compared with the related species of this genus. A hypothesis about a possible scenario of speciation of trogloomorphic species of the genus *Ephippiochthonius* in the caves of the Crimean Mountains in connection with global climate changes is proposed.

**REЗЮМЕ.** Описывается три новых гипогеальных видов ложных скорпионов рода *Ephippiochthonius* Beier, 1930 из пещер Крымского полуострова — *E. tauroscythicus* sp.n., *E. volkeri* sp.n. и *E. pliginskyi* sp.n. Приводятся и обсуждаются диагностические и экологические особенности этих видов, а также сравниваются с близкими видами этого рода. Высказывается гипотеза о возможном сценарии видообразования трогломорфных видов рода *Ephippiochthonius* в пещерах Горного Крыма в связи с глобальными климатическими изменениями.

**Introduction**

The fauna of false scorpions of the Crimean Peninsula has been poorly studied, moreover the available studies are represented by a small number of taxonomic [Redikorzev, 1918; Lebedev, 1927; Ćurčić, 1984; Zaragoza, 2010; Kolesnikov, Turbanov, 2017, 2018; Turbanov, Kolesnikov, 2020] and faunistic [Lebedinšky, 1904; Ellingsen, 1910; Lebedev, 1914; Pliginsky 1927; Chamberlin, 1949; Schawaller, 1989; Dashdamirov, 1999; Turbanov, Kolesnikov, 2015] publications. The above mentioned publications do not represent the true diversity of false scorpions of the Crimea, a region of the Eastern Mediterranean with a rich biodiversity. However, during the study of the cave biota of the Crimea, we found a number of false scorpions species that belong to the family Chthoniidae Daday, 1888 and identified them as representatives of the genus *Ephippiochthonius* Beier, 1930.

Recently the genus *Ephippiochthonius* was erected as a valid taxon by Zaragoza [2017]. The genus is widely distributed across the Mediterranean and Macaronesian region, reaching Iran to the east, and Scandinavia to the north. There are records of this genus from other parts of the world (North and South America,
Fig. 1. Map of collection sites (caves) for the three species of the genus Ephippiochthonius in the Crimean Mountains: *E. tauroscythicus* sp.n. (yellow circle) — Tshernoretshenskaya Cave; *E. volkeri* sp.n. (blue diamond) — Syundyuryu-Kobasy (= Syundyuryu) Cave; *E. pliginskyi* sp.n. (green square) — Kizil-Koba (= Krasnaya) Cave.

**Materials and methods**

**SAMPLING AND REPOSITORIES.** Totally, six specimens of the described three new species of the genus *Ephippiochthonius* from three caves of the Crimean Mountains have been studied (Fig. 1), a part of which was collected by the first author: two specimens of *E. tauroscythicus* sp.n. from Tshernoretshenskaya Cave (Baydarsko-Balaklavsky Karst Massif), and three specimens of *E. volkeri* sp.n. from Syundyuryu-Kobasy (= Syundyuryu) Cave (Ai-Petri Karst Massif); and also one specimen of *E. pliginskyi* sp.n. from Kizil-Koba (= Krasnaya) Cave (Dolgorukovsky Karst Massif) described in Pliginsky [1927] article as *E. tetrachelatus* and stored at the ZISP. Cave biotopes, inhabited by the described new species of the genus *Ephippiochthonius*, are presented in Fig. 2.

The type material is deposited in the Zoological Museum of Moscow University (ZMUM), Zoological Institute of the Russian Academy of Sciences, Saint Petersburg (ZISP), and the private collections of I. Turbanov (IT).

**MORPHOLOGICAL CHARACTERS AND TERMINOLOGY.** All pseudoscorpions collected were fixed in 96% ethyl alcohol. For morphological examination under a light microscope, they were cleaned in pure lactic acid and temporarily mounted on microscopic slides. Some specimens were dissected for a more detailed study of the chelicerae and pedipalps. All measurements were taken with an ocular micrometer using the reference points proposed by Chamberlin [1931] and expressed in millimeters, followed by standard ratios in

Hawaii, Cuba, Seychelles, and southwestern Australia). Gardini [2013] revised the Italian species of this genus; Zaragoza [2017] revised the species of this genus in the Iberian Peninsula, the Balearic Islands and Macaronesia. In the Eastern Mediterranean regions located near the Crimea, representatives of the genus *Ephippiochthonius* are known from the Caucasus and adjacent regions [Schawaller, 1983; Schawaller, Dashdamirov, 1988; Kolesnikov et al., 2019; Nassirkhani et al., 2019].

For the Crimean Peninsula, for the first time, representatives of the genus *Ephippiochthonius* are quoted by Lebedinsky [1904] as *Obisium abeillei* (Simon, 1872) (= *Neobisium* (*Blothrus*) abeillei (Simon, 1872) in the modern representation) from Kizil-Koba (= Krasnaya) Cave. Later, Pliginsky [1927] collected *E. tetrachelatus* (Preyssler, 1790) in the same cave, showed referring to the definition and opinion of V.V. Redikorzev, that the identified and illustrated by Lebedinsky [1904] *O. abeillei* should be classified as *E. tetrachelatus*. Moreover, Ellingsen [1910] points to the presence of *E. tetrachelatus* in the terrestrial biotopes the region of Alushta.

However, the above given indications of the widespread *E. tetrachelatus* in the Crimea are likely to be wrong and could be in fact a group of species [Dashdamirov, Schawaller, 1993; Gardini, 2013; Zaragoza, 2017; Kolesnikov et al., 2019], which is partly confirmed by this study.

Three new hypogean species false scorpions of the genus *Ephippiochthonius* from the Crimean Peninsula are described and illustrated in this paper.

parentheses. The ratios provided were: length to width for carapace, chelicerae and pedipalps, except in the case of the chela and its hand, for which the depth was used instead of width [Mahner, 2011]. We applied terminology used by Chamberlin [1931], with amendments proposed by Harvey [1992], and Judson [2007]. The chaetotactic formulae of the carapace and chelicerae are given according to Gabbott & Vachon [1963]. The terms “sublateral ocular seta” (osl), “lateral ocular seta” (of), “posterolateral dorsal row”, “lateral row”, “median row” and “anterior dorsal row” were used in accordance with the interpretation of Gabbott & Vachon’s [1963] for the ocular row and femoral chaetotaxy. Tactile setae on tergites IX and XI and sternite X are frequently lost in preserved specimens. In such cases their tactile nature was determined by a larger diameter of the areolar insertion in comparison with other setae on the same segment and no measurement data were provided. Following Gardini [2013, 2014], measurements of the pedipalpal trochanter and of all parts of legs I and IV were excluded because they added too little meaningful information.

Abbreviations used in text and figures: af and am — spot sensilla; al — anterolateral seta of carapace; ame — anteromedial seta of carapace; as — antiaxial sensory setae; cs — cheliceral spinneret; di — isolated subapical tooth of movable cheliceral finger; dps — distal marginal seta of pedipal; eh — edge; fa — antiaxial lyrifissure of fixed chelal finger; fb — basal lyrifissures of fixed chelal finger; fd, fd1, fd2, — dorsal lyrifissures of the fixed chelal finger; hl — distal lyrifissure of chelal hand; hp — proximal lyrifissure of chelal hand; ip — intercondylar protuberance; ld, ldst, — antiaxial lyrifissures associated with chelical setae db, dt, db, and vt, respectively; m — microseta; ma, ma1, ma2, — antiaxial lyrifissures of movable chelal finger; ol — lateral ocular seta of carapace; om — medial ocular seta of carapace; oxl — sublateral ocular seta of carapace; pe — coupled sensilla of movable chelal finger; pl — posteralateral seta of carapace; pm — postero medial seta of carapace; sp — subdiscal protuberance; T — tactile seta; td — accessory tooth of movable chelical finger.

**Taxonomic part**

*Ephippiochthonius tauroscythicus* sp.n. Fig. 3.

**HOLOTYPE** ♂ (ZMUM TI-61), Crimean Peninsula, region of Sevastopol, canyon of Teshma River, Teshmareshenskaya Cave, 5 May 2017, leg. I.S. Turbanov.

**PARATYPE:** 1 ♀ (ZMUM TI-62), same cave and collector, together with holotype, 3 March 2018.

**DISTRIBUTION.** Known from the type locality so far.

**NAME.** Named after the Tauroscytians (ancient Greek Ταυροσκύθας or Ταυροσκύθες, Latin Taurocythae), the people who inhabited the Crimean Mountains from the end of the 3rd century BC to the 4th century AD.

**DIAGNOSIS** (♀, ♂ unknown). A large hypogean *Ephippiochthonius* that differs from other species of the *tetrache-latus*-group in the following combination of characters: anterior eyes with convex lens, posterior eyes reduced to a smooth cuticular area; movable cheliceral finger without a small isolated subapical tooth (di); spinneret (cs) present; carapace with a short epistome; lateral ocular setae, sublateral ocular setae and anterolateral setae approximately of equal length; posteralateral seta (pl) of carapace absent; pedipalpal hand (lateral view) with weak depression at the level of ib/ish and an abrupt slope between trichobothria ib/ isb and eb; fixed and movable chelal fingers respectively with 23–24 and 8–9 triangular teeth; fixed chelal finger at level of est-it with 3 teeth occupying 0.1 mm (distance between successive apices 0.040–0.045 mm); proximal half of movable chelal finger smooth, without dental canals; sensilla pc well distal of sb; trichobothrium ist level with esb (esb slightly distal of ist) and well proximad of lyrifissure fb; length of chela 1.30–1.31 mm, length of movable chelal finger 0.74–0.75 mm; chela 5.20–5.69 times as long as deep; ratio of pedipalpal femur/carapace 1.53–1.61.

**Description of adults** (♀, ♂ unknown). Large, hypogean, moderately troglomorphic species. Integument depigmented; weakly hispid granulation on lateral surfaces of carapace, on cheliceral hand and on bases of chelal fingers.

Carapace not longer than broad and constricted posteriorly; anterior margin (Figs 3A–C) closely dentate between median macrosetae, with a weakly prominent epistome; ocular area as in Fig. 3A, anterior eyes with convex lens (diameter 0.050 mm), posterior eyes reduced to a smooth cuticular area (diameter 0.030–0.032 mm), all eyes with tapetum; distance from anterior eyes to anterior margin of carapace 0.500–0.055 mm; distance between anterior and posterior eyes 0.079–0.085 mm. Chaetotaxy: 18 macrosetae and 2 precoxal microsetae (m) (sometimes on one side there can only be 1 microseta) on each side, posterior row with 2 medial macrosetae (pm), postero lateral seta (pl) absent, macrosetae thin; setal formula: mm4mm:6.4:2.2 (rarely mm4m:6.4:2.2), anteromedial setae 0.16 mm long, anterolateral setae 0.13–0.15 mm long, sublateral ocular setae 0.12 mm long, lateral ocular setae 0.14–0.15 mm long; 4 lyrifissures anteriorly and 2 posteriorly.

Chaetotaxy of tergites: 4:4:4.4:6:6:6:1T2T1:4:1T2T1:0.

Chaetotaxy of sternites: 10(3):3(3):27–82:2m6m:m5–6m5m5m5m5m5m5m5:6.6:6:6:1T2T1:4:1T2T1:0.

Chaetotaxy of sternites of 3D–F: F with 6 setae and 2 lateral microsetae; seta vb 0.055–0.056 mm long, seta it 0.061–0.063 mm long, seta db 0.098–0.10 mm long, seta der 0.20–0.23 mm long, seta dt 0.18 mm long, microsetae 0.020 mm long; all macrosetae are of the same thickness; hand with 5 dorsal and 1 ventral lyrifissure; lyrifissure lb present. Fixed finger with 9–10 teeth proximally reduced in size, three distal teeth larger; movable finger without an isolated subapical tooth (di), at the same level with the spinneret (cs) there is only a very small tubercle (Fig. 3F), with 7 teeth decreasing in size proximally, the four distal one larger ratio seta gl 0.56; spinneret prominent and apically rounded; raulum with 11–12 blades; serrulae interior and exterior respectively with 11 and 12 blades.

Coxal setae: pedipalpal coxa with 5 setae (including 2 on manducatory process), distal marginal seta of disk 0.15 mm long; coxa I 3 + 3 marginal microsetae, distal marginal seta 0.09 mm long; II 4 + 12–16 bipinnate coxal spines, III 4–5 + 6–7 bipinnate coxal spines and IV 6–7; intercoxal tubercle bisetose.

Pedipalp: femoral chaetotaxy 3:6:2:6;1 in (holotype the right femur has a chaetotaxy 3:6:2:6:1; in paratype the left femora has a chaetotaxy 3:6:3:5:1). Chela (Figs 3G–J) with hand weakly depressed at level of ib/ish and an abrupt slope between trichobothria ib/ish and eb; intercondylar protuberance (ip) present; chaetotaxy 4.5;3; seta ph absent, setae ih1, ih2, and ih3 approximately level with trichobothria ib/ish. Fixed chelal finger with 23–24 teeth, mostly pointed and with dental canals, decreasing in size proximally, 1 distal

Fig. 3. *Ephippiochthonius tauroscythicus* sp.n. 2 holotype and paratype: A — holotype, carapace, dorsal view; B — holotype, anterior margin of carapace; C — paratype, anterior margin of carapace; D — holotype, left chelicera; E — holotype, fixed finger of left chelicera, partial view; F — holotype, movable finger of left chelicera, partial view; G — holotype, left chela, dorsal view; H — holotype, left chela, lateral view; I — holotype, distal part of movable finger of left chela; J — holotype, distal part of fixed finger of left chela. Scale bars: 0.1 mm.

Рис. 3. *Ephippiochthonius tauroscythicus* sp.n. 2 голотип и паратип: A — голотип, карапакс, вид сверху; B — голотип, передний край карапакса; C — паратип, передний край карапакса; D — голотип, левая хелицера; E — голотип, неподвижный палец левой хелицеры, часть; F — голотип, подвижный палец левой хелицеры, часть; G — голотип, левая хела, вид сверху; H — голотип, левая хела, вид сбоку; I — голотип, дистальная часть подвижного пальца левой хелы; J — голотип, дистальная часть неподвижного пальца левой хелы. Масштаб: 0,1 мм.
tooth noticeably smaller than the second one, dental row almost reaching distal of trichobothrium b; base of fixed finger with 2–3 microtubercles; tip of fixed finger with a modified accessory tooth (td) on antiaxial face; one pair of long antiaxial sensory setae (as) at the finger base, distance between them longer than finger depth at base; fixed chelal finger at level of est-it with 3 teeth occupying 0.1 mm (distance between successive apices 0.040–0.045 mm). Distal half of movable chelal finger with 8–9 pointed teeth with dental canals, subdiscal tooth absent, proximal half of dental lamina smooth, without dental canals, dental row reaching halfway between trichobothria st and sb; basal apodeme long and apically indented; coupled sensilla pc well distal of sb. Trichobothria as in Figs 3G, H, trichobothrium ist level with esb (esb is slightly distal of ist) and well proximad of lyrifissures fb; distance between st and sb 1.68 times longer than that between sb and b. Chelal lyrifissure patterns hp, ha, fb, fa, fd, fb, fd, ma, ma present.

Measurements and ratios. ♀ holotype (♀ paratype in square brackets): Body 1.97 [1.97]. Carapace 0.55/0.54 (1.01) [0.56/0.55 (1.01)]. Chelicera 0.52/0.27 (2.0) [0.52/0.26 (2.0)], movable finger 0.26 [0.26]. Pedipalp: femur 0.84/0.14 (6.0) [0.90/0.14 (6.42)], patella 0.32/0.15 (2.13) [0.32/0.16 (2.0)], chela 1.31/0.23 (5.69) [1.30/0.25 (5.20)], hand 0.57 [0.55], movable finger 0.74 [0.75]; ratio movable finger/hand 1.30 [1.36], femur/movable finger 1.14 [1.20].

REMARKS. The new species is ascribed to the genus *Ephippiochthonius* on the basis of the following features: chela lagyniform (ephippiochthonian), seta hp, in the proximal portion of chelal hand absent, medial protuberance (ip) present between chelal condyles. The new species belongs to the tetrachelatus-group as defined by Gardini [2013] and Zaragoza [2017] by having the the teeth of the fixed chelal finger present nearly to the base of the finger, the movable chelal finger with low, rounded, sometimes vestigial teeth, without a marginal lamina, intermediate paraxial setae hi1, hi3 and hid of chelal hand level with trichobothria ibisibh, movable chelal finger with lyrifissure ma2. Within the tetrachelatus-group, the new species is closest to *E. conjii* Beier, 1953 from Italy: Liguria, Sicily, Sardinia; the Maltese Archipelago [Gardini, 2013] and *E. pilginjskii* sp.n. [this study].

It differs from *E. conjii* in more torglomorph features of the structure of chela, basal lamina of movable chelal finger smooth, the teeth of the movable chelal finger reach about the middle of the distance between sb-st, esb located slightly in front of the ist, the distance between the anterior and posterior eyes is noticeably larger.

A number of features that characterize the new species such as coupled sensilla pc well distal of sb, length of chela 1.30–1.31 mm, ratio movable finger/hand 1.30–1.36; pedipalpal femur/movable finger 1.14–1.20, pedipalpal femur/carapace 1.53–1.61 fall within the limits of the features defined by Gardini [2008, 2013] for *E. conjii* from some caves in Sardinia. It is worth noting that “he emphasized that shortage of specimens from populations of isolated karstic systems, showing different degrees of torglomorph, makes impossible a reliable valuation of their taxonomic status: Sardinian specimens from Nuxis are identical to those from western Liguria, whereas specimens from the caves of Armungia and Ulassai show different degrees of torglomorph specialization (see Gardini [2008], table 2)”, this means that it hides a complex of species.

In our opinion, the indicated features similar for *E. tauroscythicus* sp.n. and *E. conjii* from caves in Sardinia are not sufficient grounds to consider them as one species. The presence of the above mentioned morphological differences between *E. tauroscythicus* sp.n. and *E. conjii*, as well as their geographical distance of their ranges, indicate the independence of the described species.

*E. tauroscythicus* sp.n. differs from *E. pilginjskii* sp.n. in slightly larger size of chela and pedipalpal femur, larger ratios of pedipalpal femur/carapace and chela/carapace, a large number of teeth on the movable and fixed chelal fingers, a smaller distance between st and sb relative to the distance between sb and b, the location of ist relative to esb (esb is slightly distal of ist), the teeth of the movable chelal finger approximately reach the middle of the distance between sb-st, a large distance between sensory setae (as) relative to the depth of the fixed finger.

The new species is also notable for the variability in the pedipalpal femur chaetotaxy – one of them (but not both) may have an additional seta located either on the posterior dorsal row or on the lateral row. Median and anterior dorsal row have a constant number of seta, the ventral setae is also always one. The observed variability makes the pedipalpal femur chaetotaxy a conditional taxonomic feature at the species level. It is required a more detailed study of this variability based on more material.

*Ephippiochthonius volkeri* sp.n.

**Fig. 4.**

**HOLOTYPE** (♂ ZMUM TI-63) Crimean Peninsula, region of Sevastopol, Mt. Syundyrlyu-Kayasy, Syundyrlyu-Kobasy (= Syundyrlyu) Cave, 5 October 2016, leg. I.S. Turbanov.

**PARATYPE:** 1 ♀ (IT), 1 ♀ (ZMUM TI-64), same cave, date and collector, together with holotype.

**DISTRIBUTION.** Known from the type locality so far.

**NAME.** Named after the late Dr. Volker Mahner (1943–2018) — director of the Museum d’Histoire naturelle, Geneva, arachnologist, entomologist and ichthyologist who helped the authors at the initial stage of the exploration and study of false scorpions.

**DIAGNOSIS** (♂). A small epigean *Ephippiochthonius* that differs from other species of the tetrachelatus-group in the following combination of characters: two pairs of eyes with lens; movable cheliceral finger without a small isolated subapical tooth (di); spinneret (cs) present; carapace with a short epistome; lateral ocular setae 1.5 times longer than the sublateral ones and approximately equal in length to anterolateral setae; posteralateral seta (pl) of carapace absent; pedipalpal hand (in lateral view) with weak depression at level of ibisibh and an abrupt slope between trichobothria ibisibh and eb; fixed and movable chelal fingers respectively with 14–17 and 5–6 triangular teeth; fixed chelal finger at level of est-it with 5–6 teeth occupying 0.1 mm (distance between successive apices 0.020–0.025 mm); proximal half of movable chelal finger with 2–3 low vestigial teeth without dental canals, not reaching trichobothrium sb; sensilla pc well distal of sb; trichobothrium ist level with esb (ist slightly distal of esb) and well proximad of lyrifissures fb; length of chela 0.58–0.61 mm, length of movable chelal finger 0.34–0.36 mm; chela 4.69–4.83 times as long as deep; ratio of pedipalpal femur/carapace 1.20–1.21.

**Description of adults** (♂, ♀). Small epigean species. Integument pigmented; marked hispid granulation on lateral surfaces of carapace, on cheliceral hand and on base of chelal fingers.

Carapace slightly longer than broad and weakly constricted posteriorly; anterior margin (Figs 4A–D) strongly

Масштаб: 0,1 мм.
dentate between median macrosetae, with short epistome; ocular area as in Figs 4A, C, anterior eyes with strongly convex lens (diameter 0.030–0.038 mm), posterior eyes with flat lenses (diameter 0.030–0.036 mm), all eyes with tape-
tum; distance from anterior eyes to anterior margin of cara-
pace 0.030 mm; the distance between the anterior and poste-
rior eyes 0.030 mm. Chaetotaxy: 18 macrosetae and 2 pro-
cedular macrosetae (m) on each side, posterior area with 2
large mediocuticular (pm), posterolateral seta (pl) absent, mac-
rosetae thin; setal formula: mm4m:6:4:2:2, anteralong setae
0.070 mm long, sublateral ocular setae 0.040–0.045
mm long, lateral ocular setae 0.060 mm long; 4 lyrifissures
anteriorly and 2 posteriorly.

Chaetotaxy of tergites: 4:4:4:4:6:6:6:1TT1:4:1TT1:0. Chaetotaxy of sternites: ½ (3)(3)(2)(2):6m:6m:4m:
m:4m:6m:6:2TT1:2:0, lateral setae on sternites III–VII mi-
crosetal in size, sternite X with 2 submedielllllal tactile setae,
genital notch of c (Fig. 4H) flanked by 7–8 setae on each
side and 4+4 internal glandular tubes.

Chelicera (Figs 4E–G) with 6 setae and 2 lateral mi-
crosetae; seta vb 0.024–0.030 mm long, seta ir 0.031–0.036
mm long, seta db 0.050 mm long, seta dst 0.090 mm long, seta
dt 0.11 mm long, microsetae 0.014–0.020 mm long; all
macrosetae are about the same thickness; hand with 5 dorsal
and 1 ventral lyrifissure, lyrifissure ldb present. Fixed finger
with 5–6 teeth proximally reduced in size, two or three distal
teeth larger than others; movable finger without an isolated
subapical tooth (di), with 4–5 teeth decreasing in size proxi-
mally, one or two distal teeth larger than others (sometimes
two distal teeth are paired (Fig. 4G)); ratio seta gl 0.60;
spinneret (cs) prominent and apically rounded; raulum with
11 blades; serrulae interior and exterior respectively with 12
and 14 blades.

Coxal setae: pedipalpal coxa with 5 setae (including 2
on manducatory process), distal marginal seta of disk 0.08
mm long; coxa I 3 + 3 marginal microsetae, distal marginal
seta 0.061 mm long; II 4 + 6–7 bipinnate coxal spines, III 5 +
3 bipinnate coxal spines and IV 6; intercoxal tubercle bise-
tose.

Pedipalp: femoral chaetotaxy 3:6:2:5:1. Chela (Figs 4I–
L) with hand weakly depressed at level of ib/ib and an
abrupt slope between trichobothria ib/ib and eb; intercondi-
tlar protuberance (ip) present; chaetotaxy 4:5:3; seta ph,
lacking, setae ih, ih, and ih, approximately level with tri-
chobothria ib/ib. Fixed finger with 14–17 teeth, mostly
pointed and with dental canals, decreasing in size proximal-
ly, 1 distal tooth is noticeably smaller than the second,
short row almost reaching distal of trichobothrium b or a
little shorter, base of fixed finger with 1–2 microtubercles;
tip of fixed finger with a modified accessory tooth (td)
and antical face; one pair of long antiallelal sensory setae (as)
at the finger base, distance between them shorter than finger
depth at base; fixed chelal finger at level of est-it with 5–6
teeth occupying 0.1 mm (distance between successive apices
0.020–0.025 mm). Tip of fixed chelal finger of male with a
deep hollow on paraxial face and subapical protuberance
(sp). Distal half of movable chelal finger with 5–6 pointed
teeth with dental canals, subdistal tooth very small, proximal
half of dental lamina with 2–3 low vestigial teeth without
dental canals, not reaching trichobothrium sb; basal apodeme
long and apically indented; coupled sensilla pc well distal of
sb in both sexes. Trichobothria as in Figs 4I–L, trichobo-
thrium ist level with esb (ist is slightly distal of esb) and well
proximal of lyrifissures fb; distance between st and sb 2.10
times longer that between sb and b. Chelal lyrifissure
patterns hp, hd, fd, fa, fd, fd, fd, ma, ma, ma, present.

Measurements and ratios. holotype (C paratype in
square brackets): Body 1.19 [1.09]. Carapace 0.35/0.34 (1.01)
[0.33/0.32 (1.01)]. Chelicera 0.30/0.15 (2.0) [0.27/0.13
(2.07)]; movable finger 0.15 [0.13]. Pedipalp: femur 0.42/
0.09 (4.66) [0.40/0.08 (5.0)]; patella 0.19/0.10 (1.90) [0.17/
0.09 (1.88)]; chela 0.61/0.13 (4.69) [0.58/0.12 (4.83)]; hand
0.30 [0.28], movable finger 0.36 [0.34]; ratio movable finger/
hand 1.20 [1.21], femur/movable finger 1.16 [1.17],
femur/carapace 1.20 [1.21], chela/carapace 1.74 [1.75], che-
la/femur 1.45 [1.45].

REMARKS. The new species is ascribed to the genus
Ephippiochthonius on the basis of the following features:
chela lagyniform (ephippiochthonian), seta hp, in the prox-
imal portion of chelal hand absent, medial protuberance (ip)
present between chelal condyles, tip of fixed chelal finger of
male with a deep hollow on paraxial face and subapical
protuberance (sp). The new species belongs to the tetrache-
latus-group as defined by Gardini [2013] and Zaragoza [2017]
by having the chelal teeth of the fixed finger present nearly
to the base of the finger, movable chelal finger with low,
rounded, sometimes vestigial teeth, without a marginal lam-
ina, intermediate paraxial setae hi, hi, and hi, of chelal hand;
level with trichobothria ib/ib, chelal lyrifissure ma, present.
Within the tetrachelatus-group, the new species is morpho-
logically close to E. tetrachelatus (Preysler, 1970). It dif-
sers from E. tetrachelatus in its smaller size, the position of
the ist relative to the isb, the coupled sensilla pc well distal of
sb (in both sexes), and the presence of 2–3 low vestigial
orth on the proximal part of the movable chelal finger.
The epigean morphology of the described species found in
Syundurylu–Kobasy (= Syundurylu) Cave indicates its
possible troglobene or at maximum subtroglophilic charac-
ter. Most likely, this species is an inhabitant of the forest
floor, and it got into the cave by accident, as it was found in
the nearer (entrance) part of the cave, in the zone where
sunlight penetrates (see Fig. 1B). To clarify this assumption,
it is necessary to collect forest litter and soil on the surface
near the cave.

Ephippiochthonius pliginskii sp.n.

HOLOTYPE C (ZISP 382) Crimean Peninsula, Simferopol
Dist., env. of Perevalnoye Vill., W slope of Dolgorukovskaya
Yaya, Kizil-Koba (= Krasnaya) Cave, 7 June 1913, leg. V.G. Pliginsky.

DISTRIBUTION. Known from the type locality so far.

NAME. Named after Vladimir G. Pliginsky (1884–?) —
A Russian and Soviet entomologist, the pioneer of biospe-
ological researchers in the caves of the Crimea; the collector
of the described new species.

DIAGNOSIS (C, ? unknown). A large hypogean Ehipp-
iochthonius that differs from other species of the tetrache-
latus-group with the following combination of characters:
anterior eyes with convex lens, posterior eyes reduced to a
smooth cuticular area; movable cheliceral finger without a
small isolated subapical tooth (di); spinneret (cs) almost
absent in male; carapace without the epistome; anteralong
setae 1.4 times longer than sublateral ocular setae; postero-

200
I.S. Turbanov, V.B. Kolesnikov
Three new hypogean species of the false scorpions genus *Ephippiochthonius* from the Crimea

Fig. 5. *Ephippiochthonius pliginskyi* sp.n. ♀ holotype: A — carapace, dorsal view; B — anterior margin of carapace; C — right chelicera; D — male genital area; E — left chela, dorsal view; F — left chela, lateral view; G — right chela, lateral view; H — right chela, dorsal view. Scale bars: 0.1 mm.

Рис. 5. *Ephippiochthonius pliginskyi* sp.n. ♀ голотип: A — панцирь, вид сверху; B — передний край карапакса; C — правая хелицера; D — генитальная область самца; E — левая хела, вид сверху; F — левая хела, вид сбоку; G — правая хела, вид сбоку; H — правая хела, вид сверху. Масштаб: 0.1 мм.
lateral seta (\(ph\)) of carapace absent; pedipalpal hand (in lateral view) with weak depression at the level of \(ib/isb\) and an abrupt slope between trichobothria \(ib/isb\) and \(eb\); fixed and movable chelal fingers respectively with 17–18 and 6–7 triangular teeth; fixed chelal finger at level of \(est-it\) with 3 teeth occupying 0.1 mm (distance between successive apices 0.045 mm); proximal half of movable chelal finger smooth, without dental canals; sensilla \(pc\) well distal of \(sb\); trichobothrium \(ist\) level with \(esb\) (\(ist\) is slightly distal of \(esb\)) and well proximal of lyrifissures \(fb\); length of chela 1.07 mm, length of movable chelal finger 0.66 mm; chela 5.35 times as long as deep; ratio of pedipalpal femur/carapace 1.45.

Description of adults (\(C\), \(S\) unknown). Large, hypogean, moderately troglocenomorphic species. Integument depigmented; weakly hirsute granulation on lateral surfaces of carapace, carapace, on cheliceral hand on base of chelal fingers.

Carapace slightly longer than broad and weakly constricted posteriorly; anterior margin (Figs 5A, B) closely dentate between median macrosetae, without epistem; ocular area as in Figs 5A, anterior eyes with convex lens (diameter 0.040 mm), posterior eyes reduced to a smooth cuticular area (diameter 0.030 mm), all eyes with tapetum; distance from anterior eyes to anterior margin of carapace 0.050 mm; the distance between the anterior and posterior eyes 0.050 mm. Chaetotaxy: 18 macrosetae and 2 preocular microsetae (m) on each side, posterior area with 2 medial macrosetae (pm), posteralateral seta (pl) absent, macrosetae thin; setal formula: mm4mm:6:4;2:2, anteromedial setae 0.13 mm long, anterolateral setae 0.11 mm long, sublateral ocular setae 0.08 mm long; 4 lyrifissures anteriorly and 2 posteriorly.

Chaetotaxy of tergites: 4:4:4:6:6:6:1:2 T1 T2 4:1:2 1:0.

Chaetotaxy of sternites: 10(3)10(3):(2)(7)(2): m6m: m6m5m6m:6:2 T1 T2:0:2, lateral setae on sternites III–VII microsetal in size, sternite X with 2 submedial tactile setae, genital notch of \(C\) (Fig. 5D) flanked by 8–9 setae on each side and 4+4 internal glandular tubes.

Chelicera (Figs 5C) with 6 setae and 2 lateral macrosetae on hand; seta \(vb\) 0.060 mm long, seta \(it\) 0.065 mm long, seta \(db\) 0.080 mm long, seta \(d\) 0.184 mm long, seta \(dt\) 0.160 mm long, microsetae 0.020 mm long; all macrosetae are about the same thickness; hand with 5 dorsal and 1 ventral lyrifissure, lyrifissure \(ldb\) present. Fixed finger with 8 teeth proximally reduced in size, three distal teeth larger than others; movable finger without an isolated subapical tooth (\(dt\)), with 8 teeth decreasing in size proximally, four distal teeth larger than others; ratio seta \(gd\) 0.55; spinneret (cx) almost absent in male (Fig. 5C); rallum with 11–12 blades; serrulae interior and exterior respectively with 11 and 12 blades.

Coxal setae: pedipalpal coxa with 5 setae (including 2 on manducatory process); distal marginal seta of disk 0.14 mm long; coxa 1 3 ± 3 marginal microsetae, distal marginal seta 0.07 mm long; II 4 + 8–10 bipinnate coxal spines, III 6 + 6–7 bipinnate coxal spines and IV 6; intercoxal tubercle bisetose.

Pedipalp: femoral chaetotaxy 3:6:2:5:1. Chela (Figs 5E–H) with hand weakly depressed at level of \(ib/isb\) and an abrupt slope between trichobothria \(ib/isb\) and \(eb\); intercondi- lar protuberance (\(ip\)) present; chaetotaxy 4:5:3; seta \(ph\) lacking, setae \(ih1\), \(ih2\) and \(ih3\), approximately level with trichobothria \(ib/isb\). Fixed finger with 17–18 teeth, mostly pointed and with dental canals, decreasing in size proximally, 1 distal tooth is noticeably smaller than the second, dental row reaching slightly proximally of trichobothrium \(sb\); base of fixed finger with 3–4 microtubercles; tip of fixed finger with a modified accessory tooth (\(td\)) on antiauxial face; one pair of long antiauxial sensory setae (\(as\)) at the finger base, distance between them shorter than finger depth at base; fixed chelal finger at level of \(est-it\) with 3 teeth occupying 0.1 mm (distance between successive apices 0.045 mm). Tip of fixed chelal finger of male with a deep hollow on paraxial face and subapical protuberance (\(sp\)). Distal half of movable chelal finger with 6–7 pointed teeth with dental canals, subdistal tooth absent, proximal half of dental lamina smooth, without dental canals, dental row not reaching halfway between trichobothria \(st\) and \(sb\); basal apodeme long and apically indented; coupled sensilla \(pc\) well distal of \(sb\). Trichobothria as in Figs. 5E–H, trichobothrium \(ist\) level with \(esb\) (\(ist\) is slightly distal of \(esb\)) and well proximal of lyrifissures \(fb\); distance between \(st\) and \(sb\) 2.20 times longer than that between \(sb\) and \(h\). Chelal lyrifissure patterns \(hp\), \(hd\), \(fb\), \(fa\), \(fda\), \(fd\), \(ma\), \(ma\), present.

Measurements and ratios. \(C\) holotype: Body 2.0. Carapace 0.51/0.49 (1.04). Chelicera 0.46/0.20 (2.3), movable finger 0.23. Pedipalp: \(fb\) 0.74/0.11 (6.70), \(pta\) 0.31/ 0.14 (2.20), chela 1.07/0.20 (5.35), hand 0.49, movable finger 0.66; ratio movable finger/hand 1.35, femur/movable finger 1.12, \(femur/carapace\) 1.45, chela/carapace 2.09, chela/femur 1.45.

REMARKS. The new species is described to the genus Ephihippochthonius on the basis of the following features: chela lagyniform (ephippichthonian), setae \(hp3\) in the proximal portion of chelal hand absent, medial protuberance (\(ip\)) present between chelal condyles, tip of fixed chelal finger of male with a deep hollow on paraxial face and subapical protuberance (\(sp\)). The new species belongs to the tetrachelatus-group as defined by Gardini [2013] and Zaragoza [2017] by having the chelal teeth of the fixed finger present nearly to the base of the finger, the movable chelal finger with low, rounded, sometimes vestigial teeth, without a marginal lamina, intermediate paraxial setae \(hi1\), \(hi3\) and \(hi4\) of chelal hand level with trichobothria \(ib/isb\), chelal lyrifissure \(ma2\) present. Within the tetrachelatus-group, the new species is morphologically close \(E. tauroscythicus\) sp.n. and \(E. concii\) from Italy. The new species differs from \(E. tauroscythicus\) sp.n. in a slightly smaller size of chela and pedipalpal femur, smaller ratios of pedipalpal femur/carapace and chela/carapace, a smaller number of teeth on the movable and fixed chelal fingers, a larger distance between \(st\) and \(sb\) relative to the distance between \(sb\) and \(h\), the location of \(ist\) relative to \(esb\) (\(ist\) is slightly distal of \(esb\)), the teeth of the movable chelal finger are far from reaching the middle of the distance between \(sb\)-\(st\), a smaller distance between sensory setae (\(as\)) relative to the depth of the fixed finger. From \(E. concii\) it differs in a smooth part of lamina basalis on movable chelal finger, distal location coupled sensilla \(pc\) regarding \(sb\), a large distance between the anterior and posterior eyes, a smaller distance between the sensory setae (\(as\)).

The specimen, on the basis of which the species is described, was previously identified by V.V. Redikorzev as Chthonius tetrachelatus (Preyssler, 1790) (= \(E. tetrachelatus\)) [see Pliginsky, 1927]. However, there is no doubt that this species belongs to the tetrachelatus-group, but not to species of \(E. tetrachelatus\) sensu Gardini [2009], as indicated by a number of features: size and proportions, the structure of the ocular area, chelicera and chela. Earlier, from the same cave — Kizil-Koba (= Krasnaya), \(O. abelliei\) was quoted [Lebedinsky, 1904], assigned by V.V. Redikorzev to Ch. tetrachelatus [Pliginsky, 1927]. At the moment, this specimen is untraceable, but according to J. Lebedinsky’s
For the described species of the genus *Ephippiochthonius* from the Crimea, the distal location of coupled sensilla *pc* relative to trichobothria *sb* was observed. In his key, Zaragoza [2017] indicates the location of the *pc* relative to the *sb* as a supraspecific feature for taxonomy. Gardini [2008, 2013] notes intraspecific variation position bristles for some species (e.g., *E. gestroi* (Simon, 1896), *E. troglophilus* (Beier, 1930), *E. zoiai* (Gardini, 1990) and *E. siculus* (Beier, 1961)), however, in these cases the *pc* does not go beyond the *sb* (the exception is *E. siculus*, in females the *pc* is slightly distal than the *sb*). In *E. pliginskyi* sp.n. described by us, the distance between *sb* and *pc* on the left and right chelae of one instance may vary within 0.06–0.1 mm, but the *pc* on both chelae is located more distal than *sb*. In our opinion, it is worth paying attention to the position of the *pc* relative to the *sb* when determining the characteristics of the species; however, more material is needed for a better understanding of the taxonomic meaning of this character.

*E. tauroscyticus* sp.n. and *E. pliginskyi* sp.n. have a morphology close to troglomorphic: large body size (1.97 and 2.0, respectively), long pedipalp femur (ratio femur/carapace 1.53–1.61 and 1.45, respectively), long hela (ratio chela/carapace 2.32–2.38 and 2.09, respectively), long helal finger (ratio movable finger/hand 1.30–1.36 and 1.35, respectively), reduced posterior eyes. At the same time, both of these species have well-developed anterior eyes. These species can be considered as neotroglobionts that settled hypogean biotopes on the territory of the Crimean Peninsula in the Late Pleistocene due to global climatic changes, i.e. the alternation of glacial and interglacial periods [Jeannel, 1959; Vandel, 1964]. According to our earlier studies [Dashdamirov & Schawaller, 1993] and other researchers [Gabbutt & Vachon, 1963], the current distribution of *E. siculus* is defined as the eastern Alps and the Carpathians // Zootaxa. Vol.3655. No.1. P.1–151. http://dx.doi.org/10.11646/zootaxa.3655.1.1

Thus, the obtained results significantly supplement the available data on hypogean fauna and expand the knowledge about the false scorpions of the Crimea as a region of the Eastern Mediterranean with a rich biodiversity.

### Acknowledgments

Our deep gratitude goes to Kirill G. Mikhailov (ZMUM, Moscow) and Viktor A. Krivokhatsky (ZISP, Saint Petersburg) for possibility deposited and study types materials in the museum collections under their care. We thank Natalia V. Ashchepekova (Civo SO, Italy) for improving the English language of the manuscript. Thanks are also due to Giulio Gardini (University of Genoa, Italy) and Srečko Ćurčič (University of Belgrade, Serbia) for bibliographic assistance. We express our gratitude to the reviewers, G. Gardini and Alexander G. Koval (All-Russian Institute of Plant Protection (VIZR), Saint Petersburg – Pushkin), for valuable remarks and comments that significantly improved this publication. A special thank to our crimean friends, speleologists Sergey V. Arelyev and Sergey N. Bagach (Sevastopol) for providing fotos of the cave biotopes. This study by Ilya S. Turbanov was performed in the framework of the state assignment (topics No. 1818118012690105-0, 118012690106-7).
