Abstract—3D object proposals, quickly detected regions in a 3D scene that likely contain an object of interest, are an effective approach to improve the computational efficiency and accuracy of the object detection framework. In this work, we propose a novel online method that uses our previously developed 3D object proposals, in a RGB-D video sequence, to match and track static objects in the scene using shape matching. Our main observation is that depth images provide important information about the geometry of the scene that is often ignored in object matching techniques. Our method takes less than a second in MATLAB on a single thread CPU and thus, has potential to be used in low-power chips in Unmanned Aerial Vehicles (UAVs), quadcopters, and drones.

I. INTRODUCTION

The rapid development of low-powered Unmanned Aerial Vehicles (UAVs), drones and service robots has introduced a need for automatic detection of interesting objects present in a scene. Such applications may not only assist in navigation of these devices but also help in localizing, tracking and identifying the objects that are present in a scene. This paper presents a framework where we leverage on color and depth information, per frame, to obtain a global heatmap of the scene. This heatmap is used to find interesting 3D objects in the scene. Using RGB-D SLAM enables us to locate these 3D objects in the scene. We use Jaccard index to match objects in the scene. We show that using a simple Intersection over Union (IoU) is much faster than using complex techniques such as 3D feature matching for static objects in the scene, while maintaining similar accuracy.

The popularity of depth cameras in scientific community has led to explosion of recent discoveries of various applications in computer and robot vision [6]–[10], including object recognition [11]. While 3D object proposals are a relatively new idea [1], they are heavily inspired from 2D object proposals [2]–[5]. 2D object proposal techniques have become immensely popular in object detection systems. Instead of finding precise and exclusive boundaries for objects, modern 2D object proposal techniques quickly identify regions (potentially highly overlapped) that are very likely to contain an object. 3D object proposals build on this idea. An effective way to obtain true shape, size, and orientation of 3D objects is to use depth cameras. 3D object proposals utilize depth information to estimate scene geometry and use the additional information to extend the 2D objects proposals to 3D by estimating 3D cuboids for each object on interest. 3D proposals are inherently more useful than 2D object proposals as they provide us with accurate physical dimensions of the objects of interest that are present in the scene which can be used for various tasks such as object manipulation and scene understanding.

In this work, we utilize online 3D object proposals for RGB-D video input of a static scene with the main focus on matching objects. We use the results obtained per-frame by existing 3D proposal techniques as an input to our system. We leverage on segmentation cues provided by depth information and aggregate them over consecutive frames in 3D by estimating the camera poses using RGB-D SLAM. This enables us to obtain accurate 3D boundaries of the objects of interest in the scene and use these boundaries as cues to match objects in the scene.

More specifically, this work focuses on indoor, static scenes containing a major supporting plane. However, it can be easily extended to multiple supporting planes. The objects are allowed to occlude each other and partially seen in some images as long as their complete view is covered over a consecutive number of frames. Note that we do not assume their distance to the camera. We make the following contributions:

- We use the camera pose estimated by a depth based SLAM technique to efficiently register the frames to a global point cloud. We constantly update our global 3D object proposals as the camera moves around in the scene.
- We match the current frame’s 3D object proposals to global 3D object proposals using shape matching to find matching objects in the scene. Any new object seen is added to the global object dataset and tracked from thereon.

Our paper is structured as follows. In Section [II] we review other works that are related to our research topic. In Section [III] we provide a brief overview of 3D object proposals. Section [IV] presents the proposed 3D shape matching steps in detail, highlighting our contributions and observations at each stage. We report our results in Section [V]. Finally, in Section [VI] we conclude this paper and discuss future research directions.

II. RELATED WORK

Object proposals: A lot of work has been done recently on 2D object proposals. Traditionally, sliding windows are used.
III. 3D OBJECT PROPOSALS

We start by giving an overview of the 3D object proposals technique [1]. At high level, the algorithm is designed to fuse the depth information with the generic 2D object proposals obtained from color images to obtain 3D object proposals per frame. This enables us to exploit using 3D geometry of the scene. These object proposals are improved as the camera moves around in the scene. Figure 1 illustrates the basic setup of the problem and an example result obtained.

Before presenting the main components of our approach, we first introduce the initialization process with 3D object proposals. We collect \( N \) video frames per scene using a RGBD camera. Every \( i \)th video frame consists of a color image \( I_i \), a depth image \( Z_i \), and the pose of the camera \( P_i \), using a depth based SLAM method such as Dense Visual SLAM [21]. The camera pose contains the rotation and translation measurements of the camera in the world coordinate frame of reference: \( P_i = [R_i, t_i] \). The RGB-D camera is assumed to be pre-calibrated. The camera intrinsic parameters - the focal length in \( x \) and \( y \) directions and optical center are denoted by \( f_x, f_y, [c_x, c_y] \), respectively. Together, these are represented by the intrinsic calibration matrix \( K \). We use a generic 3D object proposal technique [1] to obtain \( M \) 3D object proposals per frame:

\[
BB_j = [x^j, y^j, z^j, l^j, w^j, h^j], \quad j = 1, \ldots, M, \quad (1)
\]

\[
r^j = [r^j_x, r^j_y, r^j_z]^T, \quad (2)
\]

where, \([x, y, z]\) denote the top-left 3D coordinate of the bounding box, and \( l, w, \) and \( h \) refer to the length, width and the height in \( x, y \) and \( z \) directions respectively. \( r \) refers to the rotation of the bounding box to align it to the horizontal direction of the scene so that the bounding boxes “rest” on the underlying planes such as table and floor. A few 3D proposals are shown in Fig. 1. These 3D object proposals per image are treated as an input for our framework. Thus, the dimensionality of our feature descriptor is only of size nine which makes our shape matching extremely fast.

IV. SHAPE MATCHING USING 3D OBJECT PROPOSALS

In this section, we describe how we use 3D object proposals to identify and label 3D objects in the scene using shape matching.

Let us assume that we obtain \( M \) 3D objects after processing first frame in a given scene using [1]. These objects are labelled sequentially from 1 to \( M \). After each frame, we update the 3D heatmap of the scene as shown in Fig. 2. Every frame update provides us with two new heatmaps - an updated global heatmap and the current frame’s heatmap. We use the current heatmap to estimate the 3D boundaries of objects present in the current frame. As we estimate the camera per frame using RGB-D SLAM, we can transform these object boundaries to the first frame of reference. These object boundaries are compared with the existing database of object boundaries present in the scene. If the new object boundary overlaps significantly with an existing object, it is
considered as the same object seen previously and assigned the corresponding label. However, if the object boundary does not overlap with any current existing objects in the scene, it is considered a new object and assigned a new label and added to the existing object database. We use Intersection over Union (IoU) in 3D to find the overlap value of the \( i \)th current 3D object proposal as follows:

\[
\text{IoU}(i) = \max_j \left( \frac{\text{BB}_i(i) \cap \text{BB}_j(j)}{\text{BB}_i(i) \cup \text{BB}_j(j)} \right) \quad \forall j \in 1, \ldots, M (3)
\]

where \( \text{BB}_i(i) \) refers to the \( i \)th 3D bounding box of the current frame’s 3D object proposal and \( \text{BB}_j(j) \) refers to the \( j \)th 3D bounding box of the existing objects in the scene. The intersection and union in 3D are computed similar to their corresponding 2D versions as:

\[
x^i \cap x^j = \begin{cases} 
0 & \text{if } x^i + l^i < x^j \text{ or } x^j + l^j < x^i \\
\max(x^i + l^i - x^j, x^j + l^j - x^i) & \text{otherwise},
\end{cases}
\]

(4)

\[
x^i \cup x^j = \begin{cases} 
l^i + l^j & \text{if } x^i + l^i < x^j \text{ or } x^j + l^j < x^i \\
l^i + l^j - (x^i \cap x^j) & \text{otherwise},
\end{cases}
\]

(5)

\[
\text{BB}(i) \cap \text{BB}(j) = |x^i \cap x^j|, |y^i \cap y^j|, |z^i \cap z^j| \quad (6)
\]

\[
\text{BB}(i) \cup \text{BB}(j) = |x^i \cup x^j|, |y^i \cup y^j|, |z^i \cup z^j| \quad (7)
\]

There are various benefits of using shape matching. It is extremely fast as we only need to compute the 3D boundaries of objects. The IoU can be computed in \( O(M) \), where \( M \) is the number of existing objects in the scene. Moreover, we use the actual position of the objects in the scene. If an object is occluded by another object temporarily and seen later, it is immediately re-identified as the original object and assigned the same label as previously. Using 3D feature matching is slow and sensitive to conditions such as lighting and camera orientation. Meanwhile, shape matching overcomes these issues as it relies on the 3D pose and location of the objects in the scene.

V. RESULTS

We use UW-RGBD scene dataset \( \mathbb{D} \) to conduct our experimental analysis and evaluation. The dataset contains 14 scenes reconstructed from RGB-D video sequences containing furniture and some table-top objects such as caps, cereal boxes and coffee mugs. The scenes contain depth and color frames from a video collected by moving around the scene. The dataset provides a globally labelled 3D point cloud.

After we obtain a 3D heatmap per frame, we use multi-view information to fuse this information together. We used Dense Visual SLAM \( \mathbb{J} \) to obtain the camera pose per frame to fuse the frames together. The entire process takes 3.03s for VGA resolutions on average in MATLAB. However, a majority of the time (> 2.0s) is spent in storing and accessing the 3D point cloud. As we aim for a fast and efficient algorithm that is capable of online processing of 3D object proposals, we downsample the images by 2. This reduces the time taken per frame to less than one second in MATLAB on a single-core CPU while maintaining a similar accuracy in matching and tracking objects. We obtain on average 6.57 3D object proposals per scene. Our results can be further improved with an improved camera pose estimation, as in some cases the objects break into two or more discontinuous point clusters due to noisy camera poses. This results in multiple distinct object proposals for one object, essentially dividing the object into two or more pieces.

Figures 3 and 4 show some sample frames in the video sequence. Full videos can be accessed here. We observe that our shape matching technique is able to match static objects successfully in most occasions. The white soda can is hiding behind the cereal box and the green soda can is assigned label 5 in Fig. 3(a). Once it is seen in frame 93 in Fig. 3(b), it is assigned label 12. The green soda can is occluded by cereal box in frame 522, but as soon as it is observed again, it is reassigned the same label 5 as shown in Fig. 3(f). We observe the same behavior in Fig. 4 where the green soda can is initially hidden behind cereal box and all the objects occluded by the cereal box are identified as same objects seen before once they reappear in the scene. This shows that, for static objects, we can use an extremely fast shape matching in a RGB-D video sequence rather than expensive feature descriptors \( \mathbb{I} \) that are storage and computationally intensive.

VI. CONCLUSION

In this paper, we have used 3D object proposals to track and label objects in the scene. In future work, we aim to optimize our system towards real-time 3D object tracking over even larger environments by exploring multi-scale representations for memory and computational efficiency. Ultimately, we intend to improve the accuracy of existing SLAM techniques.
treating the detected objects as fixed landmarks in the scene. Full video can be accessed here.

by integrating our system to create a semantic SLAM by treating the detected objects as fixed landmarks in the scene.
