Abstract. A new type of maneuverable combined-cycle plant with a steam-turbine drive of a low-pressure compressor is considered. The analysis of its technological processes in the generation of electric and thermal energy in heating and non-heating periods of the year is carried out. It is shown that in heating conditions, the burning of additional fuel in the afterburner between the stages of the evaporator of the utilizer boiler provides an increase in its steam production, maneuverability, thermal and electric power of the CCGT-CHP plant. The influence of the chemical composition and thermophysical properties of natural gas on obtaining the required excess air in the combustion chamber of a combined cycle gas turbine is considered. A mathematical model of technological processes is developed. The influence of deep utilization of the heat of the flue gases of the utilizer boiler on increasing the efficiency and improving the environmental characteristics of the gas-steam plant of a thermal power plant was recorded.

Key words: electric and thermal power, waste heat boiler, backpressure steam turbine, gas turbine installation, combined cycle gas turbine, compressor steam drive.

1. Introduction

One of the urgent problems of the energy sector is the creation of cogeneration CCGT-CHP with a high level of cogeneration generation of heat and electric energy [1]. To increase the thermal and electric power in the heating modes of their operation, in the patent [2] it was proposed to use a two-stage evaporator with a fuel afterburning chamber (AC) between its steps in a waste heat boiler (HB), to supply this CCGT-CHP with two counter-pressure turbines with network heaters. This allows, due to the combustion of fuel in the boiler house, to increase the production of steam in the boiler unit and significantly increase the electric and thermal power [3]. These measures contribute to improving the maneuverability of the combined cycle power plant. In the patent [4], a scheme is proposed for a gas-steam heat and power plant in which expanded steam in a counter-pressure steam turbine (ST) is mixed in the combustion chamber (CC) with the products of fuel combustion. The resulting mixture is expanded in a combined cycle gas turbine (SGT) driving an electric generator. The installation pro-
vides contact condensation of the vapor component of the gas-vapor mixture. The article [5] compares the characteristics of CCGT with steam and gas turbine drives of compressors. It was found that the steam drive helps to reduce the degree of increase in air pressure in the compressor and increase the gas temperature in front of the compressor unit. In the application for the invention [6], the authors proposed a new type of gas-steam CCGT-CHP, which has high mobility when working in both non-heating and heating periods of the year and increased thermal efficiency. CCGT-CHP (Fig. 1) contains a gas turbine unit with (gas turbine), a waste heat boiler with a two-stage evaporator and a chamber for afterburning fuel, and two counter-pressure transformer substations.

2. The principle of operation of the installation

The principle of its operation is as follows: atmospheric air is compressed in a low-pressure compressor (LPC) driven from the main counterpressure steam turbine PT1. The air is compressed in a high-pressure compressor (HPC) and then fed into the combustion chamber (CC). To increase the proportion of steam in the gas-vapor mixture, the combustion process in the CC is carried out at a small coefficient of excess air $\alpha \approx 1.2$. This ratio of fuel and air will ensure complete combustion at a low air flow through the compressor. In the mixing chamber CC serves steam expanded in PT1.

![Diagram](image-url)
The resulting gas-vapor mixture is expanded in a gas-vapor turbine (GVT). Her work is used to drive HPC and an electric generator (E). The steam-gas mixture expanded in the PGT is sent to a waste heat boiler (HB), where its heat is used: for generating superheated high-pressure steam in the economizer of the second stage (EclII), in the evaporator and steam superheater, for heating the heating network water, in gas and water heater (GWH) and for heating of feed water in the economizer of the first stage (EclI). As in [1], to increase the maneuverability of the unit during the heating period, additional fuel is burned in the fuel boiler and the steam production in the boiler is increased. This steam is fed to PT2 to increase the production of electricity and heat network water in (HNW). When the temperature of the outside air changes, the steam capacity of the HB is regulated by changing the fuel consumption in the boiler.

A feature of this scheme is the low-pressure switch from the steam turbine STI, and the high-pressure switch from the turbine. Introducing steam into the CC mixing zone allows increasing the work of expanding the gas-vapor mixture and increasing its power. HB provides for the use of heat of condensation of water vapor from a gas-vapor mixture and the return of condensate to the cycle. Its high potential heat is used to generate steam in the HB, and low potential heat is used in the hot water supply to heat the network water of the heating system.

3. Materials and Methods
Natural gas (NG) is used as a fuel for CCGT, which differs in its chemical composition in the content of hydrocarbons and other gases depending on the field. Therefore, the NG has different values of the lower heat of combustion of the fuel Hu and the stoichiometric coefficient Ls. In [7, 8], an analysis was made of the influence of the composition of the working fluid on the parameters of GTU efficiency. Failure to take into account the composition of the fuel gas for a mixture with \( \alpha=1...4 \) reduces the accuracy of engineering thermodynamic calculations, then it decreases from 7% to 3% [9]. When compiling a mathematical model for calculating the parameters of combined cycle steam turbine units with LPC steam drives, the air humidity at the inlet to the gas turbine and the humidity of the fuel gas were taken into account. The coefficient of excess air in the compressor station is determined taking into account the properties of the components of the gas mixture: air and combustion products of gaseous fuels \( N_2, CO_2, O_2, H_2O \), depending on the parameters of the gas turbine based on the heat balance equation:

\[
\alpha = \frac{\eta_{cc} \cdot H_u - h_{ncc}^* \left(1 - \frac{1}{L_s}\right) + h_{ec}^*}{h_{ncc}^* - h_{ec}^*},
\]

where: \( \eta_{cc} \) – the coefficient of completeness of fuel combustion in the CC, \( h_{ncc}^* = V^0C_p^0T_G^* \) - is the enthalpy of air at the theoretically necessary amount for combustion at a temperature \( T_G^* \) in front of the turbine, \( h_{ec}^* = \left( V_{CO_2}^0 \cdot C_p^{CO_2} + V_{N_2}^0 \cdot C_p^{N_2} + V_{H_2O}^0 \cdot C_p^{H_2O} \right) T_G^* \) is the enthalpy of the products of combustion with the coefficient of excess air \( \alpha=1 \) and temperature \( T_G^* \), \( h_{ec}^* = V^0C_p^0T_G^* \) - enthalpy of air at a theoretically necessary amount at temperature \( T_G^* \), \( C_p^{CO_2}, C_p^{N_2}, C_p^{H_2O}, C_p^* \) - mass heat capacities of carbon dioxide, nitrogen, water vapor and air, respectively, at the temperature of the combustion products \( T_G^* \) and air at the entrance to the combustion chamber \( T_G^* \); \( V_{RO_2}^0 \) - is the volume of triatomic gases of combustion products (without water vapor at \( \alpha=1 \)), \( V_{H_2O}^0 \) - is the volume of water vapor taking into account the moisture content in fuel and in air, \( V_{RO_2} \) - is the volume of diatomic gases of combustion products (without water vapor at \( \alpha=1 \)): \( V^0 = V_{RO_2}^0 + V_{RO_2} + V_{H_2O} \) - is the total volume of combustion products.
The coefficient of excess air in the combustion chamber $\alpha$ depends on the enthalpy of gas in front of the turbine $h_G$ and the enthalpy of air behind the compressor $h_C$, which is determined by the degree of increase in pressure in the compressor $\pi_C$. For the temperature range in front of the turbine from 1373 K to 1673 K, the dependence of $\alpha$ on the degree of pressure increase in the compressor $\pi_C$.

![Diagram](image)

**Figure 2.** The dependence of $\alpha$ on the degree of pressure increase in the compressor $\pi_C$.

Based on the mathematical model, a graphical dependence of the coefficient of excess air in the compressor station on the parameters of the gas turbine unit was constructed (Figure 2), which allows one to estimate the range of the choice of the degree of increase in pressure $\pi_C$ and the gas temperature in front of the turbine $T_T$ for a mixture with an excess air coefficient $\alpha \approx 1.15 \ldots 1.25$.

From the choice of the total degree of increase in pressure in the compressor $\pi_{\Sigma C} = \pi_{\Sigma PC} \cdot \pi_{\Sigma LPC}$ depends on the amount of useful work of the cycle of gas turbines $Le$ and the obtaining in the $CC$ value $\alpha$ at the level of 1.15 ... 1.25. The power consumed by the compressor $N_C$ was calculated, depending on the air flow rate $G_V$ through it at different $\pi_{\Sigma C}$. The compressor power increases with increasing $\pi_{\Sigma C}$ and the flow rate of compressed air $G_V$. The steam parameters at the $CC$ inlet are set taking into account the steam parameters in front of typical backpressure turbines and the level of hydraulic losses in the steam path. Accepted: $R_{SS} = 9.0$ to 13.0 MPa; $M_S = 818$ K; $R_{SS} = 1.6$ MPa; $T_{SS} = 513$ K.

### 4. Calculation method

Steam flow through the PT is determined by a given $G_V$ and $\pi_{LPC}$ [10, 11]. In Figure 3 shows the dependence of the relative steam flow rate through PT1 on the distribution of $\pi K$ over the compressor stages, where:

$$\frac{\pi_{LPC}}{\pi_{\Sigma C}} = \pi_{LPC}$$

(2)
Figure 3. The dependence of $q_{S.S.}$ on the relative $\pi_{LPC}$.

The use of low pressure $\pi_{LPC}$ in low pressure steam pumps allows to reduce the consumption of superheated steam and to reduce the power of the drive $PT1$ and the steam productivity of $HB$ in non-heating operating modes of the $CCGT-CHP$. The characteristics of the gas-vapor mixture in the $SGT$ and in the $HB$ — the flow rate, pressure, and enthalpies of the mixture were determined taking into account the shares of the products of combustion and steam [12]. The electric power of the gas-steam $CCGT-CHP$ in non-heating modes of its operation is determined:

$$N_{EX} = G_v \left[ (1 - q_C + q_T + q_{ST}) L_{SGT} \cdot \eta_M - L_{HPC} \right]$$

(3)

where: $L_{SGT}$ is the specific operation of a combined cycle gas turbine, $L_{HPC}$ is the specific operation of $HPC$, $\eta_M$ is the mechanical efficiency, $G_v$ is the mass flow rate of gas turbine units, $q_i$ is the relative flow rate of the working fluid (cooling air, fuel, saturated steam). Enthalpy of gas-vapor mixture at the outlet of the steam generator $HB$:

$$h_{outAB} = \frac{(1 - q_C + q_T) h_{SGT}^G - q_{ST} \cdot h_{SGT}^P}{(1 - q_C + q_T + q_{ST})}$$

(4)

where: $h_{SGT}^G$ is the enthalpy of the vapor-gas mixture, $h_{SGT}^P$ is the enthalpy of the vapor-gas mixture at the outlet of the steam section of the $HB$.

Steam production $HB$:

$$G_{FE} = \frac{(1 - q_C + q_T) h_{SGT}^G - q_{NP} \cdot h_{SGT}^P}{(h_{outAB} - h_{PV})}.$$  

(5)
In heating modes, additional fuel is burned in the boiler to increase steam production in the boiler for \( ST2 \), its operation is used to drive the electric generator. The total electric power of \( SGT \) and \( ST2 \) in heating modes of the gas-steam \( CCGT-CHP \):

\[
N_{EZ} = G_{SGmix} L_{SGT} + G_{SS} L_{ST2} - G_{V} L_{HPC};
\]

\[
L_{ST2} = (h_{SS} - h_{BP}) \eta_{SGs} \equiv \frac{G_{ST2}}{G_{V2}} L_{ST2}.
\]

where: \( L_{ST2} \) is the specific operation of the energy steam turbine, \( h_{SS} \) is the enthalpy of superheated steam, \( h_{BP} \) is the adiabatic back pressure enthalpy, and \( \eta_{STs} \) is the efficiency of the steam turbine 2.

Additional electrical power of the installation due to expansion of steam in \( ST2 \):

\[
N_{EST2} = (G_{V2} - G_{ST1}) L_{ST2}.
\]

The total electric power of gas-steam \( CCGT-CHP \) in heating modes:

\[
N_{EZ} = G_{V} \left[ (1 - q_{C} + q_{T} + q_{SS}) L_{SGT} \cdot \eta_{M} - L_{HPC} \right].
\]

Relative fuel consumption in AB:

\[
q_{fAB} = \frac{G_{fAB}}{G_{V2}} = \frac{h_{mAB}^* - h_{outAB}^* - h_{T} + h_{V}}{\eta_{AB} \cdot H - h_{T} + h_{V}},
\]

where: \( h_{mAB}^* , h_{outAB}^* \) are the enthalpies of the mixture in front of and behind the afterburner, \( G_{fAB} \) is the fuel consumption in AB. \( h_{T} \) is the enthalpy of fuel gas, \( h_{V} \) is the enthalpy of air.

Thermal power of the installation in heating conditions:

\[
Q_{\Sigma} = Q_{NW} - Q_{GWH},
\]

\[
Q_{NW} = G_{PE} \cdot r,
\]

\[
Q_{GWH} = (G_{PE} + G_{AB})(h_{2HB} - h_{CU}) \eta_{GWH}
\]

where: \( Q_{NW} \) - heat generated in the \( HNW \); - specific heat of vaporization, \( Q_{GWH} \) - thermal energy of \( GWH \).

Using the proposed mathematical model, an analysis of the characteristics of the gas-steam \( CCGT-CHPP \) was carried out during its operation in the non-heating and heating periods of the year according to recommendations [14]. In the calculations, the following were taken: air flow through compressors \( G_{A}=25 \text{ kg/s} \), the degree of increase in pressure in the low-pressure switch and in the high-pressure switch \( \pi_{SC}=6.4 \); excess air coefficient \( \alpha = 1.2 \). The temperature of the mixture before \( SGT T_{SG}=1100K \). The parameters of superheated steam produced in the \( HB - 13 \text{ MPa}, 540 \) [11]. The regulation of the characteristics of the units is carried out in accordance with the operating conditions of the \( CCGT \) unit by changing the fuel consumption in \( CC \) and \( AB \). In fig. Figures 3 and 4 show the effect of fuel consumption in \( AB \) on \( HB \) steam production and on the generation of additional electric power in \( ST2 \). The use of the afterburner with an additional fan gives a double increase in the electric capacity of the \( CCGT \) unit.
Figure 4. The dependence of the $HB$ steam productivity on the relative consumption of fuel gas in the gas compressor $G_{SS} = f(q_{tAB})$

Figure 5. The dependence of the additional electric power $N_E$ on the relative fuel consumption $q_{tAB}$ in $AB$.

5. Conclusion.
The proposed scheme of a gas-steam installation with a low-pressure steam drive with an excess air coefficient $\alpha=1.2$ in the compressor station and supplying steam from the $ST1$ to the mixing chamber makes it possible to reduce the metal consumption of the design of compressors and $ST1$ at a low level of $G_V$ and $\pi_{CC}$. The expansion of the gas-vapor mixture in the gas-turbine $SPT$ contributes to an increase in temperature before the $CC$ increases its steam production. The installation between the stages of the $KD$ evaporator with a fan for supplying air to it makes it possible to increase the combined heat and power capacity of the $CCGT$ unit with an increase in the indicators of joint cogeneration generation of heat and electric energy [15]. The technological scheme of the gas-steam $CCGT-CHP$ is relatively simple and has lower capital costs compared to a binary cycle $CCGT$. According to recommendations [16], the introduction of steam into the gas turbine combustion chamber improves the environmental performance of the $CCGT-CHP$.
