ABSTRACT:

Background: Elevated intraocular pressure (IOP) is a major risk factor for the development and progression of primary open angle glaucoma and is due to trabecular meshwork (TM) damage. Here, we investigate the role of an endogenous Toll-like receptor 4 (TLR4) ligand, FN-EDA, in the development of glaucoma utilizing a transgenic mouse strain (B6.EDA^{+/+}) that constitutively expresses only FN containing the EDA isoform.

Methods: Eyes from C57BL6/J (wild-type), B6.EDA^{+/+} (constitutively active EDA), B6.EDA^{-/-} (EDA null) mice were processed for electron microscopy and consecutive images of the entire length of the TM and Schlemm’s canal (SC) from anterior to posterior were collected and montaged into a single image. ECM accumulation, basement membrane length, and size and number of giant vacuoles were quantified by ImageJ analysis. Tlr4 and Iba1 expression in the TM and ONH cells was conducted using RNAscope in situ hybridization and immunohistochemistry protocols. IOP was measured using a rebound tonometer, ON damage assessed by PPD stain, and RGC loss quantified in RBPMS labeled retina flat mounts.

Results: Ultrastructure analyses show the TM of B6.EDA^{+/+} mice have significantly increased accumulation of ECM between TM beams with few empty spaces compared to C57BL/6J mice (P<0.05). SC basement membrane is thicker and more continuous in B6.EDA^{+/+} mice compared to C57BL/6J. No significant structural differences are detected in the TM of EDA null mice. Tlr4 and Iba1 expression is increased in the TM of B6.EDA^{+/+} mice compared to C57BL/6J eyes (p<0.05). IOP is significantly higher in B6.EDA^{+/+} mice compared to C57BL/6J eyes (p<0.001), and significant ON damage (p<0.001) and RGC loss (p<0.05) detected at one year of age. Tlr4 mRNA is expressed in mouse ONH cells, and is present in ganglion cell axons, microglia, and astrocytes. There is a significant increase in the area occupied by Iba-1 positive microglia cells in the ONH of B6.EDA^{+/+} mice compared to C57BL/6J control eyes (p<0.01).
Conclusions: B6.EDA^{+/+} mice have increased ECM accumulation in the TM, elevated IOP, enhanced proinflammatory changes in the ONH, loss of RGCs, and ONH damage. These data suggest B6.EDA^{+/+} mice recapitulate many aspects of glaucomatous damage.

Background:

Elevated intraocular pressure (IOP) is a primary risk factor for the development and progression of glaucoma. Glaucoma is characterized by cupping of the optic nerve head (ONH), thinning and loss of the retinal nerve fiber layer, and characteristic visual field defects. Primary open angle glaucoma (POAG) is the most common form of glaucoma and is characterized by elevated IOP due to increased aqueous humor outflow resistance. The majority of aqueous humor drains from the eye through the conventional outflow pathway, passing through the trabecular meshwork (TM), Schlemm’s canal (SC), and eventually into the episcleral veins. The TM and SC regions are the primary determinant and homeostatic regulator of IOP [1, 2]. The TM comprises semi-fenestrated beams of connective lamina with incorporated flat cells of neural crest origin and epithelial morphology [1]. The outer part of the TM forms the juxtacanalicular tissue (JCT) with abundant ECM, which is located adjacent to the inner wall of SC. Increased deposition of ECM proteins in the TM, as well as the stiffness of the ECM and TM cells, is believed to be the cause of increased AH outflow resistance and increased IOP associated with POAG [3, 4]. In addition, increased stiffness and changes to the underlying ECM of the inner wall of Schlemm’s canal (SC) has also been identified as a major contributing cause to ocular hypertension [2]. TM cells secrete a wide variety of ECM and metalloproteases for constant maintenance of ECM integrity [5]. Profibrotic TGFβ2 signaling is known to be involved in the damage to the ECM of the TM and the increased stiffness of the TM in glaucoma [6, 7]. Among the changes TGFβ2 signaling causes in the TM is an increased deposition of fibronectin [8], fine fibrillar material [9, 10] and altered glycosaminoglycan composition [11]. These data demonstrate that the ECM architecture of the TM is important in regulating aqueous humor outflow and IOP.

We and others have identified FN, a dimeric multidomain ECM glycoprotein, to be elevated in glaucomatous TM tissues and AH [12-15]. FN functions as a regulator of cellular
processes, directs and maintains tissue organization and ECM composition, directs ECM-ECM and ECM-cell interactions, and regulates activity of growth factors and proteins associated with ECM remodeling. The multi-domain dimer is composed of type I, type II, and type III domains with over 20 alternatively spliced isoforms. FN is composed of either cellular FN (cFN) or plasma FN (pFN) isoforms. cFN has multiple isoforms generated by alternative processing of a single primary transcript at 3 domains: extra domain A (EDA), extra domain B (EDB), and the type III homologies connecting segment [16]. During embryonic development, the fibronectin EDA (FN-EDA) isoform is abundant [17]; however, in adults the presence of FN-EDA is minimal and primarily functions as a structural scaffold and signaling molecule that regulates cell adhesion, proliferation, and migration [18]. In addition, the expression of FN-EDA is upregulated as a response to tissue injury, repair, or remodeling, and during disease states [19-22].

Previously, it has been shown that FN and the FN-EDA isoform are significantly elevated in the human glaucomatous TM [23]. In addition, we have previously shown that TGFβ2-induced ocular hypertension is dependent on both FN-EDA and its receptor toll-like receptor 4 (TLR4) [13, 24, 25]. Functionally, it is known that EDA acts as an endogenous ligand (DAMP, damage associated molecular pattern) for TLR4, eliciting similar downstream responses as LPS [26]. DAMP activated TLR4 signaling has been linked to fibrosis and the regulation and production of ECM proteins in hepatic fibrosis, renal fibrosis, lesional skin and lung in scleroderma patients, and most important to the work presented here we have linked DAMP activated TLR4 to TM damage and ocular hypertension [13, 27-30]. TLR4 activation downregulates the TGFβ antagonist, BMP and the activin membrane-bound inhibitor (BAMBI), which enhances TGFβ signaling leading to increased ECM production [27, 28] and production of DAMPs such as FN-EDA [24].

Previously, we demonstrated in primary human TM cells in culture, that inhibition of TLR4 blocks TGFβ2-induced ECM production, and FN-EDA enhanced TGFβ2-induced ECM
production [13]. In addition, we showed that mice constitutively expressing the EDA isoform develop ocular hypertension [24]. Here we show that in mice constitutively expressing FN-EDA there is greater accumulation of ECM in the TM and changes to SC basement membrane. We also show that mice constitutively expressing FN-EDA exhibit significantly elevated IOP, increased ONH microglial activation, ON damage, and loss of RGCs.

Methods:

Animals

All experiments were conducted in compliance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and approved by the University of Wisconsin-Madison Institutional Animal Care and Use Committee (IACUC) Guidelines and Regulations. The generation of B6.EDA^-/- and B6.EDA^+/+ mice has previously been described[31]. B6.EDA^+/+ mice were generated to contain spliced sites at both splicing junctions of the EDA exon and therefore constitutively express only FN containing EDA. B6.EDA^-/- mice contain an EDA-null allele of the EDA exon and express only FN lacking EDA. C57BL/6J mice were purchased from the Jackson Laboratories. All animals were housed in the UW-Madison vivarium. All mice were maintained on a normal 12-hour light/dark cycle and maintained on a 4% fat diet (Harkland Teklad, Madison, WI, USA) with food and water available ad libitum.

Ultrastructural Analysis

For ultrastructural analysis mice were euthanized by CO2 inhalation, eyes were enucleated, placed in 0.1M Sodium cacodylate buffer, and a small puncture was made in the cornea for the immediate access of fixative to the TM tissue. Eyes were then transferred into fixative (2.5% Paraformaldehyde, 2.5% Glutaraldehyde in 0.1M cacodylate buffer) and incubated at room temperature overnight on a rotator. Eyes were postfixied in a mixture of 1% OsO4, 0.8%
potassium ferrocyanide in 0.1 M cacodylate buffer for 3.5 hours at room temperature. Samples were rinsed in cacodylate buffer, followed by water, dehydrated in graded series of 35%, 50%, 60%, 70% ethanol, each time for 15 min twice. Next, samples were stained in 2% uranyl acetate in 70% ethanol for 2 hours, rinsed in 70% ethanol overnight, followed by 80%, 90%, 95%, 100% ethanol each time for 15 min twice. Samples were further dehydrated in mixture of 1/1 Ethanol/Acetone, followed by two rinses in 100 % acetone for 15 minutes each. Further, samples were embedded into graded mixtures of 3/1, 1/1, 1/3 Acetone/EPON for 12 hours each, followed by two changes of pure EPON for 24 hours each time. In order to remove residual water, samples were placed into a vacuum for 1 hour, and polymerized in EPON at 60 degrees Celsius for 24 hours. After polymerization, ultrathin sections (80 nm thin) were cut and placed on formvar coated slot grids, poststained with uranyl acetate and lead citrate. Images were taken using a Philips Electron Microscope. Consecutive images of entire length of TM and SC area from anterior to posterior were collected at x2500. For measurement of total ECM, images were stitched together in ImageJ using the “pairwise stitching” plugin. The Trainable Weka Segmentation plugin was utilized to create a selection of the area occupied by ECM. For this, a specific classifier was created by drawing lines over the ECM, and separately over non-ECM structures (including empty spaces) to create the selected area and, ultimately, to mask the selection. The entire area of the TM was masked in ImageJ with the polygonal selection tool, and pixel area of TM was calculated, equating to the area occupied by ECM. In total, three animals from each genotype were evaluated, with two planes of stitched sections along the entire length of SC analyzed per mouse. For measurement of the length of basement membrane material (BMM) and size and density of giant vacuoles, images of the entire length of SC were collected at 12000x and stitched with plugging “pairwise stitching” in ImageJ as described above. Area of vacuoles was measured in ImageJ with polygonal tool selection, and length of BMM was measured with “segmented line” selection.
**Immunocytochemistry:**

Animals were euthanized by exposure to CO$_2$. Eyes were enucleated, and immediately transferred into 4% PFA in PBS and fixed overnight. Eyes were rinsed, dehydrated in increasing concentrations of ethanol, and embedded into paraffin. Five micron thick sections were cut. Sections were deparaffinized in two incubations of xylenes for 2 minutes each and then rinsed twice in 100% ethanol, 95% ethanol, and water, 2 minutes each. Antigen retrieval was performed in Sodium Citrate Buffer for 10 minutes at 95 degrees Celsius. Sections were incubated in Superblock for one hour and stained with primary antibody (see Table 1 list of antibodies) in Superblock overnight. Sections were rinsed trice in PBS, 10 min each time, and stained for two hours with appropriate fluorescently conjugated secondary antibodies. Finally, sections were rinsed, mounted into Prolong Diamond Antifade with DAPI (ThermoFisher #P36971) or without DAPI where applicable (ThermoFisher #P36970), and coverslipped. Images were acquired with a Nikon A2 laser confocal microscope (Nikon, Tokyo, Japan) using NIS elements software. Acquired Z-stacks were analyzed with ImageJ for a single plane selection.

**In Situ Hybridization:**

To detect Tlr4 mRNA mouse mRNA probes (#316801) were purchased from ACD company. Incubation and detection of probes was done according to manufacture instructions. Briefly, frozen sections (in OCT) on slides were baked at 60 degrees Celsius for 30 minutes, pretreated with hydrogen peroxide. Antigen retrieval was performed in Antigen Retrieval buffer for 5 minutes at 95 degrees Celsius. Slides were laid flat during the antigen retrieval step to diminish the chance of the section detaching. Hydrophobic borders were created around sections with ImmEdge pen (#H-4000, Vector Laboratories), and proteinase K applied for 30 minutes at 40 degrees Celsius, all performed in a humidified chamber. Sections were rinsed and the mRNA
probe was added for 2 hours, followed by a series of rinses and addition of amplification reagents each for 30 minutes. Signal was amplified with TSA Cy3 reagent (Akoya #SAT704A001EA). After in situ hybridization was accomplished, sections were additionally stained with antibodies against various targets (as described above) using fluorophore conjugated secondary antibody selected to avoid interference with RNA detection signal.

**Image Analysis:**

For image analysis of the percent of area occupied by specific cellular markers detected in confocal images of the ONH (IBA-1 for microglia, NF-200 for GC axons, GFAP for astrocytes), the total area of the ONH was calculated in ImageJ using the polygonal selection tool. Individual channels were separated, and a threshold mask (same threshold values in all conditions) was applied for individual channels, and threshold area of each channel was calculated. Percent of occupancy by individual threshold area of each channel inside of outlined ONH area was calculated in ImageJ. Similar analysis was performed for total FN and Iba1 labeling in the TM.

For quantification of numbers of mRNA particles in the TM and ONH, automatic counting was performed using ImageJ. Binary images of mRNA puncta were created by using a threshold (same values for all images) and creating a selection of it (Edit/Create Selection command) followed by Watershed processing function (Process/Binary/Watershed) to prevent counting cluster of puncta as a single value. Particles with a size less than two pixels were assigned as noise rather than signal and were not included in counting. Finally, puncta were counted and calculated per 100 square microns of masked area of TM.

**Western Blotting:**
Primary mouse astrocytes (passage 11) were isolated from mouse ONH as we previously described [32], and were grown to confluency in 6-well plates. Cells were rinsed with DPBS, and RIPA buffer (200µl/well) supplemented with protease/phosphatase cocktail inhibitors (MilliporeSigma #11836170001; #4906845001) was added for 10 min on ice with gentle rocking. The cell extract was collected and centrifuged at 14000xG for 10 minutes and protein concentration measured by BCA assay. Samples were loaded onto a polyacrylamide gel (25µg/well) and resolved with constant voltage at 200V for 45 min. Resolved samples from the gel were transferred to PVDF and blocked in the Intercept protein-free blocking buffer (LI-COR, #927-65001) for 1 hour at room temperature. Primary antibody (see Table 1) was added in the incubation buffer (same blocking buffer with addition of 0.2% Tween) and incubated overnight at 4 degrees Celsius. Secondary antibody was applied for one hour in incubation buffer at room temperature. Fluorescent signal was detected using the Odyssey Licor System.

Intraocular pressure measurements: IOP was measured with a rebound tonometer as we previously described [13, 24]. Mice were acclimated to the procedure room, and IOP was measured using a non-invasive method in isoflurane anesthetized mice with the TonoLab tonometer (Colonial Medical Supply, Franconia, NH). All measurements were made during the same 2-hour period of the lights-on phase. All IOP’s are represented as means (+/- SEM) and statistical significance determined by two-tailed paired Student’s t-test, n= 16-22 eyes/strain.

Quantification of retina ganglion cell loss: RGC loss was quantified in RPBMS labeled retina flat mounts and quantified by counting RBMPS positive cells in 4 central and 4 peripheral regions of the retina as previously described [33, 34]. Dissected retinas were pre-treated in 0.3% TritonX-100 in PBS for 30 min (x4) and then blocked in 0.3 % Triton X-100 in PBS containing 10% goat serum for 2 h. RGCs were labeled using anti-RBPMS antibody overnight at 4 °C. Following washes in PBS, the retinas were incubated with Donkey anti-Guinea Pig Cy3 conjugated antibody
(diluted in PBST) overnight at 4 °C and mounted with Vectashield Mounting Medium containing DAPI (Vector Laboratories #H-1200-10) and coverslipped. Images were collected using a epifluorescent Zeiss Axiovert microscope. Z-stacks (within a thickness of 50 microns, 5 microns per optical Z-slice) were collected of the entire mouse flat retinas with the central Z-focus on RGC layer to include all RGCs throughout the tiles of the entire retina. Tiles were automatically stitched in Zen Blue software. Images were opened in ImageJ, composites of Z-stacks were created, and total eight quadrants (0.25x0.25mm) were selected at the distance 0.7mm (central region) and 1.4mm (peripheral region) away from the ON. Cells were manually counted in ImageJ in a masked manner using the multi-point tool. For each individual retina, the RGC count was obtained by averaging the eight fields for each retina, and calculating average RGC number per square millimeter. Significance was determined by two-tailed paired Student’s t-test, n=10-14 eyes/strain.

Quantification of optic nerve damage: ON damage was assessed in sections of resin embedded ON’s by paraphenylenediamine (PPD) staining and ranked for damage using an ON damage score scale by two individuals in a masked manner as we previously described [35, 36]. Retro-orbital optic nerves were fixed, processed, and embedded in plastic. Optic nerve cross-sections were stained with PPD which stains the myelin sheaths and more darkly stains the axoplasm of sick or dying axons. We and others have previously quantified optic nerve damage successfully using semi-quantitative optic nerve grading schemes [36-39]. Here, we used a five-point optic nerve grading scheme [35]. Two investigators performed masked evaluations to grade each optic nerve, and optic nerve damage scores for each sample were averaged. Statistical significance was determined by Fisher's exact test, n=18-23 ONs/strain.
Results:

Previously, we reported that B6.EDA<sup>+/+</sup> mice have elevated IOP and increased total FN and FN containing the EDA isoform compared to C57BL/6J controls [24]. In addition, we showed normal open angle development in B6.EDA<sup>+/+</sup> mice by gross clinical and histological exams at 15, 30, and 60 days post-natal. Here, we recapitulate this data at 7 months of age in B6.EDA<sup>+/+</sup> and C57BL/6J mice with immunostaining of total FN (Figure 1A, 1B) and in situ hybridization of the EDA isoform of FN (Figure 1C, 1D). Both FN and the EDA isoform were significantly increased in the TM of B6.EDA<sup>+/+</sup> mice compared to controls (Figure 1E, 1F).

To further analyze the changes to the TM and ECM at the ultrastructural level, transmission electron microscopy studies were employed. The TM of B6.EDA<sup>+/+</sup> mice have fewer empty spaces between the trabecular beams, increases deposition of ECM throughout the TM, and inner side of TM had increased accumulation of ECM (Figure 2B, 2E) compared to the C57BL/6J control mice (Figure 2A, 2E). The ultrastructure of the TM in FN-EDA null mice (B6.EDA<sup>−/−</sup>) was comparable to that of the normal C57BL/6J mice with similar pattern of open spaces and little ECM deposition (Figure 2C, 2G). B6.EDA<sup>+/+</sup> mice have a significantly increased amount of ECM in the TM compared to C57BL/6J mice and B6.EDA<sup>−/−</sup> as quantified by ImageJ analysis, significance determined by one-way ANOVA (Figure 2D).

It has been suggested that the majority of the outflow resistance in the normal eye occurs at the inner wall endothelium of Schlemm’s canal (SC), its discontinuous basement membrane, and the juxtacanalicular connective tissue (JCT). The amount and density of basement membrane materials (BMM) underlying the inner wall of SC has been shown to be associated with elevated IOP and increased outflow resistance [1, 40, 41]. Here we analyzed the amount of BMM in B6.EDA<sup>+/+</sup> mice and C57BL/6J controls (Figure 3). Qualitatively we observed a thicker amount of amorphous material under the endothelial cells along the inner wall of SC in B6.EDA<sup>+/+</sup> mice (Figure 3E) in comparison to C57BL/6J control mice (Figure 3D).
We quantified the amount of BMM below the inner wall of SC following the approach described by Overby et al [40] (Figure 3A, 3B). This method measures the fraction of inner wall length exhibiting continuous basement membrane material, identified as a thin line of basal lamina-like structure underlying the inner wall endothelium of SC [40]. The length of the basement membrane material was measured in stitched contiguous sagittal sections, imaged at 12000X, spanning the entire anterior-to-posterior length of SC. Interestingly, we did not find a significant difference in BMM material (Figure 3C). The significant amount of amorphous-like ECM material throughout the TM and JCT region in B6.EDA +/+ mice made it very difficult to quantify the BMM utilizing the method described by Overby et al [40], and it is very likely we are underestimating the amount of BMM. Indeed, over 25% of the length of SC was unquantifiable for BMM due to the amorphous ECM impeding the analysis region (Figure 3F).

Giant vacuoles are involved in the transport of aqueous humor across the inner wall of SC. Here, we analyzed the size and number of giant vacuoles across the entire anterior to posterior length of SC, measured at 12000x (Figure 4A, 4B). B6.EDA +/+ mice had significantly more smaller giant vacuoles compared to C57BL/6J controls (Figure 4C), but similar overall numbers of giant vacuoles between the mouse strains (Figure 4D).

Previously, we identified that EDA-induced ocular hypertension was dependent on TLR4 [24]. Mice harboring both the constitutively active EDA isoform and knock out alleles of TLR4 (B6.EDA +/+TLR4 -/- mice) exhibited normal IOP and were resistant to TGFβ2-induced ocular hypertension. These data suggest that EDA is acting as a DAMP for TLR4 activation. Here, we evaluated the levels of Tlr4 mRNA expression in the TM of C57BL/6J control and B6.EDA +/+ mice (Figure 5). Tlr4 mRNA (red puncta) is detected in the TM of both C57BL/6J control (Figure 5A,C) and B6.EDA +/+ mice (Figure 5B,D), and levels of Tlr4 mRNA are significantly increased in the TM of B6.EDA +/+ mice (Figure 5E). In addition, there are increased numbers of Iba1 positive macrophages in the TM of B6.EDA +/+ mice compared to control eyes (Figure 5F), which may be relevant to a fibro-inflammatory response in the TM.
As previously reported, B6.EDA^{+/+} mice have significantly higher IOP pressure than C57BL/6J control mice [24]. Here, we recapitulate this data and demonstrate that the IOP remains significantly elevated in B6.EDA^{+/+} mice at 12 months of age (Figure 6A). Since increased IOP is associated with the risk of damage to the RGC’s and axons, we analyzed RGC cell numbers in RBPMS labeled retina flat mounts and found a 9.8% decrease in RGC numbers in the B6.EDA^{+/+} retinas compared to C57BL/6J controls at 12 months of age (Figure 6B). In addition, utilizing a well-established Optic Nerve Damage Scoring rubric [35], we quantified axonal integrity in the ON. ONs from B6.EDA^{+/+} and C57BL/6J control mice at 12 months of age were scored in a masked manner by two independent individuals. There is significantly more damage in the ONs of B6.EDA^{+/+} mice, with many ONs scoring a “2” indicative of mild ON damage and approximately 10% of darkly stained axons and initial stages of gliosis [35] (Figure 6C, D).

The ONH region also contains microglia and astrocytes, both of which have been shown to be important in the initial stages of glaucomatous damage. Here, we analyzed the expression of astrocyte marker GFAP, microglia marker Iba1, and axon marker NF200 in the ONH of C57BL6/J control and B6.EDA^{+/+} mice at 8-9 months of age, (Figure 7). There was a significant increase in the area occupied by Iba-1 positive microglia in the ONH of B6.EDA^{+/+} mice compared to controls (Figure 7A, 7B, 7I). Increased Iba-1 expression is an indicator of increased microglia activation and density and is a known marker of early glaucomatous changes, proceeding RGC loss and ON damage [42-46]. GFAP was expressed throughout the ONH in C57BL6/J control and B6.EDA^{+/+} mice with no significant difference in the area occupied by GFAP (Figure 7E, 7F, 7J). There was also no significant difference in NF200 labeled RGC axons as quantified by immunolabeling in cryopreserved cross-sections (Figure 7C, 7D, 7K).

Given the importance of FN-EDA in activation of TLR4, we determined the expression of Tlr4 in the ONH cells of C57BL/6J and B6.EDA^{+/+} mice by RNAscope in situ hybridization. Tlr4
mRNA is expressed in mouse RGC axons, microglia, and astrocytes (Figure 8). The specificity of the *Tlr4* probe was validated using TLR4−/− mice (Supplemental Figure 1). No significant difference in *Tlr4* mRNA expression was detected in ONH astrocytes or RGC axons between C57BL/6J and B6.EDA+/+ mice. However, the percent of Iba1 positive cells expressing *Tlr4* mRNA was significantly increased in the ONH of B6.EDA+/+ mice compared to controls (Figure 8D). We further evaluated the expression of TLR4 protein in primary astrocyte cultures derived from the mouse ONH tissue (Figure 9). Astrocytes were characterized by detection of astrocyte-specific marker GFAP (Figure 9A,9B). Similar to the in-situ hybridization data (Figure 8B) TLR4 protein was also detected in the isolated primary ONH astrocytes in culture (Figure 9C).

**Discussion:**

Mice have long been used as a model system for ocular hypertension and glaucoma [47] due to the genetic similarity to humans as well as comparable ocular anatomy and physiology, including that of the conventional outflow pathway [48-54]. Importantly, mice can easily be genetically manipulated, specific genes can be targeted, and mouse genetics can be utilized to uncover modifier genes leading to various disease relevant phenotypes. Previously, we utilized several transgenic mouse strains to determine that both TLR4 and the EDA isoform of FN are necessary for TGFβ2-induced ocular hypertension [24]. In addition, we showed that constitutively active EDA mice developed ocular hypertension by 14 weeks of age [24]. These data suggest that B6.EDA+/+ mice harbor important phenotypes of ocular hypertension and glaucomatous TM damage. Here, we further investigate the role of FN-EDA in generating elevated IOP by examining the ECM makeup and ultrastructure of the TM by light and electron microscopy. In addition, we demonstrate subsequent RGC loss and ON damage B6.EDA+/+ following sustained IOP elevation.
The ultrastructure changes in the TM of B6.EDA<sup>+/+</sup> mice resemble the changes previously reported in other models of ocular hypertension and in human patients with POAG, demonstrating an increase in ECM deposition in the TM [2-4, 40, 55]. It is believed that the inner wall of SC and the JCT are the primary location for aqueous humor outflow resistance [2, 3]. The presence of ECM in the TM and JCT region is necessary to maintain the outflow as it creates space between cells and trabecular lamina, and the ECM is also bound to proteoglycans which have been shown to be necessary for efficient outflow [5]. There are several types of ECM in the TM which are constantly secreted, maintained, and recycled by TM cells. However, with aging and/or disease the normal balance of ECM production and degradation appears to be disrupted, leading to increased resistance to outflow and elevated IOP. In addition, it is known that in POAG the connecting fibrils between the JCT TM and SC inner wall endothelium are thickened forming sheath-derived plaques; and the basement membrane material underlying SC endothelium is thicker and more continuous [9]. Abnormal accumulation of ECM material in the TM and JCT region has been shown in several histological analyzes of POAG eyes [4, 10, 23, 56-58]. Amorphous ECM material in the JCT region is made up of primarily collagen type IV, laminin, and fibronectin [59]. The ECM material and sheath-derived plaques in the JCT region and on the inner side of SC endothelium is increased in glaucomatous eyes [4, 9, 60]. These data are recapitulated here in our B6.EDA<sup>+/+</sup> mouse model where we have identified an increase in FN protein expression by immunohistochemistry and total ECM accumulation by electron microscopy.

Aqueous humor is transported across the inner wall endothelium of SC through tight junctions of SC cells, as well as through the formation of giant vacuoles and associated pores in SC endothelial cells [61-63]. The cavity of giant vacuoles are entirely extracellular and giant vacuoles are described as outpouchings of the SC endothelial cells themselves. Giant vacuoles bulge into the lumen of SC with the aqueous humor filled cavity remaining between the cell and
the underlying basement membrane [64, 65]. Early studies by Tripathi et al showed a quantitative and qualitative depletion of giant vacuoles in glaucoma [60]. In addition, previous histological studies have demonstrated a decrease in the number of pores in eyes with POAG [66, 67]. However, more recently a study identified similar giant vacuole size and density in perfused POAG eyes despite a lower flow rate in the POAG eyes due to higher flow resistance [2]. Consistent with these results, we show similar giant vacuole numbers between control and B6.EDA^{+/+} mice, but B6.EDA^{+/+} do have significantly more smaller giant vacuoles. However, it is not known if there is a decrease in the number of giant vacuoles with pores in POAG or in the B6.EDA^{+/+} mice.

In addition to changes in the ECM of the TM, we also observed a significant increase in Iba-1 positive cells in B6.EDA^{+/+} mice compared to controls. Iba1 is specifically expressed in macrophages/microglia and is upregulated during the activation of these cells. Macrophages are known to be present in the TM [68, 69] and there is some evidence that macrophage inflammatory proteins are differentially expressed in the TM from POAG patients [70]. Previous studies also suggest that during glaucoma macrophages produce cytokines such as IL6, IL1β and TNFα that could lead to an acute inflammatory response [70, 71]. Although the existing literature suggests macrophages are present in the TM and may produce disease-relevant signaling molecules, a role for macrophages in IOP regulation and ocular hypertension has not been identified.

We have previously identified that EDA-induced ocular hypertension and EDA-induced ECM production is dependent on TLR4 [13, 24]. In addition, TLR4 is known to be expressed in the TM [13, 72]. Here, we demonstrate by RNAscope in situ hybridization that Tlr4 is expressed in the mouse TM and increased in the TM of B6.EDA^{+/+} mice compared to controls. These data highlight the importance of EDA activated TLR4 in the regulation of ECM and ocular hypertension. In addition, we also demonstrate the expression of Tlr4 in mouse ONH astrocytes,
microglia and RGC axons by RNAscope in situ hybridization. There have been conflicting reports on the expression of Tlr4 in rodent astrocytes; however, these studies involved astrocytes isolated from brain which could indicate tissue specific expression [73-76]. Consistent with our findings, Gorina et al reported expression of Tlr4 in mouse astrocytes [77]. Further analysis of the ONH cells and tissue will determine the role of TLR4 and FN-EDA in the development of glaucomatous damage.

In POAG, elevated IOP is followed by progressive damage to the ONH and loss of RGCs. Previously it has been reported that microglial activation is also associated with early stages of experimental glaucoma [44, 78-81], and the extent of microglial activation is closely related to axonal degeneration [42, 45]. Increased expression of Iba1 has previously been used as a measure of microglial activation in the ONH and other parts of the CNS [44, 82]. Here we show that Iba1 expression is increased in the ONH of B6.EDA+/+ mice compared to controls at 8-9 months of age. Subsequently, at 12 months of age we show mild ON damage and loss of RGCs. We utilized a well-established ON grading scheme [35] of p-phenylenediamine (PPD) stained cross-sections of ONs. Based on the extent of staining, masked observers assign a score of 1-5 to each section, with a score of 1 indicating very few dark staining axons, no identifiable gliosis or axonal swelling. A score of 5 indicates less than 10% of axons alive and gliosis and darkly stained axons making up 95% of the ON. Here, many of the ONs in B6.EDA+/+ mice scored 2 on the grading scale, indicative of 5-10% darkly stained axons and the initial stage of gliosis. Although this type of grading scheme is semiquantitative in nature, it has previously been found to correlate well with RGC density and axon density in the ON [37, 38]. Indeed, we found a correlative loss of 9.7% of RGC axons at 12 months of age in B6.EDA+/+ mice. In summary, these data show the development of slowly progressive glaucomatous damage in B6.EDA+/+ mice.
Conclusions

Our results show that B6.EDA+/+ mice have ultrastructural changes to the TM consistent with POAG. We also demonstrate the differential expression of key fibrotic pathway components, FN, FN-EDA, and TLR4 in the TM of B6.EDA+/+ mice. In addition, we described early microglial activation and subsequent glaucomatous damage to the retina and ON. In summary, B6.EDA+/+ mice harbor many phenotypes of glaucoma and provide an excellent resource to study the molecular pathology of the disease.

List of abbreviations: Fibronectin: FN, Fibronectin extra domain A: FN-EDA, Toll like receptor 4: Tlr4, trabecular meshwork: TM, Schlemm’s canal: SC, juxtacanalicular tissue: JCT, primary open angle glaucoma: POAG, intraocular pressure: IOP, aqueous humor: AH, giant vacuoles: GV, basement membrane material: BMM

Declarations

Ethics approval and consent to participate: All studies were approved (Protocol #M006172) by the local institutional animal care use committee (IACUC), and all animals were treated in accordance with published NIH standards and with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research.

Consent for publication: Not applicable
Availability of data and materials: All data generated or analyzed during this study are included in this published article [and its supplementary information files] and are available from the corresponding author on reasonable request.

Competing interests: The authors declare that they have no competing interests.

Funding: This work was supported by National Institute of Health R01EY02652 (CMM). This work was also supported in part by an Unrestricted Grant from Research to Prevent Blindness to the UW-Madison Department of Ophthalmology and Visual Sciences, and the Core Grant for Vision Research from the NIH to the University of Wisconsin-Madison (P30 EY016665). The generation and maintenance of the mouse strains was supported by National Institutes of Health grant (R35HL139926, R01NS109910 & U01NS113388) and Established Investigator Award 18EIA33900009 from American Heart Association (AKC).

Authors’ contributions: CMM developed all ideas and experimental designs, performed IOP measurements, analyzed data, and wrote the manuscript. TAM performed all histological and molecular experiments, analyzed data, and wrote the manuscript. JJM analyzed data. YL isolated and cultured primary mouse astrocytes. AKC generated B6.EDA^{+/+}, B6.EDA^{-/-}, and B6.TLR4^{-/-} mouse strains. All authors read and approved the final manuscript.

**Figure Legends**

**Figure 1.** Total Fibronectin and Fibronectin-EDA expression is increased in the TM of *B6.EDA*<sup>+/+</sup> mice. (A, B) Total FN expression is increased in the TM of B6.EDA<sup>+/+</sup> mice compared to C57BL/6J controls as shown by immunohistochemical analysis (green labeling). (C, D) The EDA isoform of FN is increased in the TM of B6.EDA<sup>+/+</sup> mice compared to C57BL/6J controls as
shown by RNAscope in situ hybridization (red puncta). Both total FN (E) and FN-EDA (F) were significantly increased when quantified by ImageJ analysis of mean fluorescent intensity and puncta/mm$^2$, respectively. Significance determined by Student’s t-test. *=p<0.05, n=3 mice/strain, scale bar = 50µm.

**Figure 2. ECM accumulation is increased in the TM of B6.EDA$^{+/+}$ mice.** (A, B, C) Montage of low magnification images (2650X) shows entire TM and inner part of SC in eyes of C57BL/6J control (A), B6.EDA$^{+/+}$ (B), and EDA$^{-/-}$ mice (C). Regions outlined in the red box in upper panels are enlarged in lower panels (C57BL/6J (E), B6.EDA$^{+/+}$ (F), and B6.EDA$^{-/-}$ (G)). Throughout the entire length of the TM fewer empty spaces (green asterisks) exist in the TM of B6.EDA$^{+/+}$ eyes compared to C57BL/6J controls. A network of ECM surrounds the inner most part of the TM in B6.EDA$^{+/+}$ eyes (red arrows), while it is almost absent in C57BL/6J control eyes. D. Area occupied by ECM in the TM was significantly increased in B6.EDA$^{+/+}$ eyes compared to C57BL/6J and B6.EDA$^{-/-}$ eyes. Significance determined by one-way ANOVA, ***=p<0.001, **=p<0.01, n= 3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 5µm.

**Figure 3. B6.EDA$^{+/+}$ mice have increased amorphous ECM and changes to basement membrane material along the inner wall of SC.** (A, B) Fragment of the stitched image of the entire length of SC (A) and a representative example of how the percent length of BMM along the inner wall of SC was measured (B). The inner wall of SC is marked with a green line and BMM marked with red a line. (C) Percent of BMM covering the length of the SC in C57BL/6J and B6.EDA$^{+/+}$ mice. (D, E) Large portions of the inner SC endothelium is covered by amorphous ECM material (red arrows) in B6.EDA$^{+/+}$ mice, which may conceal the BMM (yellow arrows), and makes it more difficult to detect of BMM in these regions. (F) Length of SC that is unquantifiable for BMM due to amorphous material under the endothelium in C57BL/6J and
B6.EDA^{+/+} mice. n= 3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 1µm.

**Figure 4.** B6.EDA^{+/+} mice have smaller giant vacuoles. (A, B) Fragment of the stitched image of the entire length of SC of C57BL/6J (A) and B6.EDA^{+/+} (B) mice. C. Quantified percent of giant vacuoles with various sizes from C57BL/6J and B6.EDA^{+/+} mice. B6.EDA^{+/+} mice had significantly more smaller giant vacuoles. (D) Total number of giant vacuoles per 100µm². Significance determined by Chi-square, p<0.05, n=3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 2µm.

**Figure 5.** B6.EDA^{+/+} mice have increased expression of Tlr4 and Iba1 in the TM. (A, B) Merged fluorescent and brightfield images show increased expression of Tlr4 mRNA by in situ hybridization and Iba1 by immunofluorescent labeling in the TM of B6.EDA^{+/+} mice (B) compared to controls (A). Unmerged images shown for C57BL/6J (C) and B6.EDA^{+/+} (D). Puncta of Tlr4 mRNA is red, Iba-1 positive macrophages are green, blue is DAPI nuclear stain. Scale = 100 µm. (E) Total Tlr4 mRNA puncta in TM of C57BL/6J and B6.EDA^{+/+} mice quantified by ImageJ analysis. (D) Quantified coverage of TM area by Iba-1 positive expression in C57BL/6J and B6.EDA^{+/+} mice. Significance determined by Student’s t-test, * = p<0.05, n = 3 mice/strain.

**Figure 6.** B6.EDA^{+/+} mice have elevated IOP, RGC loss, and ON damage. (A) IOP is significantly elevated in B6.EDA^{+/+} mice (n=16) compared to C57BL6/J (n=22) at 12 months of age, mean +/- SEM. Significance determined by Student’s t-test. (B) B6.EDA^{+/+} mice (n=10) have 9.7% loss of RGCs at 12 months of age compared to C57BL/6J (n=15) as quantified by RBPMS stained retinal flat mounts. Significance determined by Student’s t-test (C) Percent of axons with no damage (1) or with mild damage (2) in transverse sections of optic nerves in
B6.EDA^+/+ (n=23) and C57BL/6J (n=18) mice. B6.EDA^+/+ have significantly more ON damage compared to C57BL/6J, Significance determined by Fisher's exact test. (D) Images of representative transverse sections of optic nerves of B6.EDA^+/+ and C57BL/6J mice. * = p<0.05, ****=p<0.0001.

**Figure 7. B6.EDA^+/+ mice have increased Iba1 expression in the ONH.** (A-H) Immunohistochemistry staining for microglia (purple) by Iba1 antibody labeling (A, B), RGC axons (green) by NF200 antibody labeling (C,D), and astrocytes (blue) by GFAP antibody labeling (E,F) in the ONH of C57BL/6J and B6.EDA^+/+ mice at 8-9 months of age. (A, B, I) B6.EDA^+/+ mice have increased area covered by Iba-1 positive expression in the ONH compared to C57BL/6J controls. (C, D, J) No significant difference detected in coverage by NF200 labeled ganglion cell axons. (E, F, K) No significant difference detected in coverage by GFAP labeled astrocytes. Significance determined by Student’s t-test. Scale bar = 50 μm. n=3 mice/strain.

**Figure 8. Tlr4 is expressed in RGC axons, astrocytes, and microglia in the mouse ONH.**

Tlr4 mRNA shown as white puncta in all images by RNAScope in situ hybridization in combination with immunofluorescent labeling of axons, astrocytes, and microglia. (A) Tlr4 mRNA is detected in RGC axons (green), (B) in ONH astrocytes (blue) and (C) in ONH microglia (magenta). A' and A'' are magnified fragments of A; B' and B'' are magnified fragments of B; C' and C'' are magnified fragments of C. Yellow arrows point to localization of TLR4 mRNA in cells positive for specific markers. (D) Bar graph showing percent of Iba1 positive cells with detected TLR4 mRNA in C57BL/6J control and B6.EDA^+/+ mice. Significance determined by Student’s t-test. Scale=50μm. n= 3 mice/strain.
**Figure 9. TLR4 is expressed in primary mouse ONH astrocytes.** (A) Astrocytes isolated from the mouse ONH express astrocyte-specific marker GFAP. Scale bar = 50 μm. (B) Cell lysates were isolated from the primary astrocyte cultures and GFAP (50kD, red) and GAPDH (37kD, green) expression detected by western blot. (C) Cell lysates isolated from primary astrocyte cultures were isolated and TLR4 (73 kDa, green) and GAPDH (37kD, red) expression detected by western blot.

**Supplemental Figure 1. Mouse Tlr4 mRNA probe is specific.** (A, B) In situ hybridization of Tlr4 in C57BL/6J controls confirms expression of Tlr4 in the mouse ONH, while no specific labeling was detected in Tlr4 knock out (TLR4−/−) mice.
Figure 1

Total Fibronectin and Fibronectin-EDA expression is increased in the TM of B6.EDA+/+ mice. (A, B) Total FN expression is increased in the TM of B6.EDA+/+ mice compared to C57BL/6J controls as shown by immunohistochemical analysis (green labeling). (C, D) The EDA isoform of FN is increased in the TM of B6.EDA+/+ mice compared to C57BL/6J controls as shown by RNAscope in situ hybridization (red puncta). Both total FN (E) and FN-EDA (F) were significantly increased when quantified by ImageJ.
analysis of mean fluorescent intensity and puncta/mm², respectively. Significance determined by Student’s t-test. *p<0.05, n=3 mice/strain, scale bar = 50µm.

**Figure 2**

ECM accumulation is increased in the TM of B6.EDA+/+ mice. (A, B, C) Montage of low magnification images (2650X) shows entire TM and inner part of SC in eyes of C57BL/6J control (A), B6.EDA+/+ (B), and EDA/- mice (C). Regions outlined in the red box in upper panels are enlarged in lower panels.
Throughout the entire length of the TM fewer empty spaces (green asterisks) exist in the TM of B6.EDA+/+ eyes compared to C57BL/6J controls. A network of ECM surrounds the inner most part of the TM in B6.EDA+/+ eyes (red arrows), while it is almost absent in C57BL/6J control eyes. D. Area occupied by ECM in the TM was significantly increased in B6.EDA+/+ eyes compared to C57Bl/6J and B6.EDA-/ - eyes. Significance determined by one-way ANOVA, ***=p<0.001, **=p<0.01, n= 3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 5µm.

**Figure 3**

B6.EDA+/+ mice have increased amorphous ECM and changes to basement membrane material along the inner wall of SC. (A, B) Fragment of the stitched image of the entire length of SC (A) and a representative example of how the percent length of BMM along the inner wall of SC was measured (B). The inner wall of SC is marked with a green line and BMM marked with red a line. (C) Percent of BMM covering the length of the SC in C57BL/6J and B6.EDA+/+ mice. (D, E) Large portions of the inner SC endothelium is covered by amorphous ECM material (red arrows) in B6.EDA+/+ mice, which may conceal the BMM (yellow arrows), and makes it more difficult to detect of BMM in these regions. (F) Length of SC that is unquantifiable for BMM due to amorphous material under the endothelium in C57BL/6J and B6.EDA+/+ mice. n= 3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 1µm.
Figure 4

B6.EDA+/+ mice have smaller giant vacuoles. (A, B) Fragment of the stitched image of the entire length of SC of C57BL/6J (A) and B6.EDA+/+ (B) mice. C. Quantified percent of giant vacuoles with various sizes from C57BL/6J and B6.EDA+/+ mice. B6.EDA+/+ mice had significantly more smaller giant vacuoles. (D) Total number of giant vacuoles per 100µm². Significance determined by Chi-square, p<0.05, n=3 mice/strain, two planes of stitched sections along the entire length of SC analyzed per mouse, scale bar = 2µm.
Figure 5

B6.EDA+/+ mice have increased expression of Tlr4 and Iba1 in the TM. (A, B) Merged fluorescent and brightfield images show increased expression of Tlr4 mRNA by in situ hybridization and Iba1 by immunofluorescent labeling in the TM of B6.EDA+/+ mice (B) compared to controls (A). Unmerged images shown for C57BL/6J (C) and B6.EDA+/+ (D). Puncta of Tlr4 mRNA is red, Iba-1 positive macrophages are green, blue is DAPI nuclear stain. Scale = 100 µm. (E) Total Tlr4 mRNA puncta in TM of C57BL/6J and B6.EDA+/+ mice quantified by ImageJ analysis. (D) Quantified coverage of TM area by Iba-1 positive expression in C57BL/6J and B6.EDA+/+ mice. Significance determined by Student's t-test, * = p<0.05, n = 3 mice/strain.
B6.EDA+/+ mice have elevated IOP, RGC loss, and ON damage. (A) IOP is significantly elevated in B6.EDA+/+ mice (n=16) compared to C57BL6/J (n=22) at 12 months of age, mean +/- SEM. Significance determined by Student’s t-test. (B) B6.EDA+/+ mice (n=10) have 9.7% loss of RGCs at 12 months of age compared to C57BL/6J (n=15) as quantified by RBPMS stained retinal flat mounts. Significance determined by Student’s t-test (C) Percent of axons with no damage (1) or with mild damage (2) in
transverse sections of optic nerves in B6.EDA+/+ (n=23) and C57BL/6J (n=18) mice. B6.EDA+/+ have significantly more ON damage compared to C57BL/6J, Significance determined by Fisher's exact test. (D) Images of representative transverse sections of optic nerves of B6.EDA+/+ and C57BL/6J mice. * = p<0.05, ****=p<0.0001.

Figure 7

B6.EDA+/+ mice have increased lba1 expression in the ONH. (A-H) immunohistochemistry staining for microglia (purple) by lba1 antibody labeling (A, B), RGC axons (green) by NF200 antibody labeling (C,D), and astrocytes (blue) by GFAP antibody labeling (E,F) in the ONH of C57BL/6J and B6.EDA+/+ mice at 8-9 months of age. (A, B, I) B6.EDA+/+ mice have increased area covered by lba-1 positive expression in the ONH compared to C57BL/6J controls. (C, D, J) No significant difference detected in coverage by NF200
Tlr4 is expressed in RGC axons, astrocytes, and microglia in the mouse ONH. Tlr4 mRNA shown as white puncta in all images by RNAScope in situ hybridization in combination with immunofluorescent labeling of axons, astrocytes, and microglia.
