Abstract We study potential operators associated with Laguerre function expansions of convolution and Hermite types, and with Dunkl-Laguerre expansions. We prove qualitatively sharp estimates of the corresponding potential kernels. Then we characterize those \(1 \leq p, q \leq \infty\), for which the potential operators are \(L^p \rightarrow L^q\) bounded. These results are sharp analogues of the classical Hardy-Littlewood-Sobolev fractional integration theorem in the Laguerre and Dunkl-Laguerre settings.

potentials $I^\sigma = (-\Delta)^{-\sigma}$, where $\Delta$ denotes the Euclidean Laplacian in $\mathbb{R}^d$, $d \geq 1$, is related to continuous expansions with respect to the system $\{\exp(2\pi i \langle \cdot, \xi \rangle) : \xi \in \mathbb{R}^d\}$. The $L^p - L^q$ boundedness of $I^\sigma$, $0 < \sigma < d/2$, is characterized by the celebrated Hardy-Littlewood-Sobolev theorem.

There is a wide variety of papers and results pertaining to potential operators in numerous orthogonal expansion settings, both continuous and discrete. For instance, Anker [1] studied potential operators in the framework of non-compact symmetric spaces and his analysis was based on sharp pointwise estimates of the corresponding kernels. In [3] Bongioanni and Torrea investigated potential operators related to the harmonic oscillator $\mathcal{H} = -\Delta + \|x\|^2$, which plays the role of a Laplacian in the context of multi-dimensional Hermite function expansions. Some complementary comments on that research are contained in [9, Section 2]. More recently, in [10] it was shown that the $L^p - L^q$ bounds obtained in [3] for the potential operator $I^\sigma = \mathcal{H}^{-\sigma}$ are in fact sharp in the sense of admissible $p$ and $q$. This was achieved as a consequence of qualitatively sharp estimates for the integral kernel of $I^\sigma$ established also in [10]. A thorough study of potential operators associated with classical one-dimensional Jacobi and Fourier-Bessel expansions was furnished by Nowak and Roncal [7]. The corresponding analysis is also based on sharp estimates of the potential kernels proved in that work. Similar questions in the settings of Hankel and Hankel-Dunkl transforms have just been studied by the authors in [11].

Potential operators related to multi-dimensional Laguerre operators in $\mathbb{R}^d_+$, and to the Dunkl harmonic oscillator in $\mathbb{R}^d$ with the underlying reflection group isomorphic to $\mathbb{Z}^d_2$, were investigated by the authors in [9]. Recall that the latter ‘Laplacian’ is a differential-difference operator, and its eigenfunctions express via certain Laguerre functions. Hence the associated expansions are sometimes referred to as Dunkl-Laguerre expansions. The aim of [9] was to prove $L^p - L^q$ bounds for the considered potential operators for a possibly wide range of $p$ and $q$. Another objective was to obtain in a similar spirit two-weight $L^p - L^q$ bounds, with power weights involved. All these results in [9] were derived as indirect and somewhat tricky consequences of analogous theory for $I^\sigma$, and under the restriction $\alpha \in [-1/2, \infty)^d$ on the multi-parameter of type.

The present paper is motivated by the natural question to what extent the results of [9] are optimal in the sense of admissible $p$ and $q$. Further motivation comes from a related problem, but certainly of independent interest, of describing the behavior of the relevant potential kernels via pointwise estimates. Finally, yet another motivation follows from a desire to get rid of the above mentioned restriction on $\alpha$. All these inspirations found a positive outcome. For technical reasons, we consider only $d = 1$ and thus work in dimension one, otherwise the analysis we present would become much more sophisticated. Then we investigate the settings from [9], that is, according to the terminology used in [14], the situations of Laguerre function expansions of convolution and Hermite types, and Dunkl-Laguerre expansions (see Section 2 for the definitions), with no artificial restrictions on $\alpha$ imposed. We prove qualitatively sharp estimates for the relevant potential kernels (Theorems 2.1 and 2.4). Then we characterize those $1 \leq p, q \leq \infty$, for which the potential operators are $L^p - L^q$ bounded (Theorems 2.2, 2.3 and 2.6). In particular, it follows that the unweighted $L^p - L^q$ bounds from [9] are in fact sharp, at least in the one-dimensional case. It is remarkable that our present results enable further research which is no doubt of interest, but beyond the scope of this work. Let us mention here the following issues:

- characterization of weak type and restricted weak type inequalities for the potential operators (see [7, Theorems 2.3, 2.4, 2.7, 2.8]),
• characterization of two-weight $L^p - L^q$ inequalities for the potential operators, with power weights involved (see [9, Theorems 1.2, 2.5, 3.3, 4.2, 6.2]; note that it is known that at least some of these results are not optimal),
• development of analogous theory for other variants of fractional integrals in the Laguerre and Dunkl-Laguerre settings, or more generally, for Laplace-Stieltjes type multipliers (see the comments closing [9, Section 2] and [9, Section 3]).

We note that the results of this paper concerning the analogues of the classical Riesz potentials contain implicitly parallel results for counterparts of the classical Bessel potentials $(\text{Id} - \Delta)^{-\sigma}$. This is because spectra of the ‘Laplacians’ considered are already separated from 0. By tracing the proofs of Theorems 2.1 and 2.4 it is straightforward to see that integral kernels of Bessel potentials in the Laguerre and Dunkl-Laguerre settings also satisfy the qualitatively sharp bounds stated there. Consequently, Theorems 2.2, 2.3 and 2.6 remain true if the Laguerre and Dunkl-Laguerre Riesz potentials are replaced by analogues of Bessel potentials in these contexts.

Finally, we remark that although the present framework is one-dimensional, it has, at least in the setting of Laguerre expansions of convolution type, a multi-dimensional background. More precisely, if $\alpha = n - 1, n \geq 1$, then the context of Laguerre function expansions of convolution type is related to a ‘radial’ analysis in $\mathbb{C}^n$ equipped with twisted convolution, see [13, 14] for details. Continuing this line of thought, we note that the system of Laguerre functions of Hermite type also has a multi-dimensional connection, since it consists of eigenfunctions of the Hankel transform.

The paper is organized as follows. In Section 2 we briefly introduce the settings to be investigated and state the main results (Theorems 2.1-2.4 and 2.6). The corresponding proofs are contained in the two succeeding sections. In Section 3 we show qualitatively sharp estimates for the relevant potential kernels. Section 4 is devoted to characterizing $L^p - L^q$ boundedness of the Laguerre and Dunkl-Laguerre potential operators.

Throughout the paper we use a standard notation, which is consistent with that used in [9, 10]. In particular, we write $X \lesssim Y$ to indicate that $X \leq CY$ with a positive constant $C$ independent of significant quantities. We shall write $X \simeq Y$ when simultaneously $X \lesssim Y$ and $Y \lesssim X$. Furthermore, $X \simeq Y \exp(-cZ)$ means that there exist positive constants $C, c_1, c_2$, independent of significant quantities, such that

$$C^{-1}Y \exp(-c_1Z) \leq X \leq CY \exp(-c_2Z).$$

In a number of places we will use natural and self-explanatory generalizations of the “$\sim\sim$” relation, for instance, in connection with certain integrals involving exponential factors. In such cases the exact meaning will be clear from the context. By convention, “$\sim\sim$” is understood as “$\simeq$” whenever no exponential factors are involved.

We treat positive kernels and integrals as expressions valued in the extended half-line $[0, \infty)$. Similar remark concerns expressions occurring in various estimates, with the natural limiting interpretations like, for instance, $(0^+)\beta = \infty$ when $\beta < 0$.

2 Preliminaries and Statement of Results

We will consider two interrelated settings corresponding to one-dimensional Laguerre function expansions of convolution type and of Hermite type. Also, we will study the one-dimensional context of Dunkl-Laguerre expansions associated with the Dunkl harmonic
oscillator and the underlying group of reflections isomorphic to $\mathbb{Z}_2$. The latter situation may be regarded as an extension of that of Laguerre function expansions of convolution type, see Section 2.3 below. All the three frameworks in question have deep roots in the existing literature. In particular, in the last decade they were widely investigated from the harmonic analysis perspective. For all the facts (tacitly) invoked in what follows we refer to [9] and references given there.

2.1 Laguerre Function Setting of Convolution Type

Let $\alpha > -1$. The Laguerre functions of convolution type are given by

$$\ell_n^\alpha(x) = c_n^\alpha L_n^\alpha(x^2) \exp\left(-x^2/2\right), \quad x > 0,$$

where $c_n^\alpha > 0$ are the normalizing constants, and $L_n^\alpha$, $n \geq 0$, are the classical Laguerre polynomials. The system $\{\ell_n^\alpha : n \geq 0\}$ is an orthonormal basis in $L^2(d\mu_\alpha)$, where $\mu_\alpha$ is the measure on the half-line $\mathbb{R}_+ = (0, \infty)$ defined by

$$d\mu_\alpha(x) = x^{2\alpha+1} dx.$$

The $\ell_n^\alpha$ are eigenfunctions of the Laguerre ‘Laplacian’

$$L_\alpha = -\frac{d^2}{dx^2} - \frac{2\alpha + 1}{x} \frac{d}{dx} + x^2,$$

we have $L_\alpha \ell_n^\alpha = (4n+2\alpha+2)\ell_n^\alpha$. We denote by the same symbol $L_\alpha$ the natural self-adjoint extension whose spectral resolution is given by the $\ell_n^\alpha$. The integral kernel $G_t^\alpha(x, y)$ of the Laguerre heat semigroup $\{\exp(-tL_\alpha)\}$ can be expressed explicitly in terms of the modified Bessel function $I_\alpha$.

More precisely,

$$G_t^\alpha(x, y) = \frac{1}{\sinh 2t} \exp\left(-\frac{1}{2} \coth(2t) \left(x^2 + y^2\right)\right) (xy)^{-\alpha} I_\alpha \left(\frac{xy}{\sinh 2t}\right), \quad x, y > 0.$$

(1)

Given $\sigma > 0$, we consider the potential operator

$$I^{\alpha,\sigma} f(x) = \int_0^\infty K^{\alpha,\sigma}(x, y) f(y) d\mu_\alpha(y), \quad x > 0,$$

where the potential kernel is defined as

$$K^{\alpha,\sigma}(x, y) = \frac{1}{\Gamma(\sigma)} \int_0^\infty G_t^\alpha(x, y) t^{\sigma-1} dt, \quad x, y > 0.$$

We will prove the following general and qualitatively sharp estimates of $K^{\alpha,\sigma}(x, y)$.

**Theorem 2.1** Let $\alpha > -1$ and let $\sigma > 0$. The following estimates hold uniformly in $x, y > 0$.

(i) If $x + y \leq 1$, then

$$K^{\alpha,\sigma}(x, y) \simeq \chi_{\sigma>\alpha+1} + \chi_{\sigma=\alpha+1} \log \frac{1}{x+y} + (x+y)^{-2\alpha-1} \begin{cases} |x-y|^{2\sigma-1}, & \sigma < 1/2, \\ 1 + \log \frac{x+y}{|x-y|}, & \sigma = 1/2, \\ (x+y)^{2\sigma-1}, & \sigma > 1/2. \end{cases}$$

(ii) If $x + y > 1$, then

$$K^{\alpha,\sigma}(x, y) \simeq (x+y)^{-2\alpha-1} \exp(-c|x-y|(x+y)) \begin{cases} |x-y|^{2\sigma-1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{1}{|x-y|(x+y)}, & \sigma = 1/2, \\ (x+y)^{1-2\sigma}, & \sigma > 1/2. \end{cases}$$
Thus, among other things, we see that the kernel behaves in an essentially different way, depending on whether \((x, y)\) is close to the origin of \(\mathbb{R}^2\) or far from it. We remark that under the restrictions \(\alpha \geq -1/2\) and \(\sigma < \alpha + 1\), an upper bound for \(K^{\alpha,\sigma}(x, y)\) was obtained recently in [4, Proposition 5.1].

The description of \(K^{\alpha,\sigma}(x, y)\) from Theorem 2.1 enables a direct analysis of the potential operator \(I^{\alpha,\sigma}\). In particular, it allows us to characterize those \(1 \leq p, q \leq \infty\), for which \(I^{\alpha,\sigma}\) is \(L^p - L^q\) bounded, see also Fig. 1 below.

**Theorem 2.2** Let \(\alpha > -1\), \(\sigma > 0\) and \(1 \leq p, q \leq \infty\).

(a) If \(\alpha \geq -1/2\), then \(I^{\alpha,\sigma}\) is bounded from \(L^p(d\mu_\alpha)\) to \(L^q(d\mu_\alpha)\) if and only if

\[
\frac{1}{p} - \frac{\sigma}{\alpha + 1} \leq \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha + 1} \quad \text{and} \quad \left(\frac{1}{p}, \frac{1}{q}\right) \notin \left\{ \left(\frac{\sigma}{\alpha + 1}, 0\right), \left(1, 1 - \frac{\sigma}{\alpha + 1}\right) \right\}.
\]

(b) If \(\alpha < -1/2\), then \(I^{\alpha,\sigma}\) is bounded from \(L^p(d\mu_\alpha)\) to \(L^q(d\mu_\alpha)\) if and only if

\[
\frac{1}{p} + \frac{\sigma}{\alpha} \leq \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha + 1}.
\]

Note that the sufficiency part of Theorem 2.2 (a) was essentially known to the authors earlier, even in the multi-dimensional case, see [9, Theorem 4.1]. Here, however, we give a direct proof which offers a better insight into the structure of \(I^{\alpha,\sigma}\). The necessity part, as well as item (b) in Theorem 2.2, is new. It seems a bit surprising that the conditions in (a) and (b) are different, since many known results related to the system \(\{\ell^\alpha_n\}\) are homogeneous in \(\alpha > -1\), without any ‘phase shift’ at \(\alpha = -1/2\); see for instance [12, Theorem 4.1] and [12, Corollary 4.2].

![Fig. 1](image_url) Optimal sets of \(\left(\frac{1}{p}, \frac{1}{q}\right)\) for which \(I^{\alpha,\sigma}\) is \(L^p - L^q\) bounded when \(\sigma < \alpha + 1\); (a) the case of \(\alpha \geq -1/2\), (b) the case of \(\alpha < -1/2\).
2.2 Laguerre Function Setting of Hermite Type

This Laguerre context is derived from the previous one by modifying the Laguerre functions \( \ell_n^\alpha \) so as to make the resulting system orthonormal with respect to Lebesgue measure \( dx \) in \( \mathbb{R}_+ \). Thus, given a parameter \( \alpha > -1 \), we consider the functions

\[
\varphi_n^\alpha(x) = x^{\alpha+1/2} \ell_n^\alpha(x), \quad x > 0.
\]

Then the system \( \{\varphi_n^\alpha : n \geq 0\} \) is an orthonormal basis in \( L^2(dx) \). The associated ‘Laplacian’ is

\[
L_a^H = -\frac{d^2}{dx^2} + x^2 + \frac{(\alpha - 1/2)(\alpha + 1/2)}{x^2},
\]

and we have \( L_a^H \varphi_n^\alpha = (4n + 2\alpha + 2)\varphi_n^\alpha \). The Laguerre heat semigroup \( \exp(-tL_a^H) \), generated by means of the natural self-adjoint extension of \( L_a^\alpha \) in this context, has an integral representation. The associated heat kernel is \( (xy)^{\alpha+1/2}G_{\alpha}^t(x, y), x, y > 0 \), see Eq. 1.

For \( \sigma > 0 \), consider the potential operator

\[
I_{\alpha,\sigma}^H f(x) = \int_0^\infty K_{\alpha,\sigma}^H(x, y)f(y)dy, \quad x > 0,
\]

where

\[
K_{\alpha,\sigma}^H(x, y) = (xy)^{\alpha+1/2}K_{\alpha,\sigma}(x, y), \quad x, y > 0. \tag{2}
\]

Because of this simple link between the two potential kernels, Theorem 2.1 gives qualitatively sharp estimates also for \( K_{\alpha,\sigma}^H(x, y) \). Then, taking into account the behavior of the kernel for \( \alpha < -1/2 \) and \( x \) and \( y \) small, it is not hard to see that \( I_{\alpha,\sigma}^H \) can be well defined on \( L^p \) only if \( \frac{1}{p} < \alpha + 3/2 \). In fact, when \( \alpha < -1/2 \) we have \( L^p(dx) \subset \text{Dom} I_{\alpha,\sigma}^H \) if and only if \( p \in (2/(2\alpha + 3), \infty) \) (here \( \text{Dom} I_{\alpha,\sigma}^H \) denotes the natural domain of the integral operator \( I_{\alpha,\sigma}^H \)). Note that this case is qualitatively different from the case \( \alpha \geq -1/2 \), see the comments preceding [9, Theorem 3.1].

The following result gives a complete and sharp description of \( L^p - L^q \) boundedness of \( I_{\alpha,\sigma}^H \). It reveals that for \( \alpha \geq -1/2 \), \( I_{\alpha,\sigma}^H \) behaves exactly like \( I^{-1/2,\sigma} \), see Fig. 1 (a) with \( \alpha = -1/2 \), and thus like the Hermite potential operator \( \mathcal{I}^{\sigma} \) (see the case of \( I_{\alpha,\sigma}^{-1/2,\sigma} \) in Theorem 2.6 below). On the other hand, for \( \alpha < -1/2 \) the \( L^p - L^q \) behavior of \( I_{\alpha,\sigma}^H \) is more subtle, and partially this is caused by the restriction on \( p \) mentioned above. In particular, the region characterizing those \( (\frac{1}{p}, \frac{1}{q}) \) for which \( I_{\alpha,\sigma}^H \) is \( L^p - L^q \) bounded may take various peculiar shapes, see Fig. 2 below.

**Theorem 2.3** Let \( \alpha > -1, \sigma > 0 \) and \( 1 \leq p, q \leq \infty \).

(a) If \( \alpha \geq -1/2 \), then \( I_{\alpha,\sigma}^H \) is bounded from \( L^p(dx) \) to \( L^q(dx) \) if and only if

\[
\frac{1}{p} - 2\sigma \leq \frac{1}{q} < \frac{1}{p} + 2\sigma \quad \text{and} \quad \left( \frac{1}{p}, \frac{1}{q} \right) \notin \{(2\sigma, 0), (1, 1 - 2\sigma)\}.
\]

(b) If \( \alpha < -1/2 \) and \( p > 2/(2\alpha + 3) \), then \( I_{\alpha,\sigma}^H \) is bounded from \( L^p(dx) \) to \( L^q(dx) \) if and only if

\[
\frac{1}{p} - 2\sigma \leq \frac{1}{q} < \frac{1}{p} + 2\sigma \quad \text{and} \quad \frac{1}{q} > -\alpha - \frac{1}{2}.
\]

Note that the sufficiency part of Theorem 2.3 (a) was known earlier, even in the multi-dimensional case, see [9, Theorem 3.1]. Apart from that, the result is new.
Fig. 2  Shapes of optimal sets of \((1/p, 1/q)\) for which \(I^p_{\alpha,\sigma}H\) is \(L^p - L^q\) bounded when \(\sigma < 1/2\) and \(\alpha < -1/2\); (b1) the case of \(\sigma \geq \alpha + 1\) and \(\sigma > -\alpha/2 - 1/4\), (b2) the case of \(-\alpha/2 - 1/4 < \sigma < \alpha + 1\), (b3) the case of \(\alpha + 1 \leq \sigma \leq -\alpha/2 - 1/4\), (b4) the case of \(\sigma < \alpha + 1\) and \(\sigma \leq -\alpha/2 - 1/4\). The particular choices of \(\alpha\) and \(\sigma\) are different for each picture.

2.3 Dunkl-Laguerre Setting

Let \(\alpha > -1\). The generalized Hermite functions are given by

\[
h^{\alpha}_n(x) = \frac{1}{\sqrt{2}} \begin{cases} (-1)^{n/2} \ell^{\alpha}_{n/2}(x), & n \text{ even}, \\ (-1)^{(n-1)/2} x \ell^{\alpha+1}((n-1)/2)(x), & n \text{ odd}, \end{cases}
\]

where \(\ell^{\alpha}_n\) are the Laguerre functions of convolution type naturally extended to \(\mathbb{R}\) as even functions. The system \(\{h^{\alpha}_n : n \geq 0\}\) is an orthonormal basis in \(L^2(dw^{\alpha})\), where \(w^{\alpha}\) is the even extension of \(\mu^{\alpha}\),

\[
dw^{\alpha}(x) = |x|^{2\alpha+1} dx, \quad x \in \mathbb{R}.
\]

Notice that expansions of even functions with respect to \(\{h^{\alpha}_n\}\) reduce to expansions with respect to the Laguerre system \(\{\ell^{\alpha}_n\}\). The \(h^{\alpha}_n\) are eigenfunctions of the one-dimensional Dunkl harmonic oscillator

\[
L^{D\alpha}_x f(x) = L_\alpha f(x) + (\alpha + 1/2) \frac{f(x) - f(-x)}{x^2}
\]

(notice that this is a differential-difference ‘Laplacian’) and one has \(L^{D\alpha}_x h^{\alpha}_n = (2n + 2\alpha + 2)h^{\alpha}_n\). We use the same symbol to denote the natural, in this situation, self-adjoint extension of \(L^{D\alpha}_x\).

For \(\alpha = -1/2\) this setting coincides with that of classical Hermite function expansions. Note that the parameter \(\alpha\) represents the so-called (in the Dunkl theory) multiplicity function. This function is trivial when \(\alpha = -1/2\), positive when \(\alpha > -1/2\), and negative for \(\alpha < -1/2\). The latter case is exotic in the sense that positivity of the multiplicity function is crucial in several important aspects of the Dunkl theory. As we shall see, the positivity turns out to be significant also in our developments.

The Dunkl-Laguerre heat semigroup \(\{\exp(-tL^{D\alpha}_x)\}\) possesses an integral representation (with integration against \(dw^{\alpha}\)), and the integral kernel of \(\exp(-tL^{D\alpha}_x)\) is

\[
G^{\alpha,D}_t(x, y) = \frac{1}{2} (\sinh 2t)^{-\sigma-1} \exp \left( -\frac{1}{2} \coth(2t)(x^2 + y^2) \right) \Phi^{\alpha}_t \left( \frac{xy}{\sinh 2t} \right), \quad x, y \in \mathbb{R},
\]

where \(\Phi^{\alpha}_t\) is a continuous function on the real line defined by

\[
\Phi^{\alpha}_t(u) := |u|^{-\alpha} \left[ I_\alpha(|u|) + \text{sgn}(u) I_{\alpha+1}(|u|) \right],
\]

\(\text{sgn}\) indicating the signum function.
with the value $\Phi_\alpha(0) = 2^{-\alpha}/\Gamma(\alpha + 1)$ understood in the limiting sense. By the standard
asymptotics (cf. [5, (5.16.4), (5.16.5)])

$$I_v(u) \simeq u^\alpha, \quad u \to 0^+, \quad \text{and} \quad I_v(u) \simeq u^{-1/2}e^u, \quad u \to \infty,$$

and strict positivity of $I_v(u)$, $u > 0$, it is straightforward to see that $|\Phi_\alpha(u)| \lesssim |u|^{-\alpha}I_\alpha(|u|)$,
$u \in \mathbb{R}$, and $\Phi_\alpha(u) \simeq u^{-\alpha}I_\alpha(u)$, $u > 0$. This together with Eq. 1 implies

$$|G_{\alpha,D}^\alpha(x, y)| \lesssim |x+y|^{-\alpha}I_\alpha(|x+y|), \quad x, y \in \mathbb{R},$$

(5)

and $G_{\alpha,D}^\alpha(x, y) \simeq G_\alpha^\alpha(x, y)$, $x > 0$. This together with Eq. 1 implies

$$|G_{\alpha,D}^\alpha(x, y)| \lesssim |x+y|^{-\alpha}I_\alpha(|x+y|), \quad x, y \in \mathbb{R},$$

(6)

A more detailed analysis (see Section 3.2 below) reveals that $G_{\alpha,D}^\alpha(x, y)$ is strictly positive
when either $\alpha \geq -1/2$ or $xy \geq 0$, but for $\alpha < -1/2$ and $xy < 0$ it attains also negative
values. It seems that this phenomenon has not been properly noticed before.

As in the previous settings, for $\sigma > 0$ we consider the potential operator

$$I_{\alpha,\sigma}^D f(x) = \int_{-\infty}^{\infty} K_{\alpha,\sigma}^D(x, y) f(y) \, dw_\alpha(y), \quad x \in \mathbb{R},$$

where the potential kernel is expressed via $G_{\alpha,D}^\alpha(x, y)$ as

$$K_{\alpha,\sigma}^D(x, y) = \frac{1}{\Gamma(\sigma)} \int_0^{\infty} G_{\alpha,D}^\alpha(x, y)t^{\sigma-1} \, dt, \quad x, y \in \mathbb{R}.$$

In view of Eqs. 5 and 6, we have

$$|K_{\alpha,\sigma}^D(x, y)| \lesssim |x+y|^{-\alpha}I_\alpha(|x+y|), \quad x, y \in \mathbb{R},$$

(7)

$$K_{\alpha,\sigma}^D(x, y) \simeq K_\alpha^\alpha(x, y), \quad x, y > 0.$$

(8)

These two relations deliver enough information to obtain a characterization of $L^p - L^q$ boundedness of $I_{\alpha,\sigma}^D$. Nevertheless, the question of an exact description of $K_{\alpha,\sigma}^D(x, y)$ is an
important problem in its own right. The result below provides qualitatively sharp estimates
of $K_{\alpha,\sigma}^D(x, y)$ for $\alpha > -1/2$ (the case of a positive multiplicity function).

**Theorem 2.4** Let $\alpha > -1/2$ and let $\sigma > 0$. The following estimates hold uniformly in $x, y \in \mathbb{R}$.

(A) Assume that $xy \geq 0$, i.e. $x$ and $y$ have the same sign.

(A1) If $|x| + |y| \leq 1$, then

$$K_{\alpha,\sigma}^D(x, y) \simeq \chi_{\sigma > \alpha + 1} + \chi_{\sigma = \alpha + 1} \log \frac{1}{|x+y|} + (|x| + |y|)^{-2\sigma-1}$$

$$\times \left\{ \begin{array}{ll}
|x-y|^{2\sigma-1}, & \sigma < 1/2, \\
1 + \log \frac{|x+y|}{|x-y|}, & \sigma = 1/2, \\
(|x| + |y|)^{2\sigma-1}, & \sigma > 1/2.
\end{array} \right.$$

(A2) If $|x| + |y| > 1$, then

$$K_{\alpha,\sigma}^D(x, y) \simeq (|x| + |y|)^{-2\sigma-1} \exp(-c|x-y||x+y|)$$

$$\times \left\{ \begin{array}{ll}
|x-y|^{2\sigma-1}, & \sigma < 1/2, \\
1 + \log \frac{1}{|x-y||x+y|}, & \sigma = 1/2, \\
(|x| + |y|)^{1-2\sigma}, & \sigma > 1/2.
\end{array} \right.$$
(B) Assume that $xy < 0$, i.e. $x$ and $y$ have opposite signs.

(B1) If $|x| + |y| \leq 1$, then

$$K_{D_D}^{\alpha, \sigma}(x, y) \simeq \chi_{[\sigma > \alpha + 1]} \cdot \chi_{[\sigma = \alpha + 1]} \cdot \log \frac{1}{|x| + |y|} + (|x| + |y|)^{-2\alpha - 1}(|x| + |y|)^{2\sigma - 1}.$$ 

(B2) If $|x| + |y| > 1$, then

$$K_{D_D}^{\alpha, \sigma}(x, y) \simeq (|x| + |y|)^{-2\alpha - 1} \exp \left(-c|x - y|(|x| + |y|)\right) \times (|x| + |y|)^{1 - 2\sigma}(|x| + |y|)^{-2\sigma}. $$

For the sake of completeness, we recall that (see [10, Theorem 2.4])

$$K_{D_D}^{-1/2, \sigma}(x, y) \simeq \exp \left(-c|x - y|(|x| + |y|)\right) \begin{cases} 1 + \log^{+} \left(\frac{|x - y|}{(|x| + |y|)}\right), & \sigma = 1/2, \\ 1 + |x + y|^{1 - 2\sigma}, & \sigma > 1/2, \end{cases}$$

uniformly in $x, y \in \mathbb{R}$. When $xy \geq 0$, this agrees with the estimates of Theorem 2.4 (A) taken with $\alpha = -1/2$. On the other hand, in case $xy < 0$ the exponential factor in Eq. 9 possesses essentially better decay if compared with the exponential factor in Theorem 4 (B2). In particular, on the line $y = -x$ the right-hand side in Eq. 9 has an exponential decay, which is not the case of the right-hand side in (B2). This reflects a discontinuity in the behavior of $\Phi_{\alpha}(u)$ as $\alpha \to (-1/2)^+$ (exponential growth/decay when $u \to -\infty$), see Section 3.2 below.

When $\alpha < -1/2$ (the case of a negative multiplicity function), no general sharp estimates in the spirit of Theorem 2.4 are possible, because $K_{D_D}^{\alpha, \sigma}(x, y)$ attains also negative values. In fact, we have the following result (the proof can be found in Section 3.2).

**Proposition 2.5** Let $-1 < \alpha < -1/2$ and $\sigma > 0$ be fixed. There exists an unbounded set $\mathcal{D} \subset \{(x, y) : xy < 0\} \subset \mathbb{R}^2$ of positive Lebesgue measure such that

$$K_{D_D}^{\alpha, \sigma}(x, y) < 0, \quad (x, y) \in \mathcal{D}.$$ 

Finally, we establish a sharp description of $L^p - L^q$ boundedness of $I_{D_D}^{\alpha, \sigma}$. It occurs that $I_{D_D}^{\alpha, \sigma}$ behaves exactly in the same way as $I_{D_D}^{\alpha, \sigma}$, see Fig. 1. The proof is based on Eqs. 7 and 8 and Theorem 2.2. Perhaps a bit unexpectedly, Theorem 2.4 is not needed here.

**Theorem 2.6** Let $\alpha > -1, \sigma > 0$ and $1 \leq p, q \leq \infty$.

(a) If $\alpha \geq -1/2$, then $I_{D_D}^{\alpha, \sigma}$ is bounded from $L^p(dw_{\alpha})$ to $L^q(dw_{\alpha})$ if and only if

$$\frac{1}{p} - \frac{\sigma}{\alpha + 1} \leq \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha + 1} \quad \text{and} \quad \left(\frac{1}{p}, \frac{1}{q}\right) \notin \left\{\left(\frac{\sigma}{\alpha + 1}, 0\right), \left(1, 1 - \frac{\sigma}{\alpha + 1}\right)\right\}.$$ 

(b) If $\alpha < -1/2$, then $I_{D_D}^{\alpha, \sigma}$ is bounded from $L^p(dw_{\alpha})$ to $L^q(dw_{\alpha})$ if and only if

$$\frac{1}{p} + \frac{\sigma}{\alpha} \leq \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha + 1}. $$
Note that the result in the Hermite case $\alpha = -1/2$ was known earlier, see [10] and references given there. Essentially, also the sufficiency part of Theorem 2.6 (a) was known before, even in the multi-dimensional setting, see [9, Theorem 6.1]. The rest of the theorem is new.

**Remark 2.7** The estimates of Theorem 2.1 specified to $\alpha = \pm 1/2$ and the estimates Eq. 9 for the harmonic oscillator potential kernel are consistent in the following way. Theorem 2.1 implies Eq. 9 for $xy > 0$, as can be verified by means of the relation

$$2K^{−1/2,\sigma} D(x, y) = K^{−1/2,\sigma}(x, y) + xyK^{1/2,\sigma}(x, y), \quad x, y > 0.$$  

On the other hand, Eq. 9 implies the bounds of Theorem 2.1 specified to $\alpha = -1/2$, since

$$K^{−1/2,\sigma}(x, y) = K^{−1/2,\sigma} D(x, y) + K^{−1/2,\sigma} D(-x, y), \quad x, y > 0.$$  

### 3 Estimates of the Potential Kernels

In this section we prove Theorems 2.1 and 2.4, and also Proposition 2.5. We begin with two auxiliary technical results that provide sharp description of the behavior of the integrals $J^A(T, S)$ and $E^A(T, S)$ defined below. These are essentially [10, Lemmas 2.1–2.3]. Here we give slightly more general statements, nevertheless their proofs are almost the same as those in [10].

Let

$$J^A(T, S) := \int^S_T t^A \exp(-t) \, dt, \quad 0 \leq T \leq S \leq \infty, \quad T < \infty,$$

$$E^A(T, S) := \int^1_0 t^A \exp\left(-Tt^{-1} - St\right) \, dt, \quad 0 \leq T, S < \infty.$$

**Lemma 3.1** ([10, Lemma 2.1, Lemma 2.2]) Let $A \in \mathbb{R}$, $\beta > 1$ and $\gamma > 0$ be fixed. The following estimates hold uniformly in $0 \leq T \leq S \leq \infty$, $T < \infty$.

(a) If $S \leq \beta T$, then

$$J^A(T, S) \simeq T^A (S - T) \exp(-cT).$$

(b) If $S > \beta T$ and $T \geq \gamma$, then

$$J^A(T, S) \simeq T^A \exp(-T).$$

(c) If $S \geq \beta \gamma$ and $T < \gamma$ (this implies $S > \beta T$), then

$$J^A(T, S) \simeq \begin{cases} T^A + 1, & A < -1, \\ 1 + \log^+(1/T), & A = -1, \\ 1, & A > -1. \end{cases}$$

(d) If $S > \beta T$ and $S < \beta \gamma$, then

$$J^A(T, S) \simeq \begin{cases} T^A + 1, & A < -1, \\ \log(S/T), & A = -1, \\ S^A + 1, & A > -1. \end{cases}$$
Lemma 3.2 ([10, Lemma 2.3]) Let $A \in \mathbb{R}$ be fixed. Then
\[
E_A(T, S) \simeq \exp \left( -c \sqrt{T(T \lor S)} \right) \begin{cases} 
T^{A+1}, & A < -1, \\
1 + \log^+ \frac{1}{T^{(1-A)/2}}, & A = -1, \\
(S \lor 1)^{-A-1}, & A > -1,
\end{cases}
\]
uniformly in $T, S \geq 0$.

3.1 Estimates of the Laguerre Potential Kernels

Proving Theorem 2.1 requires some further preparation. The plan is to estimate $K^{\alpha, \sigma}(x, y)$ first in terms of $J_A(T, S)$ and $E_A(T, S)$, and then to apply Lemmas 3.1 and 3.2. Let
\[
G_t(x, y) = \frac{1}{(2\pi \sinh 2t)^{1/2}} \exp \left( -\frac{1}{4} \left[ \tanh(t) (x + y)^2 + \coth(t) (x - y)^2 \right] \right)
\]
be the heat kernel associated with one-dimensional Hermite function expansions; note that $G_t(x, y) = G_{t}^{1/2,D}(x, y)$. The behavior of $G_t^\alpha(x, y)$ can be described in a sharp way in terms of $G_t(x, y)$.

Lemma 3.3 Let $\alpha > -1$. Then
\[
G_t^\alpha(x, y) \simeq (xy \lor \sinh 2t)^{-\alpha-1/2} G_t(x, y)
\]
uniformly in $x, y > 0$ and $t > 0$.

Proof Elementary exercise based on the asymptotics Eq. 4.

Lemma 3.4 Let $\alpha > -1$. The following estimates hold uniformly in $x, y > 0$.

(a) If $xy \leq 1$, then
\[
K^{\alpha, \sigma}(x, y) \simeq \exp \left( -c(x + y)^2 \right) + (x + y)^{2\sigma - 2\alpha - 2} J_{\alpha-\sigma} \left( c_1(x + y)^2, c_2 \frac{(x+y)^2}{xy} \right) + (xy)^{\sigma-\alpha-1} E_{\sigma-3/2} \left( c \frac{(x-y)^2}{xy}, cxy(x+y)^2 \right),
\]
where $c_1 < c_2$ are positive constants, independent of $x$ and $y$, that may be different in the lower and upper estimate.

(b) If $xy > 1$, then
\[
K^{\alpha, \sigma}(x, y) \simeq \exp \left( -c(x + y)^2 \right) + (xy)^{-\alpha-1/2} E_{\sigma-3/2} \left( c(x - y)^2, c(x+y)^2 \right).
\]

Proof In view of Lemma 3.3,
\[
K^{\alpha, \sigma}(x, y) \simeq \int_0^\infty (xy \lor \sinh 2t)^{-\alpha-1/2} G_t(x, y) t^{\sigma-1} dt.
\]
To proceed, we get rid of the maximum above by splitting the integral according to the point $p(xy)$, where the function $p(r)$ is defined by the identity $\sinh 2p(r) = r, r > 0$. Notice that
\[
p(xy) \simeq \begin{cases} 
xy, & xy \leq 1, \\
\log 2xy, & xy > 1.
\end{cases}
\]
Taking into account the explicit form of $G_t(x, y)$, we can write
\[
K^{\alpha, \sigma}(x, y) \\
\simeq (xy)^{-\alpha - 1/2} \int_0^{p(xy)} (\sinh 2t)^{-1/2} t^{\sigma - 1} \exp \left( -\frac{1}{4} [\tanh(t) (x + y)^2 + \coth(t) (x - y)^2] \right) dt \\
+ \int_p^{\infty} (\sinh 2t)^{-\alpha - 1} t^{\sigma - 1} \exp \left( -\frac{1}{2} \coth(2t) (x^2 + y^2) \right) dt \\
= I_0 + I_\infty.
\]

We first prove (a). To this end assume that $xy \leq 1$. Since $p(xy) \lesssim xy$, we have
\[
I_0 \simeq (xy)^{-\alpha - 1/2} \int_0^{p(xy)} t^{\sigma - 3/2} \exp \left( -c \left[ t^{-1} (x - y)^2 + t (x + y)^2 \right] \right) dt.
\]
Changing the variable of integration, we get
\[
I_0 \simeq (xy)^{-\alpha - 1/2} p(xy)^{\sigma - 1/2} \int_0^{1} s^{\sigma - 3/2} \exp \left( -c \left[ s^{-1} (x - y)^2 + sp(xy)(x + y)^2 \right] \right) ds.
\]
Since $p(xy) \simeq xy$, we conclude that
\[
I_0 \simeq (xy)^{\sigma - \alpha - 1} E_{\sigma - 3/2} \left( \frac{(x - y)^2}{xy}, cxy(x + y)^2 \right).
\]
Next, we estimate $I_\infty$. We split this integral according to $C$ satisfying $2p(r) \leq Cr$, $r \leq 1$. This bound actually holds with $C = 1$, in view of the inequality $\sinh t > t$, $t > 0$. Then we obtain
\[
I_\infty \simeq \int_p^{1} t^{\sigma - 2} \exp \left( -c \frac{t}{7} (x^2 + y^2) \right) dt + \exp \left( -c(x^2 + y^2) \right) \int_1^{\infty} t^{\sigma - 1} e^{-2(\alpha + 1)t} dt \\
= I_{\infty, 1} + I_{\infty, 2}.
\]
The treatment of $I_{\infty, 2}$ is obvious since the integral over $(1, \infty)$ is a finite constant. To deal with $I_{\infty, 1}$ we change the variable of integration and find that
\[
I_{\infty, 1} \simeq (x^2 + y^2)^{\sigma - \alpha - 1} \int_{c(x^2+y^2)}^{c(x^2+y^2)} s^{\alpha - \sigma} e^{-s} ds.
\]
Since $p(xy) \simeq xy$ and $x^2 + y^2 \simeq (x + y)^2$, we infer that
\[
I_\infty \simeq (x + y)^{2\sigma - 2\alpha - 2} J_{\alpha - \sigma} \left( c_1 (x + y)^2, c_2 \frac{(x + y)^2}{xy} \right) + \exp \left( -c(x + y)^2 \right),
\]
where $c_1 < c_2$ are positive constants that may differ in the lower and upper estimate. Item (a) follows.

To prove (b), assume that $xy > 1$. Consider first $I_\infty$. Since $p(xy) \gtrsim \log 2xy$, we can write
\[
I_\infty \simeq \exp \left( -c(x^2 + y^2) \right) \int_1^{\infty} t^{\sigma - 1} e^{-2(\alpha + 1)t} dt.
\]
But $t^{\sigma - 1} e^{-2(\alpha + 1)t} \simeq e^{-ct}$ for $t \geq p(1)$, so, taking into account that actually $p(xy) \simeq \log 2xy$, we see that
\[
(xy)^{-c_1} \lesssim \int_{p(xy)}^{\infty} t^{\sigma - 1} e^{-2(\alpha + 1)t} dt \lesssim (xy)^{-c_1}.
\]
where $c_3$ and $c_4$ are positive constants. Thus
\[ I_\infty \simeq \exp \left( -c(x+y)^2 \right). \]

Finally, we analyze $I_0$. We split this integral getting
\[ I_0 \simeq (xy)^{-\alpha-1/2} \int_0^p t^{\sigma-3/2} \exp \left( -c \left[ t^{-1}(x-y)^2 + t(x+y)^2 \right] \right) dt \]
\[ + (xy)^{-\alpha-1/2} \exp \left( -c(x^2+y^2) \right) \int_p^\infty t^{\sigma-1} e^{-t} dt \]
\[ \equiv I_{0,1} + I_{0,2}. \]

Clearly,
\[ I_{0,2} \lesssim (xy)^{-\alpha-1/2} \exp \left( -c(x^2+y^2) \right) \int_p^\infty t^{\sigma-1} e^{-t} dt \simeq \exp \left( -c(x+y)^2 \right). \]

Further, changing the variable of integration we see that
\[ I_{0,1} \simeq (xy)^{-\alpha-1/2} E_{\sigma-3/2} \left( c(x-y)^2, c(x+y)^2 \right). \]

Altogether, the above estimates justify item (b).

We are now in a position to prove Theorem 2.1.

**Proof of Theorem 2.1** We distinguish three cases.

**Case 1: $xy > 1$.** Notice that in this case $x+y > 1$, so we must show that
\[ K^{\alpha,\sigma}(x,y) \simeq (x+y)^{-2\alpha-1} \exp \left( -c|x-y|(x+y) \right) \begin{cases} |x-y|^{2\sigma-1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{1}{|x-y|(x+y)}, & \sigma = 1/2, \\ (x+y)^{1-2\sigma}, & \sigma > 1/2. \end{cases} \]

By Lemma 3.4 we know that
\[ K^{\alpha,\sigma}(x,y) \simeq \exp \left( -c(x+y)^2 \right) + (xy)^{-\alpha-1/2} E_{\sigma-3/2} \left( c(x-y)^2, c(x+y)^2 \right). \]

Here $E_{\sigma-3/2}$ can be estimated by means of Lemma 3.2, we get
\[ K^{\alpha,\sigma}(x,y) \simeq \exp \left( -c(x+y)^2 \right) + (xy)^{-\alpha-1/2} \exp \left( -c|x-y|(x+y) \right) \begin{cases} |x-y|^{2\sigma-1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{1}{|x-y|(x+y)}, & \sigma = 1/2, \\ (x+y)^{1-2\sigma}, & \sigma > 1/2. \end{cases} \]

In this sum the first term can be neglected since, as easily verified, it contributes to the relation $\simeq$ no more than the second one. Further, the factor $(xy)^{-\alpha-1/2}$ can be replaced by $(x+y)^{-2\alpha-1}$. This is clear when $x$ and $y$ are comparable. In the opposite case, it suffices to take into account the bounds $(x+y)^2 \simeq |x-y|(x+y) \gtrsim xy$, recall that $xy > 1$ and use the exponential decay. The conclusion follows.

**Case 2: $xy \leq 1$ and $x+y > 3$.** Again, our aim is to prove Eq. 11. Observe that in this case $x$ and $y$ are non-comparable. For symmetry reasons, we may assume that $x > 2y$. Thus the estimate to be shown is
\[ K^{\alpha,\sigma}(x,y) \simeq x^{-2\alpha-1} \exp \left( -cx^2 \right) \begin{cases} x^{2\sigma-1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{1}{x^\sigma}, & \sigma = 1/2, \\ x^{1-2\sigma}, & \sigma > 1/2. \end{cases} \]
But $x > 1$, so it is enough to check that

$$K^{\alpha, \sigma}(x, y) \lesssim \exp\left(-c x^2\right).$$  \hspace{1cm} (12)

By Lemma 3.4,

$$K^{\alpha, \sigma}(x, y) \lesssim \exp\left(-c(x + y)^2\right) + (x + y)^{2\sigma - 2\alpha - 2} J_{\alpha - \sigma} \left(c_1 (x + y)^2, c_2 (x + y^2)\right) + (xy)^{\sigma - \alpha - 1} E_{\sigma - 3/2} \left(c \frac{(x - y)}{xy}, cxy(x + y)^2\right) \equiv U_1(x, y) + U_2(x, y) + U_3(x, y).$$

Here $U_1$ agrees with the right-hand side of Eq. 12, so it suffices to bound suitably $U_2$ and $U_3$ from above. Observe that $U_2$ can be estimated from above by replacing the second argument of $J_{\alpha - \sigma}$ by $\infty$. Then, taking into account that $c_1 (x + y)^2 \gtrsim x^2 > 1$, Lemma 3.1 (b) shows that

$$U_2(x, y) \lesssim x^{2\sigma - 2\alpha - 2} x^{2\sigma - 2\alpha} \exp\left(-c_1 x^2\right) < \exp\left(-c_1 x^2\right).$$

Thus this term also fits to Eq. 12 contributing in the sense of $\lesssim$ no more than the first one. Finally, $U_3$ can be estimated from above by replacing the second argument of $E_{\sigma - 3/2}$ by 0. Then, with the aid of Lemma 3.2 and the relations $|x - y| \approx x + y \approx x > 1$ we get

$$U_3(x, y) \lesssim (xy)^{\sigma - \alpha - 1} \exp\left(-\tilde{c} \frac{x^2}{xy}\right) \begin{cases} \left(\frac{x^2}{xy}\right)^{\sigma - 1/2}, & \sigma < 1/2, \\ 1, & \sigma \geq 1/2 \end{cases}

\lesssim \exp\left(-\tilde{c} x^2/2\right),$$

the last estimate being a consequence of the inequalities $xy \leq 1$ and $x > 1$. Now Eq. 12 follows.

**Case 3: $xy \leq 1$ and $x + y \leq 3$.** In this case $x \leq 3$ and $y \leq 3$. Since the estimates of (i) and (ii) of Theorem 2.1 essentially coincide for $x$ and $y$ separated from 0 and $\infty$, what we need to prove is

$$K^{\alpha, \sigma}(x, y) \approx X_{[\sigma > \alpha + 1]}(x, y) + X_{[\sigma = \alpha + 1]}(x, y) \log^+ \frac{1}{x + y} + (x + y)^{-2\sigma + 1} \begin{cases} |x - y|^{2\sigma - 1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{x + y}{|x - y|}, & \sigma = 1/2, \\ (x + y)^{2\sigma - 1}, & \sigma > 1/2. \end{cases}$$  \hspace{1cm} (13)

We keep using the description of $K^{\alpha, \sigma}$ in terms of $U_1$, $U_2$ and $U_3$, see above. Observe that

$$U_1(x, y) \approx 1.$$

To estimate $U_2$ we apply Lemma 3.1 (b)-(d). After some elementary manipulations, taking into account that $x$ and $y$ stay bounded, we get

$$U_2(x, y) \approx \begin{cases} (x + y)^{2\sigma - 2\alpha - 2}, & \sigma < \alpha + 1, \\ 1 + \log^+ \frac{1}{x + y}, & \sigma = \alpha + 1, \\ 1, & \sigma > \alpha + 1. \end{cases}$$  \hspace{1cm} (14)

Considering $U_3$, by the boundedness of $x$ and $y$ and the structure of the integral $E_{\sigma - 3/2}$ we may assume that its second argument is 0. Then, in view of Lemma 3.2, we have

$$U_3(x, y) \approx \approx (xy)^{-\alpha - 1/2} \exp\left(-c \frac{(x - y)^2}{xy}\right) \begin{cases} |x - y|^{2\sigma - 1}, & \sigma < 1/2, \\ 1 + \log^+ \frac{xy}{(x - y)^2}, & \sigma = 1/2, \\ (xy)^{\sigma - 1/2}, & \sigma > 1/2. \end{cases}$$
We claim that, excluding the exponential factor, all the products $xy$ here can be replaced by $(x + y)^2$. Indeed, this is clear when $x$ and $y$ are comparable. In the opposite case, say when $x > 2y$, $\log^+$ is controlled by a constant, so its argument can be replaced by $(x + y)^2/(x - y)^2 \simeq 1$. Further, we have $(x - y)^2/xy \simeq x/y$, and given any $\gamma \in \mathbb{R}$ and $C > 0$ fixed

$$(xy)^\gamma \exp\left(-C \frac{x}{y}\right) = x^{2\gamma} \left(\frac{x}{y}\right)^{-\gamma} \exp\left(-C \frac{x}{y}\right) \simeq (x + y)^{2\gamma} \exp\left(-C \frac{x}{y}\right).$$

The claim follows and we conclude that

$$U_3(x, y) \simeq (x + y)^{-2\alpha - 1} \exp\left(-\frac{x - y}{xy}\right) \begin{cases} |x - y|^{2\alpha - 1}, & \sigma < 1/2, \\ 1 + \log \frac{x + y}{|x - y|}, & \sigma = 1/2, \\ (x + y)^{2\alpha - 1}, & \sigma > 1/2. \end{cases} \quad (15)$$

Assume that $x \simeq y$. Then the exponential factor on the right-hand side above is roughly a constant. Moreover, $U_3(x, y) \gtrsim (x + y)^{2\alpha - 2\alpha - 2}$. Therefore, in view of Eqs. 14 and 15, for comparable $x$ and $y$

$$U_2(x, y) + U_3(x, y) \simeq \chi_{\sigma > \alpha + 1} + \chi_{\sigma = \alpha + 1} \left(1 + \log^+ \frac{1}{x + y}\right) + (x + y)^{-2\alpha - 1} \begin{cases} |x - y|^{2\alpha - 1}, & \sigma < 1/2, \\ 1 + \log \frac{x + y}{|x - y|}, & \sigma = 1/2, \\ (x + y)^{2\alpha - 1}, & \sigma > 1/2. \end{cases}$$

Notice that the right-hand side here is separated from 0, and this remains true even without the second term. Thus $U_1(x, y) \lesssim U_2(x, y) + U_3(x, y)$ and the second term can be replaced by $\chi_{\sigma = \alpha + 1} \log^+ \frac{1}{x + y}$. We see that Eq. 13 holds when $x \simeq y$.

Finally, let $x$ and $y$ be non-comparable. For symmetry reasons, we may assume that $x > 2y$. Then the desired estimate Eq. 13 takes the form

$$K^{\alpha, \sigma}(x, y) \simeq \chi_{\sigma > \alpha + 1} + \chi_{\sigma = \alpha + 1} \log^+ \frac{1}{x} + x^{2\sigma - 2\alpha - 2}. \quad (16)$$

On the other hand, from Eqs. 14 and 15 we have

$$U_2(x, y) + U_3(x, y) \simeq \chi_{\sigma > \alpha + 1} + \chi_{\sigma = \alpha + 1} \left(1 + \log^+ \frac{1}{x}\right) + \chi_{\sigma < \alpha + 1} x^{2\sigma - 2\alpha - 2} + x^{2\sigma - 2\alpha - 2} \exp\left(-c \frac{x}{y}\right).$$

Observe that the fourth term on the right-hand side here is controlled by the other terms, so it may be neglected. Moreover, the sum of the first three terms is separated from 0 and thus controls $U_1(x, y)$. This means that

$$K^{\alpha, \sigma}(x, y) \simeq \chi_{\sigma > \alpha + 1} + \chi_{\sigma = \alpha + 1} \left(1 + \log^+ \frac{1}{x}\right) + \chi_{\sigma < \alpha + 1} x^{2\sigma - 2\alpha - 2}.$$
3.2 Estimates of the Dunkl Potential Kernel

We first focus our attention on the Dunkl heat kernel \( G_{t}^{\alpha,D}(x, y) \). Recall that this kernel is defined by means of the auxiliary function

\[ \Phi_{\alpha}(u) = |u|^{-\alpha} \left[ I_{\alpha}(|u|) + \text{sgn}(u)I_{\alpha+1}(|u|) \right]. \]

As we saw in Section 2.3, \( \Phi_{\alpha}(u) \approx u^{-\alpha}I_{\alpha}(u) \), \( u \geq 0 \), with the value at \( u = 0 \) understood in a limiting sense. However, for \( u < 0 \) the situation is more subtle, because of the cancellation occurring in the difference of the Bessel functions. Thus we now analyze the function

\[ \Psi_{\alpha}(u) := I_{\alpha}(u) - I_{\alpha+1}(u), \quad u > 0. \]

For \( \alpha = -1/2 \) this has an explicit form (cf. [5, (5.8.5)]) and we have

\[ \Psi_{-1/2}(u) = \frac{\sqrt{2}}{\pi u} \exp(-u); \]

notice the exponential decay. Further, when \( \alpha < -1/2 \), it is not difficult to see that \( \Psi_{\alpha}(u) \) is negative for sufficiently large \( u \). Indeed, by the standard large argument asymptotics for the Bessel function (cf. [5, (5.11.10)]) we have

\[ I_{\nu}(u) = \left( \frac{2}{\pi u} \right)^{1/2} \exp(u) \left[ 1 - \frac{(\nu - 1/2)(\nu + 1/2)}{2u} + O(u^{-2}) \right] \]

for large \( u \), hence when \( \alpha \neq -1/2 \)

\[ \Psi_{\alpha}(u) \sim \frac{\alpha + 1/2}{u} I_{\alpha}(u), \quad u \to \infty; \quad (17) \]

here \( \sim \) means the asymptotic equality, i.e. that the ratio of the two quantities tends to 1 as \( u \to \infty \). Finally, in case \( \alpha > -1/2 \) we use [6, Theorem 2] (specified to \( L_{\nu,1,0} \) and \( U_{\nu,2,0} \); see [6, p. 10]) getting

\[ \frac{\alpha + 1/2}{\alpha + 1/2 + u} < 1 - \frac{I_{\alpha+1}(u)}{I_{\alpha}(u)} < \frac{2(\alpha + 1)}{2(\alpha + 1) + u}, \quad u > 0. \]

This implies

\[ \Psi_{\alpha}(u) \simeq I_{\alpha}(u) \left( 1 \wedge u^{-1} \right), \quad u > 0. \quad (18) \]

Here, in contrast with the Hermite case \( \alpha = -1/2 \), we have an exponential growth as \( u \to \infty \).

From the above considerations we draw the following conclusions. The behavior of \( G_{t}^{\alpha,D}(x, y) \) is qualitatively different in the singular case \( \alpha = -1/2 \) (trivial multiplicity function). The case \( \alpha < -1/2 \) (negative multiplicity functions) is exotic in the sense that the heat kernel takes also negative values. Indeed, taking into account Eq. 17, we have \( G_{t}^{\alpha,D}(x, y) < 0 \) when \( xy < 0 \) and \( |xy|/\sinh 2t \) is large enough. On the other hand, the case \( \alpha > -1/2 \) is more standard. With the aid of Lemma 3.3 and Eq. 1 we can describe the behavior of \( G_{t}^{\alpha,D}(x, y) \) in terms of the Hermite heat kernel \( G_{t}(x, y) = G_{t}^{-1/2,D}(x, y) \).

**Proposition 3.5** Let \( \alpha > -1/2 \). The following estimates hold uniformly in \( x, y \in \mathbb{R} \) and \( t > 0 \).

(a) If \( xy \geq 0 \), then

\[ G_{t}^{\alpha,D}(x, y) \simeq G_{t}(|x|, |y|) \begin{cases} \cosh(2t)^{-\alpha-1/2}, & xy \leq \sinh 2t, \\ (xy)^{-\alpha-1/2}, & xy > \sinh 2t. \end{cases} \]
(b) If $xy < 0$, then

$$G^{\alpha, D}_t(x, y) \simeq G_t(|x|, |y|)\begin{cases} (\sinh 2t)^{-\alpha -1/2}, & |xy| \leq \sinh 2t, \\ \sinh(2t)|xy|^{-\alpha -3/2}, & |xy| > \sinh 2t. \end{cases}$$

**Proof** Assume first that $xy > 0$. Using the same arguments as those justifying Eq. 6 we get $G^{\alpha, D}_t(x, y) \simeq G^\alpha_t (|x|, |y|)$ for $x$ and $y$ in question. Then the conclusion follows from Lemma 3.3. The case when $xy = 0$ is even simpler. Recall that $\Phi_\alpha(0)$ is a positive constant (depending on $\alpha$) and observe that the desired relation is an immediate consequence of Eq. 3. Let now $xy < 0$. By Eq. 18

$$\Phi_\alpha(u) \simeq |u|^{-\alpha} I_\alpha(|u|) \left(1 \wedge |u|^{-1}\right), \quad u < 0.$$ Combining this with Eqs. 3 and 1 we see that

$$G^{\alpha, D}_t(x, y) \simeq G^\alpha_t (|x|, |y|) \left(1 \wedge \frac{\sinh 2t}{|xy|}\right), \quad xy < 0.$$ An application of Lemma 3.3 finishes the proof. \qed

Note that item (a) in Proposition 3.5 will not be needed for the proof of Theorem 2.4, but we stated it for the sake of completeness. On the other hand, Proposition 3.5 (b) is essential, together with good estimates of the resulting auxiliary kernel

$$\tilde{K}^{\alpha, \sigma}(x, y) = \int_0^\infty \left(\frac{\sinh 2t}{xy} \wedge 1\right) (xy \vee \sinh 2t)^{-\alpha -1/2} G_t(x, y)t^{\sigma -1} dt, \quad x, y > 0.$$

**Lemma 3.6** Let $\alpha > -1$. The following estimates hold uniformly in $x, y > 0$.

(a) If $xy \leq 1$, then

$$\tilde{K}^{\alpha, \sigma}(x, y) \simeq \exp\left(-c(x+y)^2\right) + (x+y)^{2\sigma - 2} J_{d - \sigma} \left(c_1(x+y)^2, c_2 \frac{(x+y)^2}{xy}\right)$$

$$+ (xy)^{\sigma - \alpha - 1} E_{\sigma - 1/2} \left(c \frac{(x-y)^2}{xy}, cxy(x+y)^2\right),$$

where $c_1 < c_2$ are positive constants, independent of $x$ and $y$, that may be different in the lower and upper estimate.

(b) If $xy > 1$, then

$$\tilde{K}^{\alpha, \sigma}(x, y) \simeq \exp\left(-c(x+y)^2\right) + (xy)^{-\alpha - 3/2} E_{\sigma - 1/2} \left(c(x-y)^2, c(x+y)^2\right).$$

**Proof** Using the notation of the proof of Lemma 3.4 and recalling the explicit formulas for $G_t(x, y)$, we can write

$$\tilde{K}^{\alpha, \sigma}(x, y) \simeq (xy)^{-\alpha - 3/2} \int_0^{p(xy)} (\sinh 2t)^{1/2} e^{-t^{\sigma - 1}} \exp\left(-\frac{1}{4} \left[\tanh(t)(x+y)^2 + \coth(t)(x-y)^2\right]\right) dt$$

$$+ \int_p^{\infty} (\sinh 2t)^{-\alpha - 1} t^{\sigma - 1} \exp\left(-\frac{1}{2} \coth(2t) \left(x^2 + y^2\right)\right) dt$$

$$\equiv I_0 + I_\infty.$$
Here $I_\infty$ is the same as in the proof of Lemma 3.4, and from that proof we know that
\[
I_\infty \simeq \exp \left( -c(x^2 + y^2) \right) + \chi_{\{xy \leq 1\}}(x + y)^{2 \sigma - 2 \alpha - 2} J_{\alpha - \sigma} \left( c_1(x + y)^2, c_2 \frac{(x + y)^2}{xy} \right).
\]
Thus it remains to analyze $I_0$.

In case (a) we have $p(xy) \lesssim xy \leq 1$, so
\[
I_0 \simeq (xy)^{-\alpha-3/2} \int_0^{p(xy)} t^{\sigma-1/2} \exp \left( -c \left[ t^{-1}(x - y)^2 + t(x + y)^2 \right] \right) dt.
\]
The right-hand side here coincides with the right-hand side in Eq. 10 after replacing $\alpha$ by $\alpha + 1$ and $\sigma$ by $\sigma + 1$. Thus we already know that
\[
I_0 \simeq (xy)^{\alpha-1} E_{\sigma-1/2} \left( c \frac{(x - y)^2}{xy}, cxy(x + y)^2 \right).
\]
Considering (b), when $xy > 1$ we have
\[
I_0 \simeq (xy)^{-\alpha-3/2} \int_0^{p(xy)} t^{\sigma-1/2} \exp \left( -c \left[ t^{-1}(x - y)^2 + t(x + y)^2 \right] \right) dt
\]
\[
+ (xy)^{-\alpha-3/2} \exp \left( -c(x^2 + y^2) \right) \int_{p(1)}^{\infty} t^{\sigma-1} e^t dt
\]
\[
\equiv I_{0,1} + I_{0,2}.
\]
As in the proof of Lemma 3.4,
\[
I_{0,1} \simeq (xy)^{-\alpha-3/2} E_{\sigma-1/2} \left( c(x - y)^2, c(x + y)^2 \right).
\]
Moreover, since $e^{2p(xy)} \simeq xy$,
\[
I_{0,2} \lesssim (xy)^{-\alpha-3/2} \exp \left( -c(x^2 + y^2) \right) \int_{p(1)}^{p(xy)} e^t dt
\]
\[
\lesssim (xy)^{-\alpha-1/2} \exp \left( -c(x^2 + y^2) \right) \simeq \exp \left( -c(x + y)^2 \right).
\]
The conclusion follows.

Proof of Theorem 2.4 Let us first assume $xy \geq 0$. Observe that $K^{\alpha,\sigma}_D(x, y) = K^{\alpha,\sigma}_D(-x, -y)$, so it is enough to consider the case $x, y \geq 0$. If $x, y > 0$, then we easily get the desired estimates by means of Eq. 8 and Theorem 2.1. If $x = 0$ or $y = 0$, then Eq. 8 still holds, with a limiting understanding of the values of $K^{\alpha,\sigma}(x, y)$ and, implicitly, $G^\alpha_t(x, y)$. Tracing the proof of Theorem 2.1, one can ensure that the asserted bounds for $K^{\alpha,\sigma}(x, y)$ remain true for all $x, y \geq 0$, hence the conclusion again follows.

Assume next that $xy < 0$. Taking into account Proposition 3.5 (b), we infer that $K^{\alpha,\sigma}_D(x, y) \simeq \tilde{K}^{\alpha,\sigma}([x], [y])$. On the other hand, the estimates of Lemma 3.6 coincide with the estimates of Lemma 3.4 with $\alpha$ replaced by $\alpha + 1$ and $\sigma$ replaced by $\sigma + 1$. Thus the behavior of $\tilde{K}^{\alpha,\sigma}(x, y)$ is the same as the behavior of $K^{\alpha+1,\sigma+1}(x, y)$ in the sense of the bounds from Theorem 2.1. Now the conclusion follows by observing that $|x| + |y| = |x - y|$ and $|x| - |y| = |x + y|$ when $xy < 0$.

Finally, we prove Proposition 2.5.

Proof of Proposition 2.5 Let $x, y \in \mathbb{R}^2$ be such that $xy < 0$. By the asymptotics Eq. 17 it follows that
\[
G^\alpha_{t,D}(x, y) \lesssim -G_1([x], [y]) \sinh(2t)|xy|^{-\alpha-3/2} \tag{19}
\]
provided that $|xy|/\sinh 2t$ is sufficiently large. We then focus on $x$ and $y$ such that Eq. 19 holds uniformly in $t \leq p(1)$, and we may assume that $|xy| > 1$. As in the proof of Lemma 3.6 (b), we infer that

$$K_D^{\alpha,\sigma}(x, y) \leq c_1 \exp\left(-c_2(|x| + |y|)^2\right) - c_3|x||y|^{-a - 3/2} E_{\sigma - 1/2}(c_4(|x| - |y|)^2, c_4(|x| + |y|)^2)$$

for $x, y$ in question, with some positive constants $c_i, i = 1, \ldots, 4$. The right-hand side here is certainly negative when $y = -x$ and $|x|$ is large enough, say $|x| \geq C > 0$, as can be seen from Lemma 3.2. For continuity reasons, the same must be true for $(x, y)$ lying in a neighborhood of the set $\{(x, y) : x = -y, |x| \geq C\}$. 

\section{4 $L^p - L^q$ Estimates}

This section is devoted to the proofs of Theorems 2.2, 2.3 and 2.6. Given $1 \leq p \leq \infty$, we denote by $p'$ its conjugate exponent, $1/p + 1/p' = 1$.

\subsection{4.1 $L^p - L^q$ Estimates in the Laguerre Setting of Convolution Type}

Theorem 2.2 follows immediately from the two lemmas below that describe sharply $L^p - L^q$ behavior of two auxiliary operators (with non-negative kernels) into which $I^{\alpha,\sigma}$ splits naturally. These operators are interesting in their own right, so for the sake of completeness the lemmas provide slightly more information than actually needed to conclude Theorem 2.2.

We split $I^{\alpha,\sigma}$ according to the kernel splitting

$$K^{\alpha,\sigma}(x, y) = \chi_{\{|x| \leq 2, |y| \leq 2\}} K^{\alpha,\sigma}(x, y) + \chi_{\{|x| \lor |y| > 2\}} K^{\alpha,\sigma}(x, y) \equiv K_0^{\alpha,\sigma}(x, y) + K_{\infty}^{\alpha,\sigma}(x, y)$$

and denote the resulting integral operators by $I_0^{\alpha,\sigma}$ and $I_{\infty}^{\alpha,\sigma}$, respectively.

\begin{lemma}
Let $\alpha > -1$, $\sigma > 0$ and $1 \leq p, q \leq \infty$. Set $\delta := ((-1/2) \lor \alpha) + 1$. Then $I_0^{\alpha,\sigma}$ is bounded from $L^p(d\mu_{\alpha})$ to $L^q(d\mu_{\alpha})$ if and only if

$$\frac{1}{p} - \frac{\sigma}{\delta} \leq \frac{1}{q}$$

and $(\frac{\sigma}{\delta}, 0) \neq (\frac{1}{p}, \frac{1}{q}) \neq (1, 1 - \frac{\sigma}{\delta})$.
\end{lemma}

\begin{lemma}
Let $\alpha > -1$, $\sigma > 0$ and $1 \leq p, q \leq \infty$. Set $\eta := 1/2 \lor (-\alpha)$. Then $I_{\infty}^{\alpha,\sigma}$ is bounded from $L^p(d\mu_{\alpha})$ to $L^q(d\mu_{\alpha})$ if and only if

$$\frac{1}{p} - \frac{\sigma}{\eta} \leq \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha + 1}$$

and $(2\sigma, 0) \neq (\frac{1}{p}, \frac{1}{q}) \neq (1, 1 - 2\sigma)$ when $\sigma \leq \eta = 1/2$.
\end{lemma}

The first of these lemmas follows essentially from the recent results of Nowak and Roncal [7] for potential operators in the setting of Jacobi expansions.

\begin{proof}[Proof of Lemma 4.1]
In view of Theorem 2.1, $K_0^{\alpha,\sigma}(x, y)$ satisfies the sharp estimates of Theorem 2.1 (i) in the square $0 < x, y < 2$, and vanishes outside this square. Comparing to [7, Theorem 2.2], we see that the behavior of $K_0^{\alpha,\sigma}(x, y)$ for $x, y \leq 2$ is exactly the...
A. Nowak, K. Stempak

same as the behavior of the Jacobi potential kernel $K^{\alpha,\beta}_\sigma(\theta, \varphi)$ in the Jacobi trigonometric polynomial setting on the interval $(0, \pi)$. More precisely, for any fixed $\beta > -1$,

$$K^{\alpha,\sigma}_0(x, y) \simeq K^{\alpha,\beta}_\sigma(x, y), \quad 0 < x, y \leq 2.$$ 

Moreover, the Laguerre and Jacobi measures are comparable on the interval $(0, 2]$.

It is now clear that the positive results of [7, Theorem 2.3] for the Jacobi potential operator are inherited by $I^{\alpha,\sigma}_0$. Choosing $\beta \leq -\frac{1}{2}$ we conclude the mapping properties of $I^{\alpha,\sigma}_0$ asserted in the lemma. If in addition $\beta \leq \alpha$, all the counterexamples and related arguments given in the proof of [7, Theorem 2.3], see [7, Section 4.1], remain valid for $I^{\alpha,\sigma}_0$. Hence in this case $I^{\alpha,\sigma}_0$ inherits also the negative results stated in [7, Theorem 2.3]. This completes the proof.

To prove Lemma 4.2 we will need the technical result stated below.

**Lemma 4.3** Let $\alpha > -1$ and $\sigma > 0$. Then the estimates

$$\|K^{\alpha,\sigma}_\infty(x, \cdot)\|_{L^p(d\mu_\alpha)} \simeq (1 \vee x)^{-2\sigma+2\alpha(1/p-1)}, \quad x > 0, \quad (20)$$

hold for $1 \leq p \leq \infty$ when $\sigma > 1/2$ and for $1 \leq p < \frac{1}{1-2\sigma}$ when $\sigma \leq 1/2$.

Moreover, for $\sigma \leq 1/2$ and $\frac{1}{1-2\sigma} \leq p \leq \infty$, we have

$$\|K^{\alpha,\sigma}_\infty(x, \cdot)\|_{L^p(d\mu_\alpha)} = \infty, \quad x > 4. \quad (21)$$

Actually, only Eq. 20 will be used in the sequel. However, we include also Eq. 21 to show that Eq. 20 is optimal in the sense of the range of admissible parameters.

**Proof of Lemma 4.3** By Theorem 2.1, $K^{\alpha,\sigma}_\infty(x, y)$ satisfies the estimates of Theorem 2.1 (ii) outside the square $0 < x, y \leq 2$, and vanishes inside this square. Therefore, it is convenient to consider separately the cases $\sigma < 1/2$, $\sigma = 1/2$ and $\sigma > 1/2$. In what follows we treat the case $\sigma < 1/2$ leaving a similar analysis for the remaining cases to the reader. We only mention that in the case $\sigma = 1/2$ it is convenient to split further the kernel according to the summands in the factor $1 + \log^+ \frac{1}{|x-y|(x+y)}$. Then the part related to the 1 can be included into the discussion of the case $\sigma < 1/2$ to give Eq. 20, while the part coming from the $\log^+$ does not make worse the upper bound in Eq. 20 and is decisive for Eq. 21. Finally, we observe that considering $0 < x < 1$ and $x > 4$ is enough for the proof of Eq. 20 since for $1 \leq p < \infty$ each of the two functions

$$x \mapsto \int_0^\infty f^{\sigma,\alpha}(x, y)^p y^{2\sigma+1} dy, \quad a = 0, 2,$$

where $f^{\sigma,\alpha}(x, y)$ denotes the expression on the right-hand side of "\(\simeq\)" in Theorem 2.1 (ii), is continuous on $(0, \infty)$; as for $p = \infty$, the same is true for $x \mapsto \sup_{y \geq a} f^{\sigma,\alpha}(x, y), a = 0, 2$, provided that $\sigma > 1/2$. This may be checked in detail with the aid of the dominated convergence theorem when $p < \infty$, or directly otherwise.

Let $\sigma < 1/2$. In view of Theorem 2.1 (ii),

$$K^{\alpha,\sigma}_\infty(x, y) \simeq \chi_{\{x+y>2\}}(x+y)^{-2\alpha-1}x - y)^{2\sigma-1} \exp(-c|x-y|(x+y)).$$

Therefore, if $0 < x < 1$, then

$$\int_2^\infty K^{\alpha,\sigma}_\infty(x, y)^p y^{2\sigma+1} dy \simeq \int_2^\infty y^{(2\sigma+1)(1-p)+(2\sigma-1)p} \exp(-c p y^2) dy \simeq 1$$

\copyright Springer
for $p < \infty$, and
\[
\sup_{y > 2} K^{\alpha,\sigma}_\infty (x, y) \lesssim \sup_{y > 2} y^{2\sigma - 2\alpha - 2} \exp(-cy^2) \lesssim 1.
\]

Thus Eq. 20 for $x < 1$ follows. If $x > 4$, then for $p < \frac{1}{1 - 2\sigma}$ and for the decisive interval $(x/2, 3x/2)$ we have
\[
\int_{x/2}^{3x/2} K^{\alpha,\sigma}_\infty (x, y)^p y^{2\alpha + 1} dy \lesssim x^{(2\alpha + 1)(1 - p)} \int_{x/2}^{3x/2} \exp(-cpx|y - y|)|y - y|^{(2\sigma - 1)p} dy
\]
\[
= 2x^{-2\sigma p + 2\alpha(1 - p)} \int_0^{3x/2} \exp(-cpu|y - y|)|y - y|^{2\sigma - 1} dy
\]
\[
\lesssim x^{-2\sigma p + 2\alpha(1 - p)}.
\]

Notice that the assumption imposed on $p$ guarantees convergence of the last integral. Checking that the relevant integrals over $(0, x/2)$ and $(3x/2, \infty)$ are controlled by $x^{-2\sigma p + 2\alpha(1 - p)}$ is straightforward. Now Eq. 20 follows.

If $\frac{1}{1 - 2\sigma} \leq p < \infty$, then the above argument leads also to Eq. 21. Finally, we have
\[
\|K^{\alpha,\sigma}_\infty (x, \cdot)\|_\infty \geq \text{ess sup}_{x/2 < y < 3x/2} K^{\alpha,\sigma}_\infty (x, y)
\]
\[
\lesssim x^{-2\sigma - 1} \text{ess sup}_{x/2 < y < 3x/2} \exp(-cx|y - y|)|y - y|^{2\sigma - 1} = \infty
\]
which justifies Eq. 21 for $p = \infty$. \hfill \Box

Proof of Lemma 4.2 The structure of the proof is as follows. The upper estimate of Lemma 4.3 readily enables us to establish $L^p - L^1$ and $L^1 - L^q$ boundedness of $I^{\alpha,\sigma}_\infty$ for the admissible $p$ and $q$. This, together with a duality argument based on the symmetry of the kernel, $K^{\alpha,\sigma}_\infty (x, y) = K^{\alpha,\sigma}_\infty (y, x)$, and the Riesz-Thorin interpolation theorem, gives $L^p - L^q$ bounds for $p$ and $q$ satisfying
\[
\frac{1}{p} - \frac{\sigma}{\eta} < 1 < \frac{1}{q} - \frac{\sigma}{\alpha + 1},
\]
where the first inequality should be replaced by a weak one in case $\eta > 1/2$. The case when $\sigma < \eta = 1/2$ and $\frac{1}{p} - \frac{\sigma}{\eta} = \frac{1}{q} - 2\sigma < \frac{1}{p} < 1$, is more subtle and will be treated by different methods. Finally, the lack of $L^p - L^q$ boundedness for the relevant $p$ and $q$ will be shown by giving explicit counterexamples. To simplify the notation, in what follows $\| \cdot \|_p$ denotes the norm in the Lebesgue space $L^p(\mathbb{R}_+, d\mu_\alpha)$.

The $L^p - L^1$ boundedness of $I^{\alpha,\sigma}_\infty$ holds for
\[
p \in \left\{ \begin{array}{ll}
(1, \infty], & \sigma > \alpha + 1, \\
\left[ 1, \frac{\alpha + 1}{\sigma + 1 - \sigma} \right), & \sigma \leq \alpha + 1.
\end{array} \right.
\]

Indeed, by Hölder’s inequality we have
\[
\|I^{\alpha,\sigma}_\infty f\|_1 \leq \|f\|_p \|K^{\alpha,\sigma}_\infty (\cdot, y)\|_1\|_{p'}
\]
(here and elsewhere we use the convention that the outer norms are taken with respect to the $y$ variable) and the assertion follows provided that $\|K^{\alpha,\sigma}_\infty (\cdot, y)\|_1\|_{p'} < \infty$. If $p = 1$ this is the case for any $\sigma > 0$ since
\[
\|K^{\alpha,\sigma}_\infty (\cdot, y)\|_\infty = \text{ess sup}_{y > 0} \|K^{\alpha,\sigma}_\infty (\cdot, y)\|_1 \lesssim \sup_{y > 0} (1 + y)^{-2\sigma} < \infty.
\]
Similarly, for $1 < p \leq \infty$,  
\[
\|K_{\infty}^{\alpha, \sigma}(\cdot, y)\|_1^{p^*} \lesssim \int_0^\infty (1 + y)^{-2\sigma p' + 2\alpha + 1} dy < \infty,
\]
provided that $-2\sigma p' + 2\alpha + 1 < -1$, and this happens if $p$ satisfies the imposed restrictions.

The $L^1 - L^q$ boundedness of $I_{\infty}^{\alpha, \sigma}$ holds for  
\[
q \in \begin{cases} [1, \infty], & \sigma > 1/2, \\ \left[1, \frac{1}{1 - \alpha} \right], & \sigma \leq 1/2, \end{cases}
\]
or  
\[
q \in \begin{cases} [1, \infty], & \sigma \geq -\alpha, \\ \left[\frac{1}{\alpha + \sigma}, \infty\right], & \sigma < -\alpha, \end{cases}
\]
when $\alpha \geq -1/2$ or $-1 < \alpha < -1/2$, respectively. Indeed, by Minkowski’s integral inequality (naturally extended to the case $q = \infty$), we get  
\[
\|I_{\infty}^{\alpha, \sigma} f\|_q \leq \|f\|_1 \|K_{\infty}^{\alpha, \sigma}(\cdot, y)\|_q \|_{L^q} \|_{L^q}
\]
and the assertion follows provided that $\|K_{\infty}^{\alpha, \sigma}(\cdot, y)\|_q \|_{L^q} \|_{L^q} < \infty$. For $q = \infty$ this is the case if either $\alpha \geq -1/2$ and $\sigma > 1/2$, or $-1 < \alpha < -1/2$ and $\sigma \geq -\alpha$, since then  
\[
\|K_{\infty}^{\alpha, \sigma}(\cdot, y)\|_{L^q} \|_{L^q} \|_{L^q} \leq \sup_{y > 0} (1 + y)^{-2(\sigma + \alpha)} < \infty.
\]
On the other hand, for $1 < q < \infty$ in case $\sigma > 1/2$, or for $1 \leq q \leq \frac{1}{1 - 2\alpha}$ in case $\sigma \leq 1/2$ (so that Lemma 4.3 can be applied),  
\[
\|K_{\infty}^{\alpha, \sigma}(\cdot, y)\|_q \|_{L^q} \|_{L^q} \leq \sup_{y > 0} (1 + y)^{-2\alpha + 2(1/q - 1)} < \infty,
\]
provided that $\alpha (\frac{1}{2} - 1) \leq \sigma$, and this happens if $q$ satisfies the imposed restrictions.

We now use the fact that, due to the symmetry of the kernel and a duality argument, $L^p - L^q$ boundedness of $I_{\infty}^{\alpha, \sigma}$ for some $1 \leq p, q < \infty$ implies $L^q - L^p$ boundedness of $I_{\infty}^{\alpha, \sigma}$. This allows us to infer from the results already obtained that $I_{\infty}^{\alpha, \sigma}$ is $L^\infty - L^q$ bounded provided that  
\[
q \in \begin{cases} (1, \infty], & \sigma > \alpha + 1, \\ \left(\frac{\alpha + 1}{\alpha}, \infty\right], & \sigma \leq \alpha + 1, \end{cases}
\]
and $L^p - L^\infty$ bounded provided that  
\[
p \in \begin{cases} (1, \infty], & \sigma > 1/2, \\ \left(\frac{1}{2\sigma}, \infty\right], & \sigma \leq 1/2, \end{cases}
\]
or  
\[
p \in \begin{cases} (1, \infty], & \sigma \geq -\alpha, \\ \left[-\frac{\sigma}{\alpha}, \infty\right], & \sigma < -\alpha, \end{cases}
\]
when $\alpha \geq -1/2$ or $-1 < \alpha < -1/2$, respectively.

Starting from the four $L^p - L^q$ estimates obtained above, we apply the Riesz-Thorin interpolation theorem (see Fig. 1) to conclude $L^p - L^q$ boundedness of $I_{\infty}^{\alpha, \sigma}$ in all the relevant cases, except for the one when  
\[
\sigma < \eta = \frac{1}{2} \quad \text{and} \quad \frac{1}{p} - \frac{\sigma}{\eta} = \frac{1}{q} \quad \text{and} \quad 2\alpha < \frac{1}{p},
\]
(22)

To finish proving the positive results of the lemma, we consider $\sigma, \alpha, p$ and $q$ satisfying Eq. 22; in particular, now $\alpha \geq -1/2$. We claim that $I_{\infty}^{\alpha, \sigma}$ is $L^p - L^q$ bounded. Observe that  
\[
K_{\infty}^{\alpha, \sigma}(x, y) \lesssim \chi_{\{x, y \leq 1\}} y^{2\sigma - 2(\alpha + 1)} + \chi_{\{x, y > 1\}} x^{2\sigma - 2(\alpha + 1)} + \chi_{\{x, y > 1\}} (x + y)^{-2\alpha - 1} |x - y|^{2\sigma - 1}.
\]

By means of Hölder’s inequality, it is straightforward to check that the first two terms here define $L^p - L^q$ bounded integral operators. Thus our task reduces to showing that the integral operator  
\[
U^{\alpha, \sigma} f(x) = \int_1^\infty (x + y)^{-2\alpha - 1} |x - y|^{2\sigma - 1} f(y) \, d\mu_\alpha(y), \quad x > 1,
\]
satisfies the desired mapping property with respect to the measure space \(((1, \infty), d\mu_\alpha)\). Since \(\mu_\alpha(B(x, r)) \approx r(x + r)^{2\alpha+1}, r > 0, x > 1\) (see [8, Proposition 3.2]; here the balls \(B(x, r)\) are understood in the sense of the space of homogeneous type \(((1, \infty), |\cdot|, d\mu_\alpha)\), we have
\[
I_{x, \sigma} \approx \int_1^\infty \frac{|x - y|^{2\sigma}}{\mu_\alpha(B(x, |x - y|))} f(y) d\mu_\alpha(y), \quad x > 1.
\] (23)
Integral operators of this form were investigated in [2], among others. In particular, taking into account that the estimate \(\mu_\alpha(B(x, r)) \approx r^{2\alpha+1}\) holds uniformly in \(r > 0\) and \(x > 1\), we can apply \([2, \text{Corollary 5.2}]\) (specified to \(n = 1\) and \(w = 1\)) to the operator defined by the right-hand side in Eq. 23. This gives the desired conclusion for \(U_{x, \sigma}^{\alpha, \sigma}\).

Passing to the negative results, we must prove the following three items.

(a) \(I_{x, \sigma}^{\alpha, \sigma}\) is not \(L^p - L^q\) bounded when \(\frac{1}{p} + \frac{\sigma}{\alpha + 1} \leq \frac{1}{q}\) and \(\sigma \leq \alpha + 1\).

(b) \(I_{x, \sigma}^{\alpha, \sigma}\) is not \(L^p - L^q\) bounded when \(\frac{1}{q} < \frac{1}{p} - \frac{\sigma}{\alpha + 1}\) and \(\sigma < \eta\).

(c) \(I_{x, \sigma}^{\alpha, \sigma}\) is not \(L^p - L^q\) bounded for \((\frac{1}{p}, \frac{1}{q}) = (2\sigma, 0)\) and \((\frac{1}{p}, \frac{1}{q}) = (1, 1 - 2\sigma)\) when \(\sigma \leq \eta = 1/2\).

To show (a), consider first \(p = \infty\). If \(\frac{\sigma}{\alpha + 1} \leq \frac{1}{q}\) then, by Lemma 4.3,
\[
\|I_{x, \sigma}^{\alpha, \sigma}\|_q^q \approx \int_0^\infty (1 + x)^{-2\sigma q} x^{2\alpha+1} dx = \infty,
\]
hence \(I_{x, \sigma}^{\alpha, \sigma}\) is not \(L^\infty - L^q\) bounded. To treat the case \(p < \infty\), we may assume in addition that \(\frac{1}{q} = \frac{1}{p} + \frac{\sigma}{\alpha + 1}\), because of an interpolation argument. Let \(f(y) = \chi_{\{y > e\}} y^{-(2\alpha + 1)/p} (\log y)^{1/p - \sigma/(\alpha + 1)}\). Then
\[
\|f\|_p^p = \int_e^\infty (\log y)^{-1/2 - \sigma p/\alpha + 1} dy < \infty,
\]
so \(f \in L^p(d\mu_\alpha)\). We claim that \(I_{x, \sigma}^{\alpha, \sigma} f \notin L^q(d\mu_\alpha)\). Indeed, using the lower bound from Theorem 2.1 (ii), for \(x > 2e\) we obtain
\[
I_{x, \sigma}^{\alpha, \sigma} f(x) \approx f(x) \int_{x - 1/x}^x K_{x, \sigma}^{\alpha, \sigma}(x, y) d\mu_\alpha(y) \gtrsim f(x) \int_{x - 1/x}^x \left\{ \begin{array}{ll} (x - y)^{2\sigma - 1}, & \sigma < 1/2 \\ 1 + \log^+ \frac{1}{x(y - x)}, & \sigma = 1/2 \\ x^{1 - 2\sigma}, & \sigma > 1/2 \end{array} \right\} dy
\]
\[
\approx x^{-2\sigma} f(x),
\]
where the last relation in case \(\sigma = 1/2\) follows by the change of variable \(y = x - u/x\).

Consequently,
\[
I_{x, \sigma}^{\alpha, \sigma} f(x) \gtrsim x^{-2(\alpha + 1)/p - 2\sigma} (\log x)^{-1/p - \sigma/(\alpha + 1)} = x^{-2(\alpha + 1)/q} (\log x)^{-1/q}, \quad x > 2e,
\]
and the claim follows.

To justify (b), we fix \(p\) and \(q\) satisfying the assumed conditions and first consider the case \(\alpha \geq -1/2\). This means that \(\eta = 1/2\) and \(\sigma < 1/2\). Then, by Theorem 2.1 (ii),
\[
K_{x, \sigma}^{\alpha, \sigma}(x, y) \gtrsim |x - y|^{2\sigma - 1}, \quad x, y \in (2, 4).
\] (24)
Let \(f(y) = \chi_{(2, 3)}(y)(3 - y)^A\), where we take \(A = -\frac{1}{p} + \epsilon\), with \(\epsilon\) satisfying \(0 < \epsilon < \frac{1}{p} - 2\sigma - \frac{1}{q}\). Clearly, \(f \in L^p(d\mu_\alpha)\) since
\[
\|f\|_p^p \approx \int_2^3 (3 - y)^{-1/2 + \epsilon} dy < \infty.
\]
We will show that \( I_{\alpha}^{\sigma, \sigma} f \notin L^q(d\mu_\alpha) \). Changing the variable of integration, we get
\[
I_{\alpha}^{\sigma, \sigma} f(x) \gtrsim \int_2^3 (x-y)^{2\sigma-1}(3-y)^A \, dy = (x-3)^{2\sigma+A} \int_0^{1/(x-3)} \frac{u^A \, du}{(1+u)^{2\sigma}}, \quad x \in (3, 4).
\]
Here \( 1/(x-3) > 1 \), so the last integral is larger than a positive constant. Thus
\[
I_{\alpha}^{\sigma, \sigma} f(x) \gtrsim (x-3)^{2\sigma+A}, \quad x \in (3, 4).
\]
Since \( 2\sigma + A < 0 \), we see that \( I_{\alpha}^{\sigma, \sigma} f \) is not in \( L^\infty \). Neither it belongs to \( L^q(d\mu_\alpha) \) when \( q < \infty \), because \( (2\sigma+A)q < -1 \) and, consequently,
\[
\| I_{\alpha}^{\sigma, \sigma} f \|_q^q \gtrsim \int_3^4 (x-3)^{(2\sigma+A)q} \, dx = \infty.
\]
The case \( \alpha < -1/2 \) is slightly more subtle. Now \( \eta = -\alpha \) and we must show that \( I_{\alpha}^{\sigma, \sigma} \) is not \( L^p - L^q \) bounded whenever \( \frac{1}{q} < \frac{1}{p} + \frac{\sigma}{\alpha} \). Let \( n \) be large. Observe that in view of Theorem 2.1 (ii), for \( x, y \in (n, n+1/n) \) we have
\[
K_{\alpha, \sigma}^{\alpha, \sigma}(x, y) \gtrsim n^{-2\alpha-1} \begin{cases} |x-y|^{2\alpha-1}, & \sigma < 1/2, \\ \log \frac{2}{n|x-y|}, & \sigma = 1/2, \\ n^{-2\alpha+1}, & \sigma > 1/2, \end{cases}
\]
uniformly in \( x, y \) and \( n \). Take \( f_n = \chi_{(n, n+1/n)} \) and assume that \( x \in (n, n+1/n) \). Then
\[
I_{\alpha}^{\sigma, \sigma} f_n(x) \gtrsim \int_n^{n+1/n} \begin{cases} (y-n)^{2\alpha-1}, & \sigma < 1/2, \\ \log \frac{2}{n(y-n)}, & \sigma = 1/2, \\ n^{-2\alpha+1}, & \sigma > 1/2, \end{cases} \, dy \asymp n^{-2\alpha}.
\]
Consequently,
\[
\| I_{\alpha}^{\sigma, \sigma} f_n \|_q \gtrsim \int_n^{n+1/n} n^{-2\sigma q} n^{2\alpha+1} \, dy \asymp n^{-2\sigma q+2\alpha}.
\]
Taking into account that \( \| f_n \|_p \asymp n^{2\alpha/p} \) we get, with \( q = \infty \) also admitted,
\[
\frac{\| I_{\alpha}^{\sigma, \sigma} f_n \|_q}{\| f_n \|_p} \asymp n^{-2\sigma q+2\alpha(1/p-1/q)}.
\]
Since \( -2\sigma - 2\alpha(\frac{1}{p} - \frac{1}{q}) > 0 \), the norm ratio is not bounded as \( n \to \infty \).

Proving (c), we begin with the extreme case \( \sigma = 1/2 \) and show that \( I_{\alpha}^{\sigma, \sigma} \) is not \( L^1 - L^\infty \) bounded. Let \( f_n = \chi_{(3-1/n, 3)} \) with \( n \) large. Then \( \| f_n \|_1 \asymp n^{-1} \) and by Theorem 2.1 (ii)
\[
\| I_{\alpha}^{\sigma, \sigma} f_n \|_\infty \gtrsim \text{ess sup}_{3 < x < 3+1/n} \int_3^{3-1/n} \log \frac{1}{x-y} \, dy \asymp \int_3^{3-1/n} \log \frac{1}{3-y} \, dy \asymp \frac{1}{n} \log n,
\]
and the conclusion follows by letting \( n \to \infty \).

Next assume that \( \sigma < \eta = 1/2 \). By duality, it is enough to check that \( I_{\alpha}^{\sigma, \sigma} \) is not bounded from \( L^{1/(2\sigma)}(d\mu_\alpha) \) to \( L^\infty \). Observe that in this situation Eq. 24 holds. Take \( f(y) = \chi_{(2,3)}(y)/(3-y)^{2\sigma} \log \frac{2}{3-y} \). Then \( f \in L^{1/(2\sigma)}(d\mu_\alpha) \), but
\[
\| I_{\alpha}^{\sigma, \sigma} f \|_\infty \gtrsim \text{ess sup}_{3 < x < 4} \int_2^3 |x-y|^{2\sigma-1} \, dy = \int_2^3 \frac{1}{3-y} \, dy = \infty.
\]
This finishes the verification of item (c).

The proof of Lemma 4.2 is complete. \( \square \)
4.2 $L^p - L^q$ Estimates in the Laguerre Setting of Hermite Type

Similarly to Theorem 2.2, Theorem 2.3 follows readily from the two lemmas below describing $L^p - L^q$ behavior of two auxiliary operators with non-negative kernels which $I^\alpha,\sigma_H$ splits into. More precisely, we split the operator $I^\alpha,\sigma_H$ according to the kernel splitting

$$K^\alpha,\sigma_H(x, y) = \chi_{\{x \leq 2, y \leq 2\}}K^\alpha,\sigma_H(x, y) + \chi_{\{x \lor y > 2\}}K^\alpha,\sigma_H(x, y) \equiv K^\alpha,\sigma_H,0(x, y) + K^\alpha,\sigma_H,\infty(x, y)$$

and denote the resulting integral operators by $I^\alpha,\sigma_H,0$ and $I^\alpha,\sigma_H,\infty$, respectively.

**Lemma 4.4** Let $\alpha > -1$, $\sigma > 0$ and $1 \leq p, q \leq \infty$.

(a) If $\alpha \geq -1/2$, then $I^\alpha,\sigma_H,0$ is bounded from $L^p(dx)$ to $L^q(dx)$ if and only if

$$\frac{1}{p} - 2\sigma \leq \frac{1}{q} \quad \text{and} \quad \left( \frac{1}{p}, \frac{1}{q} \right) \notin \left\{ (2\sigma, 0), (1, 1 - 2\sigma) \right\}.$$

(b) Let $\alpha < -1/2$. Then $L^p(dx) \subset \text{Dom} I^\alpha,\sigma_H,0$ if and only if $p > 2/(2\alpha + 3)$. In this case $I^\alpha,\sigma_H,0$ is bounded from $L^p(dx)$ to $L^q(dx)$ if and only if

$$\frac{1}{p} - 2\sigma \leq \frac{1}{q} \quad \text{and} \quad \frac{1}{q} > -\alpha - \frac{1}{2}.$$

**Lemma 4.5** Let $\alpha > -1$, $\sigma > 0$ and $1 \leq p, q \leq \infty$. Then $I^\alpha,\sigma_H,\infty$ satisfies the positive $L^p - L^q$ mapping properties stated in Theorem 2.3 for $I^\alpha,\sigma_H,0$.

On the other hand, $I^\alpha,\sigma_H,\infty$ is not bounded from $L^p(dx)$ to $L^q(dx)$ when

$$\frac{1}{q} \geq \frac{1}{p} + 2\sigma.$$

The proof of Lemma 4.4 uses the sharp description of $L^p - L^q$ boundedness for the potential operator in the Jacobi trigonometric ‘function’ setting stated in [7, Theorem 2.4] and arguments analogous to those from the proof of Lemma 4.1; the first part of Lemma 4.4 (b) may be verified directly. We omit the details. To prove Lemma 4.5 we will mostly appeal to the results obtained in the setting of Laguerre expansions of convolution type. Essentially, only the case $\alpha < -1/2$ requires new arguments. However, we first give an analogue of Lemma 4.3. Although we will use only a part of it, we provide a full statement for the sake of completeness and, perhaps, the reader’s curiosity.

**Lemma 4.6** Let $\alpha > -1$, $\sigma > 0$ and $1 \leq p \leq \infty$. Then the estimates

$$\| K^\alpha,\sigma_H,\infty(x, \cdot) \|_p \simeq \begin{cases} x^{\alpha+1/2}, & x \leq 1, \\ x^{-2\sigma + 1 - 1/p}, & x > 1, \end{cases}$$

hold provided that $p$ satisfies $\frac{1}{p} > 1 - 2\sigma$ and, in addition, $\frac{1}{p} > -\alpha - 1/2$ in case $\alpha < -1/2$.

Moreover, for the remaining $p$ we have

$$\| K^\alpha,\sigma_H,\infty(x, \cdot) \|_p = \infty, \quad x > 4.$$  \hfill (25)

**Proof** The reasoning relies on the arguments from the proof of Lemma 4.3. We leave details to the reader. \( \square \)
Proof of Lemma 4.5 In view of Eq. 2 and Theorem 4.3 (ii), for $\alpha \geq -1/2$ the kernel $K_{H,\infty}^{\alpha,\sigma}(x,y)$ is controlled by $K_{\infty}^{-1/2,\sigma}(x,y)$. Thus $I_{H,\infty}^{\alpha,\sigma}$ inherits the $L^p - L^q$ boundedness of $I_{\infty}^{-1/2,\sigma}$ (note that $d\mu_{-1/2}$ is the Lebesgue measure). This together with Lemma 4.2 gives the positive results of the lemma in case $\alpha \geq -1/2$.

Next observe that for any $\alpha > -1$, the two above mentioned kernels are comparable in the sense of $\simeq$ if the arguments are comparable in the sense of $\simeq$, see Theorem 2.1 (ii),

$$K_{H,\infty}^{\alpha,\sigma}(x,y) \simeq K_{\infty}^{-1/2,\sigma}(x,y), \quad x/2 < y < 2x;$$ (26)

here the exponential factors involved are of the form $\exp(-c|x-y|(x+y))$. So to prove the required negative result in case $p < \infty$ we can use the counterexample from (a) of the proof of Lemma 4.2, since it involves only comparable arguments of the kernel. In case $p = \infty$ the conclusion follows by Lemma 4.6, since we can write

$$\|I_{H,\infty}^{\alpha,\sigma}\|_q^q \gtrsim \int_1^{\infty} x^{-2\sigma q} \, dx = \infty$$

provided that $\frac{1}{q} \geq 2\sigma$.

It remains to justify the $L^p - L^q$ boundedness in case $\alpha < -1/2$. Because of Eq. 26 and Lemma 4.2 (or rather its proof that depends on $I_{\infty}^{\alpha,\sigma}$ only through qualitatively sharp estimates of the kernel $K_{\infty}^{\alpha,\sigma}(x,y)$), it is enough to study the mutually dual integral operators

$$U_1^{\alpha,\sigma} f(x) = \int_0^{x/2} K_{H,\infty}^{\alpha,\sigma}(x,y) f(y) \, dy,$$

$$U_2^{\alpha,\sigma} f(x) = \int_{2x}^{\infty} K_{H,\infty}^{\alpha,\sigma}(x,y) f(y) \, dy.$$

Assuming that $p > 1$ and $q < \infty$, we will show that $U_1^{\alpha,\sigma}$ and $U_2^{\alpha,\sigma}$ are $L^p - L^q$ bounded when

$$\frac{1}{p'} > -\alpha - 1/2 \quad \text{and} \quad \frac{1}{q'} > -\alpha - 1/2 \quad \text{and} \quad \frac{1}{q} \geq \frac{1}{p} - 2\sigma.$$

This will finish the proof.

By Eq. 2, Theorem 2.1 (ii) and Hölder’s inequality,

$$|U_1^{\alpha,\sigma} f(x)| \lesssim x^{-\alpha - 1/2} \exp(-cx^2) \left\{ \begin{array}{ll}
  x^{2\sigma - 1}, & \sigma < 1/2 \\
  1 + \log^+ \frac{1}{x}, & \sigma = 1/2 \\
  (1 + x)^{1-2\sigma}, & \sigma > 1/2
\end{array} \right\} \|f\|_{L_{[y<x]}^{\alpha+1/2}} \|f\|_p.$$

If $(\alpha + 1/2)p' > -1$, the $L^{p'}$ norm here is finite and comparable to $x^{\alpha+3/2-1/p}$. Then we get

$$|U_1^{\alpha,\sigma} f(x)| \lesssim g^{\alpha}(x) \|f\|_p, \quad x > 0,$$

where

$$g^{\alpha}(x) = x^{1-1/p} \exp(-cx^2) \left\{ \begin{array}{ll}
  x^{2\sigma - 1}, & \sigma < 1/2 \\
  1 + \log^+ \frac{1}{x}, & \sigma = 1/2 \\
  (1 + x)^{1-2\sigma}, & \sigma > 1/2.
\end{array} \right.$$ 

It is easy to check that $g^{\alpha} \in L^q$ when $\sigma \geq 1/2$. The same is true for $\sigma < 1/2$ under the additional condition $\frac{1}{q'} > \frac{1}{p} - 2\sigma$. So in these cases $U_1^{\alpha,\sigma}$ is $L^p - L^q$ bounded. For $\sigma < 1/2$ and $\frac{1}{q'} = \frac{1}{p} - 2\sigma$ we have $g^{\alpha}(x) = x^{-1/q'} \exp(-cx^2)$. Since now $g^{\alpha}$ belongs to weak $L^q$, we see that $U_1^{\alpha,\sigma}$ is of weak type $(p,q)$. Now the $L^p - L^q$ boundedness follows by the Marcinkiewicz interpolation theorem.
Considering $U_{2}^{\alpha,\sigma}$, we recall that it is the dual of $U_{1}^{\alpha,\sigma}$ and use the already proved results for $U_{1}^{\alpha,\sigma}$. This gives the desired $L^{p} - L^{q}$ boundedness, except for the case $q = 1$ which we now treat separately. By Eq. 2 and Theorem 2.1 (ii),

$$|U_2^{\alpha,\sigma} f(x)| \lesssim x^{\alpha+1/2} \int_x^{\infty} y^{-\alpha-1/2} \exp \left( - cy^2 \right) \frac{y^{2\sigma-1}}{1 + \log^+ \frac{1}{y}}, \quad \sigma < 1/2 \right) \leq |f(y)| dy.$$

Integrating in $x$ and changing the order of integration produces

$$\|U_2^{\alpha,\sigma} f\|_1 \lesssim \int_0^{\infty} y^{1/p} g^\sigma(y) |f(y)| dy.$$

Since the function $y \mapsto y^{1/p} g^\sigma(y)$ belongs to $L^{p'}$, the conclusion follows by Hölder’s inequality.

4.3 $L^{p} - L^{q}$ Estimates in the Dunkl-Laguerre Setting

Let us first introduce some extra notation. For a function $f$ on $\mathbb{R}$, define $f_+$ and $f_-$ as functions on $\mathbb{R}_+$ given by $f_+(x) = f(x)$, $f_-(x) = 0$ for $x \not\in \mathbb{R}_+$. In a similar way, let $K_+^{\alpha,\sigma}$ and $K_-^{\alpha,\sigma}$ be the kernels on $\mathbb{R}_+ \times \mathbb{R}_+$ determined by $K_+^{\alpha,\sigma}(x, y) = K_-^{\alpha,\sigma}(x, y)$, $x, y > 0$. Denote the corresponding integral operators related to the measure space $(\mathbb{R}_+, d\mu_\alpha)$ by $I_+^{\alpha,\sigma}$, respectively.

Clearly, for any fixed $1 \leq p \leq \infty$,

$$\|f\|_{L^p(d\omega)} \simeq \|f_+\|_{L^p(d\mu_\alpha)} + \|f_-\|_{L^p(d\mu_\alpha)}.$$

Further, by the symmetry of the kernel, $K_+^{\alpha,\sigma}(-x, y) = K_-^{\alpha,\sigma}(x, -y)$, and the symmetry of $w_\alpha$,

$$I_+^{\alpha,\sigma} f = I_-^{\alpha,\sigma} f_+ + I_-^{\alpha,\sigma} f_-.$$

Proof of Theorem 2.6 In view of Eq. 7, the kernels $K_+^{\alpha,\sigma}(x, y)$ are comparable to $K_-^{\alpha,\sigma}(x, y)$. Thus $I_+^{\alpha,\sigma}$ satisfy the positive mapping properties from Theorem 2.2. Therefore, for the asserted $p$ and $q$ we can write

$$\|I_+^{\alpha,\sigma} f\|_{L^q(d\omega)} \simeq \|(I_+^{\alpha,\sigma} f)_+\|_{L^q(d\mu_\alpha)} + \|(I_+^{\alpha,\sigma} f)_-\|_{L^q(d\mu_\alpha)} \leq \|I_+^{\alpha,\sigma} f_+\|_{L^q(d\mu_\alpha)} + \|I_-^{\alpha,\sigma} f_-\|_{L^q(d\mu_\alpha)} \lesssim \|f_+\|_{L^p(d\mu_\alpha)} + \|f_-\|_{L^p(d\mu_\alpha)} \simeq \|f\|_{L^p(d\omega)}.$$

To show the necessity part, we observe that by Eq. 8 the kernel $K_+^{\alpha,\sigma}(x, y)$ is comparable to $K_-^{\alpha,\sigma}(x, y)$. Thus the range of admissible $p$ and $q$ from Theorem 2.2 is optimal also for $I_+^{\alpha,\sigma}$. Now, to finish the proof it suffices to notice that if $I_+^{\alpha,\sigma}$ is $L^p - L^q$ bounded, then so is $I_-^{\alpha,\sigma}$. Indeed, take a function $f$ on $\mathbb{R}_+$ and extend it to $\tilde{f}$ on $\mathbb{R}$ by setting $\tilde{f}(x) = 0$ for $x \not\in \mathbb{R}_+$. Then, assuming that $I_+^{\alpha,\sigma}$ is $L^p - L^q$ bounded,

$$\|I_+^{\alpha,\sigma} f\|_{L^q(d\mu_\alpha)} = \|(I_+^{\alpha,\sigma} \tilde{f})_+\|_{L^q(d\mu_\alpha)} \leq \|I_+^{\alpha,\sigma} \tilde{f}\|_{L^q(d\mu_\alpha)} \lesssim \|\tilde{f}\|_{L^p(d\omega)} = \|f\|_{L^p(d\mu_\alpha)}.$$

The conclusion follows.
