Abstract
We introduce a new theoretical framework to analyze deep learning optimization with connection to its generalization error. Existing frameworks such as mean field theory and neural tangent kernel theory for neural network optimization analysis typically require taking limit of infinite width of the network to show its global convergence. This potentially makes it difficult to directly deal with finite width network; especially in the neural tangent kernel regime, we cannot reveal favorable properties of neural networks beyond kernel methods. To realize more natural analysis, we consider a completely different approach in which we formulate the parameter training as a transportation map estimation and show its global convergence via the theory of the infinite dimensional Langevin dynamics. This enables us to analyze narrow and wide networks in a unifying manner. Moreover, we give generalization gap and excess risk bounds for the solution obtained by the dynamics. The excess risk bound achieves the so-called fast learning rate. In particular, we show an exponential convergence for a classification problem and a minimax optimal rate for a regression problem.

1 Introduction
Despite the extensive empirical success of deep learning, there are several missing issues in theoretical understanding of its optimization and generalizations. Even though there are several theoretical analyses on its generalization error and representation ability \cite{45, 8, 2, 65, 55}, they are not necessarily well connected with optimization procedure. The difficulties in neural network optimization stems from its non-convexity. Recently, this difficulty of non-convexity is partly resolved by considering infinite width limit of networks as performed in mean field theory \cite{57, 39} and Neural Tangent Kernel (NTK) \cite{30, 20}. These analyses deal with different scaling of parameters for taking the limit of the width, but they share a similar spirit that an appropriate gradient descent direction can be found in an over-parameterized setting until convergence.

The mean field analysis formulates the neural network training as a gradient flow in the space of probability measures over the weights. The gradient flow corresponding to a deterministic dynamics of the weights can be analyzed as an interacting particle system \cite{46, 17, 52, 53}. On the other hand, a stochastic dynamics can be formulated as McKean–Vlasov dynamics, and convergence to the global optimal is ensured by the ergodicity of this dynamics \cite{39, 40}. Intuitively, inducing stochastic noise makes the solution easier to get out of local optimal and facilitate the convergence to the global optimal. The McKean-Vlasov type analysis can be conducted not only just an ordinal stochastic gradient descent but also can be adapted to the optimal control theory. For example, \cite{75, 68, 37} analyzed the optimal solution path derived from the Hamilton-Jacobi-Bellman equation for training 2 layer neural network and ResNet.
The second regime, NTK, deals with larger scaling than the mean field regime, and the gradient
descent dynamics is approximated by that in the tangent space at the initial solution \[ 20, 21, 1, 20, 3 \].
That is, in the wide limit of the neural network, the gradient descent can seen as that in an
reproducing kernel Hilbert space (RKHS) corresponding to the neural tangent kernel, which resolves the difficulty
of non-convexity. Actually, it is shown that the gradient descent converges to the zero error solution
exponentially fast for a sufficiently large width network \[ 21, 1, 20 \]. In addition to the optimization,
it's generalization error has been also extensively studied in the NTK regime \[ 21, 1, 20, 70, 15, 16, 73, 19, 47, 32 \]. On the other hand, \[ 27 \] pointed out that nonconvexity of a deep neural network model is
essential to show superiority of deep learning over linear estimators such as kernel methods as in the
analysis of \[ 63, 28, 64 \]. Therefore, NTK regime would not be appropriate to show superiority of deep
learning over other methods such as kernel methods.

The above mentioned researches opened up new directions for analyzing deep learning optimization.
However, all of them require that the width should diverge as the sample size goes up to show the global
convergence and obtain generalization error bounds. On the other hand, a convergence guarantee for
“fixed width” training is still difficult and we have not obtained a satisfactory result that can bridge
both of under-parameterized and over-parameterized settings in a unifying manner. One way to tackle
non-convexity in a finite width situation would be stochastic gradient Langevin dynamics (SGLD)
\[ 77, 50, 22 \]. This would be useful to show the global convergence for the non-convex optimization in
deep leaning. However, the convergence rate depends exponentially to the dimensionality, which is not
realistic to analyzing neural network training that typically requires huge parameter size.

Our contribution: In this paper, we resolve these difficulties such as (i) diverging width against
sample size and (ii) curse of dimensionality for analyzing Langevin dynamics in neural network training
by formulating the neural network training as a transport map estimation problem of the parameters.
By doing so, we can deal with finite width and infinite width in a unifying manner. We also give a
generalization error bound for the solution obtained by our optimization formulation and further show
that it achieves fast learning rate in a well-specified setting. The preferable generalization error heavily
relies on similarity between a nonparametric Bayesian Gaussian process estimator and the Langevin
dynamics. More details are summarized as follows:

- **(formulation)** We formulate neural network training as a transportation map learning of weights
  (parameters) and solve this problem by infinite dimensional gradient Langevin dynamics in RKHS
  \[ 19, 14 \]. This formulation has a wide range of applications including two layer neural network,
  ResNet, Wasserstein optimal transportation map estimation and so on.

- **(optimization)** Based on this formulation, we show its global convergence for finite width and
  infinite width in a unifying manner. We give size independent convergence rate of it.

- **(generalization)** We derive the generalization error bound of the estimator obtained by our op-
timization framework. We also derive the fast learning rate in a student-teacher setup. Especially,
we show exponential convergence for classification.

2 Problem setting and model: Training parameter transfor-
mation map

In this section, we give the problem setting and notations that will be used in the theoretical analysis.
 Basically, we consider the standard supervised learning where data consists of input-output pairs \( z = (x, y) \) where \( x \in \mathbb{R}^d \) is an input and \( y \in \mathbb{R} \) is an output (or label). We may also consider a unsupervised
learning setting, but just for the presentation simplicity, we consider a supervised learning. Suppose
that we are given \( n \) i.i.d. observations \( D_n = (x_i, y_i)_{i=1}^n \) distributed from a probability distribution \( P \),
the marginal distribution of which with respect to \( x \) is denoted by \( P_X \). We denote \( X = \text{supp}(P_X) \). To
measure the performance of a trained function \( f \), we use a loss function \( \ell : \mathbb{R} \times \mathbb{R} \to \mathbb{R} \)
\((y, f) \mapsto \ell(y, f)\) and define the expected or empirical risk as \( \mathcal{L}(f) := \mathbb{E}_{Y \sim X}[\ell(Y, f(X))] \),
\( \hat{\mathcal{L}}(f) := \frac{1}{n} \sum_{i=1}^n \ell(y_i, f(x_i)) \).
As in the standard deep learning, we optimize the training risk \( \hat{\mathcal{L}} \). Our theoretical interest is to bound the following errors for an estimator \( \hat{f} \):

\[
\text{Excess risk: } \mathcal{L}(\hat{f}) - \inf_{f: \text{measurable}} \mathcal{L}(f), \quad \text{Generalization gap: } \mathcal{L}(\hat{f}) - \hat{\mathcal{L}}(\hat{f}).
\]

In a typical situation, the generalization gap is bounded as \( O(1/\sqrt{n}) \) via VC-theory type analysis \cite{42}, for example. On the other hand, the excess risk can be faster than \( O(1/\sqrt{m}) \), which is known as a fast learning rate \cite{11, 38, 25}. The population \( L_2 \)-norm with respect to \( P \) is denoted by \( \|f\|_{L_2} := \sqrt{\mathbb{E}_{Z \sim P}[f(Z)^2]} \) and the sup-norm on the domain of the input distribution \( P_X \) is denoted by \( \|f\|_{\infty} := \sup_{x \in \text{supp}(P_X)} |f(x)| \).

2.1 Introductory setting: mean field training of two layer neural network

Here, we explain the motivation of our theoretical framework by introducing mean field analysis of two layer neural networks. Let us consider the following two layer neural network model:

\[
f_{\Theta}(x) = \frac{1}{M} \sum_{m=1}^{M} a_m \sigma(w_m^T x).
\]

(1)

where \( \sigma : \mathbb{R} \to \mathbb{R} \) is a smooth activation function, \( (a_m)_{m=1}^{M} \subset \mathbb{R} \) is the set of weights in the second layer which we assume is fixed for simplicity, and \( \Theta = (w_m)_{m=1}^{M} \subset \mathbb{R}^d \) is the set of weights in the first layer. We aim to minimize the following regularized empirical risk with respect to \( \Theta \) and analyze the dynamics of gradient descent updates:

\[
\min_{\Theta} \hat{\mathcal{L}}(f_{\Theta}) + \frac{\lambda}{2M} \sum_{m=1}^{M} \|w_m\|^2.
\]

The stochastic gradient descent (SGD) update for optimizing \( \hat{\mathcal{L}}(f_{\Theta}) \) with respect to \( \Theta \) is reduced to

\[
u_{m(t+1)} = \nu_{m(t)} - \eta \left( \frac{\lambda}{M} \nu_{m(t)} + \nabla_{w_m} \hat{\mathcal{L}}(f_{\Theta(t)}) \right) + \sqrt{\frac{\eta}{\beta_t}} \epsilon_t^{(m)}
\]

(2)

where \( \nabla_{w_m} \hat{\mathcal{L}}(f_{\Theta(t)}) = \frac{\eta}{\sqrt{t}} \sum_{i=1}^{n} x_i \sigma'(w_m^{(i)\top} x_i) \ell'(y_i, f_{\Theta(t)}(x_i)) \) and \( \epsilon_t^{(m)} \) is an i.i.d. Gaussian noise mimicking the deviation of the stochastic gradient. Here, \( \eta > 0 \) is a step size and \( \beta > 0 \) is an inverse temperature parameter. This could be time discretized version of the following continuous time stochastic differential equation (SDE): 

\[
dw_m(t) = -\left( \frac{\lambda}{M} w_m(t) + \nabla_{w_m(t)} \hat{\mathcal{L}}(f_{\Theta(t)}) \right) dt + \sqrt{\frac{\eta}{\beta_t}} dB_t^{(m)}
\]

where \( (B_t^{(m)})_t \) is a \( d \)-dimensional Brownian motion. In the mean field analysis, this optimization process is casted to an optimization of probability distribution over the parameters \cite{39, 40, 46, 17} based on the following integral representation of neural networks:

\[
f_{\rho}(x) := \int_{\mathbb{R}^d} a \sigma(w^T x) d\rho(w),
\]

(3)

where \( \rho \) is a Borel probability measure defined on the parameter space \( \mathbb{R}^d \) and the parameter in the second layer is fixed to a constant \( a \in \mathbb{R} \) just for presentation simplicity. The time evolution of the distribution \( \rho \) is deduced from the optimization dynamics with respect to each “particle” given by

\[
dW(t) = -\left( \lambda W(t) + \frac{1}{n} \sum_{i=1}^{n} x_i \sigma'(W(t)^T x_i) \ell'(y_i, f_{\rho(t)}(x_i)) \right) dt + \sqrt{\beta_t^{-1}} dB_t,
\]

where \( \rho(t) \) is the probability law of \( W(t) \in \mathbb{R}^d \) with an initial distribution \( W_0 \sim \rho_0 \), which is one of McKean-Vlasov processes. We can see that this equation is space-time continuous limit of the
update Eq. \( \text{(2)} \). Importantly, \( \rho_t \) admits a density function \( \pi_t \) obeying the so-called continuity equation \([39, 40]\). The usual finite width network is regarded as a finite sum approximation of the integral representation (Eq. \( \text{(3)} \)). As a consequence, the convergence analysis needs to take limit of infinite width to approximate the absolutely continuous distribution \( \rho_t \). Hence, a finite width dynamics is outside the scope of mean field analysis. This is due to the fact that an independent noise is injected to each particle regardless the location of particle: the diffusion \( B_t \) is independently and identically applied to each realized path \( \{W(t) \mid t \geq 0\} \) (interaction between particles is induced only through gradient). However, in a real neural network training, the noise induced by stochastic gradient has high correlation between each node. Thus, we need a different approach.

**Lift of McKean-Vlasov process** Our core idea is to “lift” the stochastic process \( W(t) \) as a process of a function with the initial value \( W(0) \). For each \( W(0) = w_0 \), the particle’s location at time \( t \) is determined by \( W(t) = W(t, w_0) \). This means that the process generates a function \( w_0 \mapsto W(t, w_0) \) with respect to the initial solution \( w_0 \). By considering the stochastic process of this function itself directly, the dynamics is transformed to an *infinite dimensional stochastic differential equation*, which has been studied especially in the stochastic partial differential equation \([19]\). In other words, we try to estimate a map from the initial parameters to the solution at time \( t \) instead of analyzing each particle’s behavior.

From this perspective, we can directly regularize the smoothness of the trajectory, especially, we can incorporate a smoothed noise of the dynamics by utilizing a spatially correlated Gaussian process in the space of functions on parameters. Let \( W_i(w) = W(t, w) \) and we regard \( W_i \) as a member of \( L_2(\rho_0) \) space. Then, \( f_{\rho_0} \) can be rewritten by

\[
    f_{W_i}(x) := \int_{\mathbb{R}^d} a\sigma(W_i(w)\top x)\,d\rho_0(w) = \int_{\mathbb{R}^d} a\sigma(w\top x)\,dW_i \rho_0(w),
\]

where \( W_i \rho_0 \) is the pushforward of the measure \( \rho_0 \) by the map \( W_i \), i.e., \( f_{\rho_0}(B) := \mu \circ f^{-1}(B) = \mu(f^{-1}(B)) \) for a Borel measurable map \( f : \mathbb{R}^d \rightarrow \mathbb{R}^d \), a Borel measure \( \mu \), and a Borel set \( B \subset \mathbb{R}^d \). By using this notation, the stochastic process we consider can be written as

\[
    dW_t = -(AW_t + \nabla W \hat{E}(f_{W_t}))dt + \sqrt{\beta^{-1}}d\xi_t,
\]

where \( \nabla W \hat{E}(f_{W_t}) \) is the Frechet derivative of \( \hat{E}(f_{W_t}) \) with respect to \( W \) in the space of \( L_2(\rho_0) \). In our setting, which is given by \( \nabla W \hat{E}(f_{W_t})(w) = a_x \sum_{i=1}^n x_i\sigma'(W(w)\top x_i)\epsilon(y_i, f_W(x_i)) \) \((\xi_t)_{t} \) is a cyllindric Brownian motion in \( L_2(\rho_0) \) \([19]\), which is an infinite dimensional Brownian motion and will be defined rigorously later on. In practical deep learning, the regularization term \( AW_t \) is induced by several mechanisms such as weight decay \([35]\), dropout \([52, 73]\), batch-normalization \([29]\). As a result, the regularization term \( AW_t \) introduces spatial correlation between particles unlike the McKean-Vlasov process.

Then, training two layer neural networks is formulated as optimizing the map \( W : w \in \mathbb{R}^d \mapsto W(w) \in \mathbb{R}^d \) with the initial condition \( W_0 = \mathbb{I} \) (identity map). This dynamics is well analyzed and guaranteed to converge at least a stationary distribution (a.k.a., invariant measure) under mild assumptions \([18, 58, 26, 56, 26]\) which is useful to show convergence to a (near) global optimal.

**Remark 1.** We would like to emphasize that our formulation admits a finite width neural network training by setting the initial distribution \( \rho_0 \) as a discrete distribution \( \rho_0 = \frac{1}{M} \sum_{m=1}^M \delta_{w_m} \) for a Dirac measure \( \delta_{w_m} \) which has probability \( 1 \) on a point \( w_m \). In this situation, optimizing the map \( W_t \) corresponds to optimizing the finite width model \([1]\) because \( \rho_t = W_t \rho_0 = \frac{1}{M} \sum_{m=1}^M \delta_{W_t(w_m)} \) which is still a discrete distribution throughout entire \( t \in \mathbb{R}_+ \). This is remarkably different from both mean field analysis and NTK analysis that essentially take infinite width limits: mean field analysis in \([34, 16]\) requires \( M = \Omega(e^T) \) for a time horizon \( T \) and NTK requires \( M = \Omega(poly(n)) \) \([79]\).
General formulation of our optimization problem

Here, we describe mathematical details of optimizing the transportation map in more general formulation and give a practical algorithm of the corresponding GLD. We assume that the map $W_t(\cdot)$ is included in a separable Hilbert space $\mathcal{H}$ with norm $\|\cdot\|_{\mathcal{H}}$ and an inner product $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ (in the previous section, $\mathcal{H} = L_2(\rho_0)$). The Hilbert space $\mathcal{H}$ consists of functions whose domain is a set $\mathcal{W}$ and whose range is $\mathcal{W}$ (in the previous example, $\mathcal{W} = \mathbb{R}^d$ and $\mathcal{W} = \mathbb{R}^d$). Since a function $w \in \mathcal{H}$ has no smoothness condition in typical settings, we consider a more “regulated” subspace of $\mathcal{H}$. Such a subspace is denoted by $\mathcal{H}_K$ and given by

$$\mathcal{H}_K := \left\{ \sum_{k=0}^{\infty} \alpha_k e_k \mid \sum_{k=0}^{\infty} \alpha_k^2 / \mu_k < \infty \right\},$$

where $(e_k)_{k=0}^{\infty}$ is an orthonormal basis of $\mathcal{H}$ and $(\mu_k)_{k=0}^{\infty}$ is a non-increasing non-negative sequence. We equip an inner product $\langle \cdot, \cdot \rangle_{\mathcal{H}_K}$ to the space $\mathcal{H}_K$ defined by $\langle f, g \rangle_{\mathcal{H}_K} = \sum_{k=0}^{\infty} \alpha_k \beta_k / \mu_k$ for $f = \sum_{k=0}^{\infty} \alpha_k e_k \in \mathcal{H}_K$ and $g = \sum_{k=0}^{\infty} \beta_k e_k \in \mathcal{H}_K$. Correspondingly, the norm $\| \cdot \|_{\mathcal{H}_K}$ is defined from the inner product. When $\mathcal{H} = L_2(\rho_0)$, $\mathcal{H}_K$ becomes a reproducing kernel Hilbert space (RKHS) corresponding to a kernel function $K(x, y) = \sum_{k=0}^{\infty} \mu_k e_k(x) e_k(y)$ where $x, y \in \mathbb{R}^d$. That is, we have the reproducing property $\langle K(x, \cdot), W \rangle_{\mathcal{H}_K} = W(x)$ for each $W \in \mathcal{H}_K$. Based on the norm $\| \cdot \|_{\mathcal{H}_K}$, we define an unbounded linear operator $A : \mathcal{H} \to \mathcal{H}$ as

$$Af = \lambda \sum_{k=0}^{\infty} \frac{\alpha_k}{\mu_k} e_k,$$

for $f = \sum_{k=0}^{\infty} \alpha_k e_k \in \mathcal{H}$. We note that $Af = \lambda \nabla f \| f \|_{\mathcal{H}_K}^2$ which is a Frechet derivative of $\lambda \| \cdot \|^2_{\mathcal{H}_K}$ in $\mathcal{H}$ (which is the derivative of the RKHS norm, if $\mathcal{H}_K$ is an RKHS). We assume that for each $W \in \mathcal{H}$, there exits a function $f_W : \mathbb{R}^d \to \mathbb{R}$ as in Eq. 4, and we basically aim to minimize the regularized empirical risk

$$\hat{L}(f_W) + \lambda \| W \|_{\mathcal{H}_K}^2.$$

By abuse of notation, we denote by $\hat{L}(W)$ indicating $\hat{L}(f_W)$. To execute this non-convex optimization, we use the GLD in the infinite dimensional Hilbert space $\mathcal{H}$ as introduced in Eq. 5. Here, $(\xi_t)_{t \geq 0}$ in Eq. 5 is the cylindrical Brownian motion defined as $\xi_t = \sum_{k \geq 1} B_t^{(k)} e_k$ where $(B_t^{(k)})_{t \geq 0}$ is a real valued standard Brownian motion and they are independently identical for $k = 0, 1, 2, \ldots$ Then, we can formally define the GLD in the infinite dimensional Hilbert space $\mathcal{H}$ as Eq. 5:

$$dW_t = -(AW_t + \nabla_W \hat{L}(W_t))dt + \sqrt{\beta^{-1}}d\xi_t.$$

Since this is defined on a continuous time domain, we introduce a discrete time implicit Euler scheme for practical implementation:

$$W_{k+1} = W_k - \eta (AW_{k+1} + \nabla_W \hat{L}(W_k)) + \sqrt{\frac{\eta}{\beta}} e_k$$

$$\Leftrightarrow W_{k+1} = S_{\eta} \left( W_k - \eta \nabla_W \hat{L}(W_k) + \sqrt{\frac{\eta}{\beta}} e_k \right),$$

where $\eta > 0$ is the step size and $S_{\eta} = (\mathbb{I} + \eta A)^{-1}$. We can see that the “regularization effect” $AW$ induces the spacial smoothness of the noise of the gradient. It is known that under some assumption (Assumption 1 below is sufficient), the process 5 has a unique invariant measure $\pi_{\infty}$ given by

$$\frac{d\pi_{\infty}}{d\nu_\beta}(W) \propto \exp(-\beta \hat{L}(W)),$$

1 More natural modeling would be that the regularization $A$ and the covariance of $\xi_t$ depend on the current solution $W_t$, but we consider this simplest model for technical tractability.
where \( \nu_\beta \) is the Gaussian measure on \( \mathcal{H} \) with mean 0 and covariance \((\beta A)^{-1}\) (see \[19\] for its derivation and the rigorous definition of the Gaussian measure on a Hilbert space). In a special situation where \( \beta = n \), \( \lambda = 1/n \) and \( \beta \hat{L}(W) \) is a log-likelihood function of some model, this invariant measure is nothing but the Bayes posterior distribution for a Gaussian process prior corresponding to the RKHS \( \mathcal{H}_K \). Remarkably, this formulation can be applied to several problems other than training two layer neural networks:

- Ordinary nonparametric regression model: \( \mathcal{W} = \mathbb{R}^d, \mathcal{W} = \mathbb{R} \) and
  \[
  f_W(x) = W(x).
  \]

- Two layer neural networks (continuous topology): \( \mathcal{W} = \mathcal{W} = \mathbb{R}^d \) and
  \[
  f_W = \int_{\mathbb{R}^d} a(w)\sigma(W(w)^\top x)\,d\rho_0(w).
  \]

- Two layer neural networks (discrete topology): \( \mathcal{W} = \{1, 2, 3, \ldots\}, \mathcal{W} = \mathbb{R}^d \) and
  \[
  f_W = \sum_{m=1}^{\infty} a_m\sigma(W(m)^\top x).
  \]

- ResNet: \( \mathcal{W} = \mathbb{R}^d \times \{1, \ldots, T\}, \mathcal{W} = \mathbb{R}^d \) and
  \[
  f_W(x) = u^\top \left( \mathbb{1} + \int_{\mathbb{R}^d} a_{w,T}\sigma(W(w,T)^\top x)\,d\rho_0(w) \right) \circ \cdots \circ \left( \mathbb{1} + \int_{\mathbb{R}^d} a_{w,1}\sigma(W(w,1)^\top x)\,d\rho_0(w) \right),
  \]
  where \( u \in \mathbb{R}^d \) and \( a_{w,t} \in \mathbb{R}^d \) for \( w \in \mathbb{R}^d \) and \( t \in \{1, \ldots, T\} \).

- Wasserstein optimal transportation map: \( \mathcal{W} = \mathcal{W} = \mathbb{R}^d \) and
  \[
  f_W(x) = W(x).
  \]

For random variables \( X \) and \( Y \) obeying distributions \( P \) and \( Q \) respectively: \( W^2(P,Q) = \min_{W:Q=f_W \mathbb{P} \mathbb{E}_X \sim P[\|X - f_W(X)\|^2]} \).

### 3 Optimization error bound map learning

To show convergence of the dynamics \([11]\), we utilize the recent result given by \[44\]. Let \( \|W\|_\varepsilon := (\sum_{k \geq 0} (\mu_k)^{2\varepsilon}(W,e_k)^2_\mathcal{H})^{1/2} \) and \( P_N W := \sum_{k=0}^{N-1} \langle W, e_k \rangle \mathcal{H} e_k \) for \( W \in \mathcal{H} \) where \( (e_k)_k \) is the orthonormal system of \( \mathcal{H} \). Accordingly, let \( \mathcal{H}_N \) be the image of \( P_N \): \( \mathcal{H}_N = P_N \mathcal{H} \).

**Assumption 1.**

(i) (Eigenvalue condition) There exists a constant \( c_\mu \) such that \( \mu_k \leq c_\mu (k + 1)^{-2} \).

(ii) (Boundedness and Smoothness) There exist \( B, M > 0 \) such that the gradient of the empirical risk is bounded by \( B \) and is \( M \)-Lipschitz continuous with \( \alpha \in (1/4, 1) \) almost surely:

\[
\|\nabla \hat{L}(W)\|_\mathcal{H} \leq B \quad (\forall W \in \mathcal{H}), \quad \|\nabla \hat{L}(W) - \nabla \hat{L}(W')\|_\mathcal{H} \leq L\|W - W'\|_\alpha \quad (\forall W, W' \in \mathcal{H}).
\]

(iii) (Third order smoothness \[13\], Assumption 2.7) Let \( \hat{L}_N : \mathcal{H}_N \to \mathbb{R} \) be \( \hat{L}_N = \hat{L}(P_N W) \). \( \hat{L} \) is three times differentiable, and there exists \( \alpha' \in \{0, 1\}, C_{\alpha'} \in (0, \infty) \) such that for all \( N \in \mathbb{N} \) and \( \forall W, h, k \in \mathcal{H}_N \), \( \|\nabla^3 \hat{L}_N(W) \cdot (h, k)\|_{\mathcal{H}} \leq C_{\alpha'} \|h\|_{\mathcal{H}} \|k\|_{\mathcal{H}}, \quad \|\nabla^3 \hat{L}_N(W) \cdot (h, k)\|_{\mathcal{H}} \leq C_{\alpha'} \|h\|_{-\alpha'} \|k\|_{\mathcal{H}} \) (a.s.), where \( \nabla^3 \hat{L}_N(W) \) is the third-order derivative, we identify it with third-order linear form, and we also write \( \nabla^3 \hat{L}_N(W) \cdot (h, k) \) for the Riesz representor of \( l \in \mathcal{H} \mapsto \nabla^3 \hat{L}_N(W) \cdot (h, k, l) \).
Then, we can show the following weak convergence rate. Let \( \pi_k \) be the probability measure on \( \mathcal{H} \) corresponding to the distribution of \( W_k \).

**Proposition 1.** Assume Assumption\(^7\) holds and \( \beta > \eta \). Suppose that \( \exists \tilde{R} > 0, 0 \leq \ell(Y, f_W(X)) \leq \tilde{R} \) for any \( W \in \mathcal{H} \) (a.s.). Let \( \rho = \frac{1}{\epsilon_{\lambda_0}/\mu_0} \) and \( b = \frac{2\tilde{R}B + C}{\mu_0} \). Then, for \( \beta > \eta \), we have \( \Lambda^* \leq \frac{\min(\frac{\rho}{\eta}, \frac{1}{\epsilon_0})}{4 \log(\epsilon_{\lambda_0}/(1-\delta))} \delta \) and \( C_W = \kappa[\tilde{V} + 1] + \frac{\sqrt{2(\beta + b)}}{\sqrt{\beta}} \) where \( 0 < \delta < 1 \) satisfying \( \delta = \Omega(\exp(-\Theta(\lambda^{-1}(\beta))) \), \( \tilde{b} = \max\{b, 1\} \), \( \kappa = \tilde{b} + 1 \) and \( \tilde{V} = 4b/(\sqrt{1+\rho^{1/5})}/2-\rho^{1/5}) \), and for any \( 0 < a < 1/4 \), the following convergence bound holds for almost sure observation \( D_n \): for either \( L = \mathcal{L} \) or \( \mathcal{L} = \tilde{\mathcal{L}} \),

\[
\mathbb{E}_{W_k \sim \pi_k} [L(W_k)] - \mathbb{E}_{W \sim \pi_\infty} [L(W)] \leq C_1 \left[ C_W \exp(-\Lambda^*_\eta k) + \frac{\sqrt{\beta}}{\Lambda^*_0} \eta^{1/2-a} \right] =: \Xi_k,
\]

where \( C_1 \) is a constant depending only on \( c_\mu, B, L, \alpha', a, \tilde{R} \) (independent of \( \eta, k, \beta, \lambda \)).

We utilized the theories of \( [44] \) as the core technique to show this proposition. Its complete proof is given in Appendix \( A \). We can see that as \( k \) goes to infinity the first term of the right hand side converges exponentially, and as the step size \( \eta \) goes to 0, the second term converges arbitrary close to the rate of \( \sqrt{n} \). It is known that the convergence rate with respect to \( \eta \) is optimal \( [14] \). Therefore, if we choose sufficiently small \( \eta \) and sufficiently large \( k \), we can sample \( W_k \) that obeys nearly the invariant measure \( \pi_\infty \). As we will see later, sample from \( \pi_\infty \) has a nice property in terms of generalization. As we have remarked in Remark \( 1 \) the convergence is guaranteed even for the finite width neural network setting, i.e., \( \rho_0 \) is a discrete distribution in the model \( 11 \). This is much advantageous against existing framework such as mean field analysis and NTK.

### 4 Generalization error analysis

#### Generalization gap bound

Here, we analyze the generalization error of the solution of \( W_k \) obtained by the dynamics (6).

**Theorem 1.** Assume Assumption\(^7\) holds with \( \beta > \eta \), and assume that the loss function is bounded, i.e., there exits \( \tilde{R} > 0 \) such that \( \forall W \in \mathcal{H}, 0 \leq \ell(Y, f_W(X)) \leq \tilde{R} \) (a.s.). Then, for any \( 1 > \delta > 0 \), with probability \( 1 - \delta \), the generalization error is bounded by

\[
\mathbb{E}_{W_k} [\mathcal{L}(W_k)] \leq \mathbb{E}_{W_k} [\tilde{\mathcal{L}}(W_k)] + \frac{R^2}{\sqrt{n}} \left[ 2 \left( 1 + \frac{2\beta}{\sqrt{n}} \right) + \log \left( 1 + e^{R^2/2} \right) \right] + 2\Xi_k.
\]

The proof is given in Appendix \( 13 \). To prove this, we used a PAC-Bayes stability bound \( [51] \). From this theorem, we have that the generalization error is bounded by \( O(1/\sqrt{n}) \) and the optimization error \( \Xi_k \). The \( O(1/\sqrt{n}) \) term is the generalization gap for the stationary distribution, and as \( k \) goes to infinity, the total generalization gap converges to this one. \( [43] \) also showed a PAC-Bayesian stability bound for a finite dimensional Langevin dynamics (roughly speaking, their bound is \( O(\sqrt{\beta B^2/(n\lambda)}) \)), but their proof technique is quite different from ours. Our proof analyzes the generalization error under the stationary distribution of the dynamics and bounds the gap between the stationary distribution and the current solution, while \( [43] \) evaluated the bound by “accumulating” the error through the updates without analyzing the stationary distribution.

**Excess risk bound: fast learning rate** Next, we bound the excess risk. Unlike the \( O(1/\sqrt{n}) \) convergence rate of the generalization gap bound, we can derive a fast learning rate which is faster than \( O(1/\sqrt{n}) \) in a setting of realizable case, i.e., a student-teacher model, for the excess risk instead of the generalization gap. As a concrete example, we keep the following two layer neural network model

\[^2\] Throughout the paper, we consider the natural logarithm: \( \log(x) \equiv \log_e(x) \).
in our mind. For a map $W : \mathbb{R}^{d_1} \to \mathbb{R}^{d_2}$, let a “clipped map” $\bar{W}$ be $\bar{W}(w) := R \times \text{sig}(W(w)/R)$, where $R \geq 1$ is a constant and $\text{sig}()$ is the sigmoid function $1/(1 + e^{-x})$ applied elementwise. Then, the following two layer neural network model falls into our analysis:

$$f_W(x) := \int_{\mathbb{R} \times \mathbb{R}^d} \bar{W}_2(a)\sigma(\bar{W}_1(w)^\top x)d\rho_0(a, w) \tag{8}$$

for $W = (W_1, W_2) : \mathbb{R}^d \times \mathbb{R} \to \mathbb{R}^d \times \mathbb{R}$ and an activation function $\sigma$ that is 1-Lipschitz continuous and included in a Hölder class $C^\gamma(\mathbb{R})$. Here, we used the clipping operation only for a technical reason because the current convergence analysis of the infinite dimensional Langevin dynamics requires a boundedness condition. This could be removed if we could show its convergence under more relaxed conditions. The fast learning rate analysis is not restricted to the two layer model, but it can be applied as long as the following statement is satisfied (e.g., ResNet).

**Lemma 1.** For the model \(8\), if \(\|x\| \leq D\) for any \(x \in \text{supp}(P_X)\), then it holds that \(\|f_W - f_W'\|_\infty \leq (1 + RD)\|W - W'\|_{L_2(\rho_0)}\) where \(\|W - W'\|_{L_2(\rho_0)} := \int \|W((a, w)) - W'((a, w))\|^2d\rho_0(a, w)\).

The proof is given in Appendix C. This lemma indicates that to estimate a function \(f_W'\), its estimation error can be bounded by the estimation error of the parameter \(W\). To ensure the smooth gradient assumption [Assumption (iii)] and characterize the estimation accuracy precisely by the model complexity, we consider an RKHS with “smoothness” parameter \(\gamma\) as the model of \(W\). Let $T_K : \mathcal{H} \to \mathcal{H}$ be a linear bounded operator such that $\langle T_K h, h' \rangle_{\mathcal{H}} = \sum_{k=0}^{\infty} \mu_k \alpha_k \alpha'_k$ for $h = \sum_k \alpha_k e_k$ and $h' = \sum_k \alpha'_k e_k$. Let the range of power of $T_K$ be $\mathcal{H}_{K^\gamma}$ as $\{f = T_K^{\gamma/2} h \mid h \in \mathcal{H}\}$ for $\gamma > 0$. We can see that $\gamma = 1$ corresponds to $\mathcal{H}_K$ and $\gamma$ controls the “complexity” of $\mathcal{H}_{K^\gamma}$, that is, if $\gamma < 1$, then $\mathcal{H}_K \hookrightarrow \mathcal{H}_{K^\gamma}$, and otherwise, $\mathcal{H}_{K^\gamma} \hookrightarrow \mathcal{H}_K$. We consider a problem of optimizing $\hat{\mathcal{L}}(f_W)$ or $\mathcal{L}(f_W)$ with respect to $W$ in the model $\mathcal{H}_{K^\gamma}$.

**Example 1.** As an example, the model given above includes a situation in which $\rho_0$ is a discrete distribution represented as $d\rho_0 = \sum_{m=0}^{\infty} \alpha_m \delta_{(a_m^{(0)}, w_m^{(0)})}$ where $\alpha_m$ is the probability mass of the $m$-th node ($q_m \geq 0$, $\sum_{m=0}^{\infty} q_m = 1$), $\delta_{(a, w)}$ is the Dirac measure that has probability mass 1 on $(a, w) \in \mathbb{R} \times \mathbb{R}^d$, and $\{(a_m^{(0)}, w_m^{(0)})\}_{m=0}^{\infty}$ is the initial weight; that is, by writing $W_1(w_m^{(0)}) = w_{1,m}$ and $W_2(a_m^{(0)}) = w_{2,m}$,

$$f_W(x) = \sum_{m=0}^{\infty} q_m \bar{W}_2(a_m^{(0)})\sigma(\bar{W}_1(w_m^{(0)})^\top x) = \sum_{m=0}^{\infty} q_m \bar{w}_{2,m}\sigma(\bar{w}_{1,m}^\top x).$$

Note that by setting $q_m = 0$ for $m \geq M$ with some $M \in \mathbb{N}$, the model is reduced to a finite width neural network $f_W(x) = \sum_{m=0}^{M} q_m \bar{w}_{2,m}\sigma(\bar{w}_{1,m}^\top x)$. In this case, $W = (W_1, W_2)$ can be identified with vectorization of concatenation of $(w_{1,m}, w_{2,m})_{m=1}^{\infty}$ and we can induce the RKHS norm as

$$\|W\|_{\mathcal{H}_K}^2 = \sum_{m=0}^{\infty} \frac{1}{\mu_m}(w_{2,m}^2 + \|w_{1,m}\|^2).$$

Then, it holds that $T_K^{\gamma/2}W = (\mu^{\gamma/2} w_{1,m}, \mu^{\gamma/2} w_{2,m})$, which yields

$$f_{T_K^{\gamma/2}W}(x) = \sum_{m=0}^{\infty} q_m (\mu_m^{\gamma/2} w_{2,m})\sigma((\mu_m^{\gamma/2} w_{1,m})^\top x).$$

Our formulation includes not only the integral representation of neural network but also the (“usual”) discretized neural network model with either finite or infinite width. Our analysis reveals the global
convergence of the Langevin dynamics and its generalization error under a proper regularization of the weight. Our model also covers a situation where $W_2(a)$ is a constant, e.g., $W_2(a) = 1$. In that case, the model can be given as

$$f_{T_K^{1/2}W}(x) = \sum_{m=0}^{\infty} g_m \sigma \left( (\gamma_m^{1/2}w_{1,m})^T x \right).$$

**Assumption 2** (Bernstein condition and predictor condition [72, 7]). The loss function $\ell(y, \cdot)$ is included in $C^3(\mathbb{R})$ for any $y \in \text{supp}(p_Y)$. The Bernstein condition is satisfied: there exist $C_B > 0$ and $s \in (0, 1]$ such that for any $f_W$ in the model,

$$E[(\ell(Y, f_W(X)) - \ell(Y, f^*(X)))^2] \leq C_B (\mathcal{L}(f_W) - \mathcal{L}(f^*))^s.$$

Moreover, we assume that, for any $h : \mathbb{R}^d \to \mathbb{R}$ and $x \in \text{supp}(p_X)$, it holds that

$$E_{Y|X=x} \left[ \exp \left( -\frac{\beta}{n} (\ell(Y, h(x)) - \ell(Y, f^*(x))) \right) \right] \leq 1.$$

The first assumption is called Bernstein condition. We can show that this condition is satisfied by the logistic loss and the squared loss with bounded $f_W$ and $f^*$ (Theorem 3). The second assumption is called predictor condition [72] and can be satisfied if $\ell$ is a log-likelihood function and the model is correctly specified (that is, the true conditional probability density (or probability mass) $p(y|x)$ is expressed as $p(y|x) \simeq \exp(-\ell(y, f^*(x)))$). To extend the theory to misspecified situations, we need the second assumption. For example, if we use a squared loss in a regression problem whereas the model can be given as

$$C_{\text{label noise}}$$

where, if there does not exist $h : \mathbb{R} \to \mathbb{R}^d$ such that for any $f_W$ in the model,

$$\mathcal{L}(f_W) - \mathcal{L}(f^*)^s.$$

Theorem 2. Assume $\mathbb{E}$ hold, $|x| \leq D$ ($\forall x \in \mathcal{X}$), $\gamma > 1/2$, $\beta > \eta$ and $\beta \leq n$. Assume also $0 \leq \ell(Y, f(X)) \leq R$ (a.s.) for any $f = f_W$ ($W \in \mathcal{H}$) and $f = f^*$. Let $\alpha := 1/\{2(\gamma + 1)\}$ and $\theta$ be an arbitrary real number satisfying $0 < \theta < 1 - \alpha$. We define

$$\epsilon^* := \inf \{ \epsilon > 0 : \phi_{\beta,\lambda}(\epsilon) \leq \beta \epsilon^2 \} \lor n^{-\theta}$$.  

Then, the expected excess risk is bounded as

$$E_{D^n} [\mathcal{L}(W_k) - \mathcal{L}(f^*)] \leq C \left[ \epsilon^{*2} \lor \left( \frac{\sigma^2}{n} \epsilon^{*2} + \frac{1}{\frac{1}{\beta} + \frac{1}{\lambda}} (\lambda \beta)^{\frac{2\beta}{\alpha+\beta}} \right)^{1/n} \lor \frac{1}{n} \right] + \Xi_k, \quad (9)$$

where $C$ is a constant independent of $n, \beta, \lambda, \eta, k$.

The proof is given in Appendix D2. It is proven by using the technique of nonparametric Bayes contraction rate analysis [23, 63, 70]. However, we cannot adapt these existing techniques because (i) the loss function is not necessarily the log-likelihood function, (ii) the inverse temperature is generally different from the sample size. In that sense, our proof is novel to derive an excess risk for (i) misspecified models, and (ii) stochastic estimator with a general inverse temperature parameter.

If the bias is not zero, i.e., $\inf_{W \in \mathcal{H}} \mathcal{L}(W) - \mathcal{L}(f^*) = \delta_0 > 0$, then we may choose $\epsilon^* = \Theta(\delta_0)$ because $\phi_{\beta,\lambda}(\epsilon)$ is finite for $\epsilon^2 > \delta_0$ and infinite for $\epsilon^2 < \delta_0$. Thus, a misspecified setting is covered.
(i) Example of fast rate: Regression Here, we apply the general result to a nonparametric regression problem by the neural network model. We consider the following nonparametric regression model:

\[ y_i = f_W(x_i) + \epsilon_i, \quad W^* \in \mathcal{H} \]

where \( \epsilon_i \) is an i.i.d. noise with mean 0 and \( |\epsilon_i| \leq C < \infty \) (a.s.). To estimate \( f_W \), we employ the squared loss \( \ell(y, f) = (y - f)^2 \). Then, we can easily confirm that \( f^* \) is achieved by \( f_W \), via a simple calculation: \( \arg\min_f \mathcal{L}(f) = f_W \). Moreover, for the squared loss, \( s = 1 \) is satisfied as remarked just after Assumption \ref{assumption:2}. Moreover, we further assume that \( W^* \in H_{K^{n+1}} \) for \( \theta < 1 - \hat{\alpha} \). Then, the “bias” and “variance” terms can be evaluated as

\[
\inf_{h_0 \in H_{K^n}} \mathcal{L}(h_0) - \mathcal{L}(f^*) \leq 2 \lambda \beta \|h_0\|^2_{H_{K^n}} \leq \lambda \beta \epsilon^{2(\alpha + \frac{d}{2})} - \log(\epsilon) - \log(\epsilon) - \frac{c}{\epsilon^2}.
\]

Accordingly, we can show the following excess risk bound:

\[
E[D^\alpha][E(W_1/\mathcal{L}(W_1) - \mathcal{L}(f^*))] \leq \max \left\{ \left(\frac{(\alpha \beta + d/2)\epsilon}{\lambda \beta \epsilon}n^{-1/\lambda \beta - 1}, \lambda \beta \epsilon - 1/n \right) \right\} + \Xi_k,
\]

(see Appendix \ref{appendix:D} for the derivation). In particular, if \( \beta = \lambda^{-1} = n \), then this convergence rate can be rewritten as \( n^{-1/\lambda \beta - 1} \), which can be faster than \( 1/\sqrt{n} \) and is controlled by the “difficulty” of the problem \( \hat{\alpha} \) and \( \theta \).

Remark 2. As an example, if the RKHS \( H_{K^n} \) is a Sobolev space \( W^{\alpha+d/2}(\mathbb{R}^d) \) with regularity parameter \( \alpha + d/2 \) (more precisely, each output \( W_i(\cdot) \) is a member of a Sobolev space) and \( \mathcal{H} \) is \( L_2(\rho_0) \), then we can set \( \alpha = \frac{d}{\lambda + d} \). If the true parameter \( W^* \) is included in another Sobolev space \( W^\beta(\mathbb{R}^d) \) for \( \beta \leq \alpha \), then we may choose \( \theta = 2\beta/(2\alpha + d) \) and the convergence rate is bounded by \( n^{-\min(\alpha, \beta)/(2\alpha + d)} \), which coincides with the posterior contraction rate of Gaussian process estimator derived in \cite{ bishop2006pattern}. It is known that, if \( \alpha = \beta = \alpha_0 \), this achieves the minimax optimal rate \cite{ bishop2006pattern}.

(ii) Example of fast rate: Classification (exponential convergence) Here, we consider a binary classification problem \( y \in \{\pm 1\} \). We employ the logistic loss function \( \ell(y, f) = \log(1 + \exp(-y f)) \) for \( y \in \{\pm 1\} \) and \( f \in \mathbb{R} \). Corresponding to the loss function, we define the expected loss conditioned by \( X = x \) as \( h(u|x) = E[\ell(Y, u)|X = x] \). Note that \( h(0|x) = \log(2) \). We assume that the strength noise of this binary classification problem is low as follows.

Assumption 3 (Strong low noise condition). Let \( h^*(x) := \inf_{u \in \mathbb{R}} h(u|x) \). Assume that there exists \( \delta > 0 \) such that \( h^*(x) \leq \log(2) - \delta \). Moreover, for any \( \epsilon > 0 \), there exists \( W \in \mathcal{H} \) such that \( \sup_{x \in \text{supp}(P_X)} |h(f_W(x)|x) - h^*(x)| \leq \epsilon \).

The first assumption is satisfied if the label probability is away from the even probability \( 1/2: |P(Y|X = x) - 1/2| \geq \delta \). This condition means that the class label has less noisy than completely random labeling. In that sense, we call this assumption the strong low noise condition, which has been analyzed in \cite{steinwart2001rates,steinwart2012optimal,steinwart2013optimal}. A weaker low noise condition was introduced by \cite{Tsybakov2004} as the low noise condition. The second assumption can be relaxed to the existence of \( W \) only for some \( \epsilon > c_0 \delta \) with sufficiently small \( c_0 \), but we don’t pursue this direction for simplicity.

Assumption 4. Assume \( \mathcal{X}(=\text{supp}(P_X)) \subset [0, 1]^d \), \( P_X \) has density and it is lower bounded as \( p(x) \geq c_0 \) \((\forall x \in \text{supp}(P_X))\) on its support. For \( 2m > d \) and \( m \geq 3 \), the activation function satisfies \( \sigma \in \mathcal{C}^m(\mathbb{R}) \) and \( f^* \) is included in the Sobolev space \( W^m(\mathcal{X}) \) defined on \( \mathcal{X} \).

The following theorem gives an upper-bound of the probability of “perfect classification” for the estimator. More specifically, it shows the error probability converges in an exponential rate.

Theorem 3. Under Assumptions \ref{assumption:3} and \ref{assumption:4}, the convergence in Theorem \ref{theorem:2} holds for \( s = 1 \). Let the convergence rate in the right hand side of Eq. \ref{eq:10} in Theorem \ref{theorem:2} be \( u^* \), and let \( g^*(x) = \text{sign}(P(Y = 1|X = x) - 1/2) \) be the Bayes classifier. If the sample size \( n \) is sufficiently large and \( \lambda \) is appropriately chosen, then the classification error converges exponentially with respect to \( \beta \) and \( k \):

\[
E[\pi_k(\{W_k \in \mathcal{H} | P_X(\text{sign}(f_{W_k}(X)) = g^*(X) \neq 1)\})] \leq \frac{2^m}{\beta^{2m/(2m-d)}} + \exp(-c'\beta^d/2m-d).
\]
The proof is given in Appendix D.3. This theorem states that if we choose the step size $\eta$ sufficiently small, then the error probability converges exponentially as $k$ and $\beta$ increase. Even if the first term of the right hand side is larger than the second term, we can make this as small as the second term by running the algorithm several times and picking up the best one with respect to validation error if $\Xi_k \ll 1$ (see Appendix D.3 for this discussion).

5 Conclusion

In this paper, we have formulated the deep learning training as a transportation map estimation and analyzed its convergence and generalization error through the infinite dimensional Langevin dynamics. Unlike exiting analysis, our formulation can incorporate spatial correlation of noise and achieve global convergence without taking the limit of infinite width. The generalization analysis reveals the dynamics achieves a stable estimator with $O(1/\sqrt{n})$ convergence of generalization error and shows fast learning rate of the excess risk. Finally, we have shown a convergence rate of excess risk for regression and classification. The rate for regression recovers the minimax optimal rate known in Bayesian nonparametrics and that for classification achieves exponential convergence under the strong low noise condition.

Additional notation

For a measurable function \( f : \mathcal{X} \to \mathbb{R} \), we define

\[
\|f\|_\infty := \sup_{x \in \text{supp}(f)} |f(x)|.
\]

A Proof of Proposition [1]

We apply the result [44]. Let \( \{Z_n\}_{n \in \mathbb{N}} \) be a dynamics obeying

\[
Z_{n+1} = S_\eta Z_n + \sqrt{\eta/\beta} S_\eta \xi_n,
\]

with \( Z_0 = 0 \). Let \( k(p) := \sup_{n \geq 0} E(\|Z_n\|^p) \) for \( p > 0 \), then it is known that \( k(p) < \infty \) for any \( p > 0 \). Let \( \{Z_n\}_{n \in \mathbb{N}} \) solve \( Z_0 = 0 \) and with \( \beta > \eta \). Then, we can show that \( k(p) := \sup_{n \geq 0} E(\|Z_n\|^p) < \infty \) (\( \forall p > 0 \)). Using \( k(p) \), we define \( b' = \frac{c_\mu}{\lambda} B + k(1) \). We will show that \( k(1) \leq \frac{c_\mu}{\beta \lambda} \). Then, we can see that \( b' \leq b \). Now, we show \( k(1) \leq \frac{c_\mu}{\beta \lambda} \).

First, note that

\[
Z_n = \sqrt{\frac{\eta}{\beta}} \sum_{\ell=0}^{n-1} S_\eta^{-\ell} \epsilon_\ell.
\]

Therefore, we have

\[
E[\|Z_n\|^2] = \frac{n}{\beta} \sum_{\ell=0}^{n-1} \text{Tr} [S_\eta^2 (n-\ell)] = \frac{n}{\beta} \text{Tr} [(S_\eta^2 - S_\eta^2 (I - S_\eta^2)^{-1})] \leq \frac{n}{\beta} \text{Tr} [S_\eta^2 (I - S_\eta^2)^{-1}] \leq \frac{2}{\beta} \text{Tr} [(S_\eta^2 (I - S_\eta^2)^{-1})]
\]

\[
= \frac{\eta}{\beta} \sum_{k=0}^{\infty} \left( 1 + \eta \lambda / \mu_k \right)^2 \left( 1 - \frac{1}{(1 + \eta \lambda / \mu_k)^2} \right)^{-1} \leq \frac{\eta}{\beta} \sum_{k=0}^{\infty} \frac{1}{(1 + \eta \lambda / \mu_k)^2 - 1} \leq \frac{n}{\beta} \sum_{k=0}^{\infty} \frac{1}{2 \eta \lambda / \mu_k} \leq \frac{1}{2 \eta \lambda} \sum_{k=0}^{\infty} \frac{c_\mu (k+1)^{-2}}{\beta \lambda}.
\]

Then, Jensen’s inequality yields \( k(1) = E[\|Z_n\|_\eta] \leq \sqrt{E[\|Z_n\|^2]} \leq \frac{c_\mu}{\beta \lambda} \).

Let \( \phi : \mathcal{H} \to \mathbb{R} \) be a test function satisfying \( |\phi(\cdot)| \leq V(\cdot) \) and \( \|\phi(x) - \phi(y)\| \leq M\|x-y\| \) \((x, y \in \mathcal{H})\) for \( M > 0 \). Then, [44] showed that there exists a unique invariant measure \( \mu_\eta \) and the following exponential convergence of the expectation of \( \phi \) holds:

\[
|E_{\phi} [\phi(X_n)] - E[\phi(X_{\mu_\eta})]| \leq C_{x_0} \exp(-\Lambda^*_\eta (\kappa + 1)).
\]

where

\[
\Lambda^*_\eta = \min \left( \frac{\lambda}{4 \log((\kappa + 1)/(1-\delta))}, \frac{1}{4 \log((\kappa + 1)/(1-\delta))} \right),
\]

with \( 0 < \delta < 1 \) satisfying \( \delta = \Omega(\exp(-C' \text{poly}(\lambda^{-1}) \beta)) \), \( \beta = \max\{b, 1\} \), \( \kappa = \tilde{b} + 1 \) and \( \tilde{V} = \frac{1}{2 \kappa (2 + \rho^{1/4})} + \frac{1}{\lambda (2 + \rho^{1/4})} \). To show this we note that \( \beta \) in [44] is \( 2 \beta \) using \( \beta \) in this paper. The definition of \( \delta \) is not explicitly shown in [44] (in particular, \( \lambda \) is omitted), but we can recover our definition from the proof. Moreover, [44] assumed that there exists \( \lambda_0, C_{\alpha,2} \in (0, \infty) \) such that

\[
\|\nabla \widehat{L}(W) - \nabla \widehat{L}(W')\|_\mathcal{H} \leq L\|W - W'\|_\mathcal{H} \quad (\forall W, W' \in \mathcal{H}),
\]

16
\[ \|\nabla^2 \hat{L}(W) \cdot (h, k)\| \leq C_{\alpha, 2} \|h\|_\mathcal{H} \|k\|_\alpha \quad (\forall W, h, k \in \mathcal{H}), \]

instead of our assumption \(\|\nabla^2 \hat{L}(W) - \nabla^2 \hat{L}(W')\|_\mathcal{H} \leq L\|W - W'\|_\alpha\). However, we can see that their proof is valid even under our assumption.

Let \(C^2_b\) be a set of functions \(f : \mathcal{H} \rightarrow \mathbb{R}\) that is continuously twice differentiable with bounded derivatives. Under the same setting above, [14] also showed that, for any \(0 < \kappa < 1/2, 0 < \eta_0\), there exists a constant \(C\) such that, if the test function \(\phi\) satisfies \(\phi \in C^2_b\), then for any \(0 < \eta < \eta_0\), it holds that

\[ |E[\phi(X^{\eta})] - E[\phi(X^{\max})]| \leq C \left( \frac{\|\phi\|_0}{\Lambda_0} \epsilon\eta^{1/2-\kappa} \right), \]  

where \(\|\phi\|_0 := \max\{\|\phi\|_\infty, \sup_{x \in \mathcal{H}} \|\nabla \phi(x)\|_\mathcal{H}, \sup_{x \in \mathcal{H}} \|\nabla^2 \phi(x)\|_{B(\mathcal{H})}\}\) for \(\phi \in C^2_b\) where \(\|\cdot\|_{B(\mathcal{H})}\) is the norm as a linear operator.

Thus, if we let \(\phi(\cdot) = \hat{L}(\cdot)/\hat{R}\), then \(\hat{\phi}\) satisfies the assumption with \(M = B/\hat{R}\). Therefore, we obtain that

\[ |E_{\eta}[\hat{L}(X_{\eta})] - E[\hat{L}(X^{\max})]| \leq \hat{R} \left[ C_{\eta} \max(-\Lambda^*_\eta(\eta n - 1)) + C_{\eta} \frac{\|\phi\|_0}{\Lambda_0} \epsilon\eta^{1/2-\kappa} \right]. \]

This gives the assertion.

Finally, we would like to note that since the assumption is satisfied almost surely, \(\mathcal{L}\) also satisfies the assumption instead of \(\hat{\mathcal{L}}\). That means the same convergence rate holds also for \(\phi(W) = \mathcal{L}\).

**B Proof of Theorem 1**

**Proof.** [51] proved that, for any probability measure \(Q\) which is absolutely continuous to \(\pi_\infty\), it holds that

\[ E_{W \sim Q}[\mathcal{L}(W)] \leq E_{W \sim Q}[\hat{\mathcal{L}}(W)] + \frac{1}{\sqrt{n}} KL(Q||\pi_\infty) + \frac{R^2}{\sqrt{n}} \left[ 2 \left( 1 + \frac{2\beta}{\sqrt{n}} \right) + \log \left( \frac{1 + e^{R^2/2}}{\delta} \right) \right], \]  

with probability \(1 - \delta\).

On the other hand, Proposition 1 gives that

\[ |E_{W_k \sim \pi_k}[\mathcal{L}(W_k)] - E_{W \sim \pi_\infty}[\mathcal{L}(W)]| \leq \Xi_k, \]  

\[ |E_{W_k \sim \pi_k}[\hat{\mathcal{L}}(W_k)] - E_{W \sim \pi_\infty}[\hat{\mathcal{L}}(W)]| \leq \Xi_k. \]

Then, by substituting \(Q = \pi_\infty\) into Eq. (13) and applying the two inequalities above, we obtain the assertion. \(\square\)

**C Proof of Lemma 1**

By the definition of \(f_W\), we have

\[
\begin{align*}
    f_W(x) - f_{W'}(x) & \leq \int \left[ (\hat{W}_2(a) - \hat{W}'_2(a))\sigma(\hat{W}_1(w)\top x) + \hat{W}'_2(a)\sigma(\hat{W}_1(w)\top x) - \sigma(\hat{W}'_1(w)\top x) \right] d\rho_0(a, w) \\
    & \leq \sqrt{\int (\hat{W}_2(a) - \hat{W}'_2(a))^2 d\rho_0(a, w)} + \sqrt{\int (\hat{W}'_2(a))^2 (\sigma(\hat{W}_1(w)\top x) - \sigma(\hat{W}'_1(w)\top x))^2 d\rho_0(a, w)} \\
    & \leq \sqrt{\int (\hat{W}_2(a) - \hat{W}'_2(a))^2 d\rho_0(a, w)} + R \sqrt{\int (\sigma(\hat{W}_1(w)\top x) - \sigma(\hat{W}'_1(w)\top x))^2 d\rho_0(a, w)},
\end{align*}
\]

17
where we used $|\sigma(x)| \leq 0$, 1-Lipschitz continuity of the clipping operation and $|\tilde{W}_2(a)| \leq R$. By noticing that $\|x\| \leq D$ and $\sigma$ and the clipping operation $W(w) \mapsto \tilde{W}(w)$ are 1-Lipschitz continuous, the right hand side can be further bounded by

$$\sqrt{\int (W_2(a) - \tilde{W}_2(a))^2 d\rho_0(a, w) + R_1 \int (\tilde{W}_1(w) - \tilde{W}_1'(w))^2 d\rho_0(a, w)}$$

$$\leq \sqrt{\int (W_2(a) - \tilde{W}_2'(a))^2 d\rho_0(a, w) + RD \int \|\tilde{W}_1(w) - W_1'(w)\|^2 d\rho_0(a, w)}$$

$$\leq \sqrt{\int (W_2(a) - \tilde{W}_2'(a))^2 d\rho_0(a, w) + RD \int \|\tilde{W}_1(w) - W_1'(w)\|^2 d\rho_0(a, w)}$$

$$\leq (1 + RD) \sqrt{\int (W_2(a) - \tilde{W}_2'(a))^2 + \|W_1(w) - W_1'(w)\|^2 d\rho_0(a, w)} = (1 + RD) \|W - W'\|_{L^2(\rho_0)}.$$ 

This gives the assertion.

**D Proof of fast rate of excess risk bounds**

**D.1 Gaussian correlation inequality**

**Lemma 2** (Gaussian correlation inequality). Let $\tilde{\mathcal{H}}$ be a separable Hilbert space equipped with the complete orthonormal system $(e_i)_{i=1}^\infty$, and suppose that $\nu$ is a Gaussian measure in $\tilde{\mathcal{H}}$ with mean 0 and covariance $\Sigma = \text{diag}(\mu_1, \mu_2, \ldots)$ with respect to CONS $(e_i)_i$, where $\sum_{i=1}^n \mu_i^2 < \infty$, that is, $\nu$ is the distribution corresponding to $\sum_{i=1}^\infty \varepsilon_i \sqrt{\mu_i} e_i$ for $\varepsilon_i \sim N(0,1)$ (i.i.d.). Let $A^1 = \{\sum_{i=1}^\infty \alpha_i e_i \in \tilde{\mathcal{H}} \mid \sum_{i=1}^\infty \alpha_i^2 \leq 1, \alpha_i \in \mathbb{R}\}$ for $a_i \geq 0$ ($i = 1, 2, \ldots$) and $A^2 = \{\sum_{i=1}^\infty \alpha_i e_i \in \tilde{\mathcal{H}} \mid \sum_{i=1}^\infty b_i \alpha_i^2 \leq 1, \alpha_i \in \mathbb{R}\}$ for $b_i \geq 0$ ($i = 1, 2, \ldots$). Then, we have

$$\nu(A^1 \cap A^2) \geq \nu(A^1)\nu(A^2).$$

**Proof.** Let $A^1_n$ and $A^2_n$ be the cylinder set that “truncates” $A^1$ an $A^2$ up to index $n$: $A^1_n = \{\sum_{i=1}^\infty \alpha_i e_i \in \tilde{\mathcal{H}} \mid \sum_{i=1}^n \alpha_i^2 < 1\}$ and $A^2_n = \{\sum_{i=1}^\infty \alpha_i e_i \in \tilde{\mathcal{H}} \mid \sum_{i=1}^n b_i \alpha_i^2 \leq 1\}$. By the Gaussian correlation inequality $\mathbb{E} \mathbb{E}^2$, it holds that

$$\nu(A^1_n \cap A^2_n) \geq \nu(A^1_n)\nu(A^2_n).$$

Note that we can apply the Gaussian correlation inequality for a finite dimensional Gaussian measure. Next, we extend this inequality to the infinite dimensional space. Since $(A^1_n)_n$ is a monotonically decreasing sequence, i.e., $A^1_1 \subset A^1_2 \subset \cdots \subset A^1_n$ for $m < n$, and $\cap_{n=1}^\infty A^1_n = A^1$, the continuity of probability measure gives that $\lim_{n \to \infty} \nu(A^1_n) = \nu(A^1)$. Similarly, it holds that $\lim_{n \to \infty} \nu(A^2_n) = \nu(A^2)$.

Since $A^2 \subset A^1_1$ and $A^2_n \subset A^1_n$, it holds that $\nu(A^1 \cap A^2) \leq \nu(A^1 \cap A^2_n)$. On the other hand, we also have

$$\nu(A^1_n \cap A^2_n) = \nu((A^1_n \cap A^2_n) \cap (A^2 \cap A^2_n))$$

$$\leq \nu((A^1 \cap A^2) \cup (A^1_n \setminus A^1) \cup (A^2_n \setminus A^2))$$

$$\leq \nu(A^1 \cap A^2) + \nu(A^1_n \setminus A^1) + \nu(A^2_n \setminus A^2)$$

$$\to \nu(A^1 \cap A^2).$$
Therefore, we have that
\[
\lim_{n \to \infty} \nu(A_n^1 \cap A_n^2) = \nu(A^1 \cap A^2).
\]
Combining all these arguments, we finally have that
\[
\nu(A^1 \cap A^2) \geq \nu(A^1)\nu(A^2).
\]

D.2 Proof of general excess risk bound (Theorem 2)

Proof. Since \(\sigma\) and \(\ell(y, \cdot)\) are in \(C^3(\mathbb{R})\) and \(\gamma > 1/2\), we can easily verify that the empirical risk satisfies Assumption I by noticing the clipping operation in the model.

For \(0 < \theta < 1\), let \(\mathcal{H}_{\tilde{K}} := \mathcal{H}_{\tilde{K}^{(\gamma+1)}}\). It is known that if the natural inclusion \(I_{\tilde{K}, \tilde{K}^*} : \mathcal{H}_{\tilde{K}} \to \mathcal{H}_{\tilde{K}^*}\) is Hilbert-Schmidt, then the sample path of \(\tilde{V}_{\beta}\) is included in \(\mathcal{H}_{\tilde{K}^*}\) probability 1 (Theorem 5.2 of [60]). In our case, since \(\mu_\delta \lesssim 1/k^2\), the eigenvalues \(\mu_k(\tilde{K})\) of \(\tilde{K}\) satisfies \(\mu_k(\tilde{K}) \lesssim 1/k^{2(\gamma+1)}\). Theorem 5.2 of [60] also states that \(I_{\tilde{K}, \tilde{K}^*}\) is Hilbert-Schmidt if and only if \(\sum_{k=1}^{\infty} \mu_k(\tilde{K})^{1-\theta} < \infty\). Therefore, by setting \(\tilde{\alpha} := 1/(2(\gamma + 1))\), \(\theta < 1 - \tilde{\alpha}\) is sufficient for this property. From now on, we assume that \(\theta < 1 - \tilde{\alpha}\). For notational simplicity, let \(\lambda_\beta := \lambda_\beta^\tilde{\alpha}\).

\[
E_{W \sim \varphi}[\|T_{\tilde{K}}^{\theta/2}W\|^2_{\mathcal{H}_{\tilde{K}^*}}] = \text{Tr}[T_{\tilde{K}}^{\gamma/2}(\lambda_\beta^{-1}T_{\tilde{K}})T_{\tilde{K}}^{\gamma/2}T_{\tilde{K}}^{-\theta(\gamma+1)}] = \lambda_\beta^{-1} \text{Tr}[T_{\tilde{K}}^{\gamma(\gamma+1)(\theta-1)}]
\]

Therefore, we obtain that, for \(\tilde{R}_\theta > 0\),
\[
\tilde{\nu}_\beta(\{h \in \mathcal{H} \mid \|h\|_{\mathcal{H}_{\tilde{K}^*}} \geq \lambda_\beta^{-1/2}\tilde{R}_\theta\}) \leq \frac{E_{W \sim \varphi}[\|T_{\tilde{K}}^{\theta/2}W\|^2_{\mathcal{H}_{\tilde{K}^*}}]}{\lambda_\beta^{-1}\tilde{R}_\theta} \leq \frac{\text{Tr}[T_{\tilde{K}}^{\gamma(\gamma+1)(\theta-1)}]}{\tilde{R}_\theta}.
\]

Hence, by setting \(\tilde{R}_\theta = 2\text{Tr}[T_{\tilde{K}}^{\gamma(\gamma+1)(\theta-1)}]\), we can guarantee that \(\tilde{\nu}_\beta(\{h \in \mathcal{H} \mid \|h\|_{\mathcal{H}_{\tilde{K}^*}} \leq \lambda_\beta^{-1/2}\tilde{R}_\theta\}) \geq 1/2\).

Let \(B_\varepsilon = (\varepsilon \mathcal{B}_{\mathcal{H}}) \cap (\lambda_\beta^{-1/2}\tilde{R}_\theta \mathcal{B}_{\mathcal{H}_{\tilde{K}^*}})\). We define
\[
\phi_{\beta,\lambda}^{(0)}(\varepsilon) := -\log \tilde{\nu}_\beta(\{W \in \mathcal{H} \mid W \in B_\varepsilon\}).
\]

For any \(\delta > 0\), pick up \(h^*\) such
\[
\lambda_\beta\|h^*\|_{\mathcal{H}_{\tilde{K}}}^2 \leq (1 + \delta) \inf_{h \in \mathcal{H}_{\tilde{K}} : \mathcal{L}(h) - \mathcal{L}(f^*) \leq \varepsilon^2} \lambda_\beta\|h\|_{\mathcal{H}_{\tilde{K}}}^2
\]
\[
\mathcal{L}(h^*) - \mathcal{L}(f^*) \leq \varepsilon^2.
\]

Then, by Borel’s inequality, it holds that
\[
-\log \tilde{\nu}_\beta(\{h \in \mathcal{H} : \|h - h^*\|_{\mathcal{H}} \leq \varepsilon\}) \leq (1 + \delta)\phi_{\beta,\lambda}(\varepsilon).
\]

\(L\) is the smoothness of the loss function and with respect to \(W\)
\[
\mathcal{L}(f^*) + (f_{h^*} - f^*, \nabla \mathcal{L}(f^*))_{L_2} + \frac{1}{2L}\|\nabla \mathcal{L}(f_{h^*}) - \nabla \mathcal{L}(f^*)\|_{L_2}^2 \leq \mathcal{L}(f_{h^*})
\]
Thus,
\[
\|\nabla \mathcal{L}(f_{h^*})\|_{L_2}^2 \leq 2L\mathcal{L}(h^*) \leq 2L\varepsilon^2.
\]
Therefore, for any $h$ such that $\|h - h^*\|_H \leq \epsilon$ satisfies

$$L(h) \leq L(f_h) + \langle f_h - f_h^*, \nabla L(f_h^*) \rangle_{L_2} + \frac{L}{2} \|f_h - f_h^*\|_2^2$$

$$\leq L(f_h^*) + \frac{1}{2} \|f_h - f_h^*\|_2^2 + \frac{1}{2} \|\nabla L(f_h^*)\|_2^2 + \frac{L}{2} \|f_h - f_h^*\|_2^2$$

$$\leq L(f_h^*) + \frac{1}{2} \|f_h - f_h^*\|_2^2 + \frac{1}{2} 2Lc^2 + \frac{L}{2} \|f_h - f_h^*\|_2^2$$

$$\leq \epsilon^2 + \frac{1 + L}{2} (1 + RD)^2 \|h - h^*\|_H^2 + Lc^2$$

$$\leq \left(1 + \frac{(1 + L)(1 + RD)^2}{2} + L \right) \epsilon^2 =: \phi(L,R,D)\epsilon^2.$$ This yields that

$$- \log \tilde{v}_\beta(\{h \in H : L(h) - L(f^*) \leq C(L,R,D)\epsilon^2\})$$

$$\leq - \log \tilde{v}_\beta(\{h \in H : L(h) - L(f^*) \leq C(L,R,D)\epsilon^2, \|h - h^*\|_H \leq \epsilon\})$$

$$\leq (1 + \delta) \phi(\beta,\lambda)(\epsilon).$$

Since $\delta$ is arbitrary, we obtain that

$$- \log \tilde{v}_\beta(\{h \in H : L(h) - L(f^*) \leq C(L,R,D)\epsilon^2\}) \leq \phi(\beta,\lambda)(\epsilon).$$

(14)

By the Gaussian correlation inequality (Lemma 2), we have that

$$\phi^{(0)}(\epsilon) = - \log \tilde{v}_\beta(\{W \in H : W \in B_\epsilon\})$$

$$\leq - \log \tilde{v}_\beta(\{h \in H : \|h\|_H \leq \epsilon\}) \times \tilde{v}_\beta(\{h \in H : \|h\|_{H_{K^0}} \leq \lambda^{-1/2} \tilde{R}_0\})$$

$$\leq - \log \tilde{v}_\beta(\{h \in H : \|h\|_H \leq \epsilon\}) \times 1/2$$

$$= - \log \tilde{v}_\beta(\{h \in H : \|h\|_H \leq \epsilon\}) + \log(2).$$

Therefore, we can see that

$$\inf_{h \in H : L(h) - L(f^*) \leq \epsilon^2/2} \lambda_\beta \|h\|_{H_K}^2 + \phi^{(0)}(\epsilon) \leq \phi(\beta,\lambda)(\epsilon).$$

Here we define $\epsilon^*$ as

$$\epsilon^* := \max\{\inf\{\epsilon > 0 : \phi(\beta,\lambda)(\epsilon) \leq \beta\epsilon^2\}, n^{-\frac{1}{1-2\beta}}\}.$$ 

Let $r > 1$, and $M_r := -2\Phi^{-1}(e^{-\beta\epsilon^2 r})$ where $\Phi$ is the cumulative distribution function of the standard normal distribution. Since $\Phi^{-1}(y) \geq -\sqrt{5/2} \log(1/y)$ for every $y \in (0,1)$, $M_r$ is bounded by

$$-M_r/2 \geq -\sqrt{5/2} \log(e^{\beta\epsilon^2 r}) = -\sqrt{5/2} \beta\epsilon^2 r \Rightarrow M_r \leq \sqrt{5/2} \beta\epsilon^2 r$$

if $e^{-\beta\epsilon^2 r} \leq 1/2$. Let

$$\mathcal{F}_r := B_{\epsilon^*} + M_r \lambda^{-1/2} \mathcal{B}_{H_K}.$$ 

By Borell’s inequality (Theorem 3.1 of [10]), the prior probability mass of $\mathcal{F}_r$ is lower bounded by

$$\tilde{v}_\beta(\mathcal{F}_r) \geq \Phi(M_r + \alpha_r).$$

20
where \( \alpha_r \in \mathbb{R} \) is determined by

\[
\Phi(\alpha_r) = \tilde{\nu}_\beta(B_{\alpha_r}) = e^{-\phi_{\beta,\lambda}(\alpha_r)}.
\]

Since \( \phi_{\beta,\lambda}^{(0)}(\epsilon^*) \leq \phi_{\beta,\lambda}(\epsilon^*) + \log(2) \leq \beta \epsilon^* \leq \beta \epsilon^* r \), we have \( \Phi(\alpha_r) \geq e^{-\beta \epsilon^* r} \) which implies

\[
\alpha_r \geq -\frac{1}{2} M_r.
\]

Therefore,

\[
\tilde{\nu}_\beta(F_r) \geq \Phi(M_r + \alpha_r) \geq \Phi(M_r/2) \geq 1 - \exp(-\beta \epsilon^* r).
\]

By the proof of Theorem 2.1 in \cite{71}, we obtain that the metric entropy of \( F_r \) is bounded by

\[
\log N(F_r, \epsilon^*, \| \cdot \|_H) \leq \frac{1}{2} M_r^2 + \phi_{\beta,\lambda}^{(0)}(\epsilon^*),
\]

and, more strongly, there exist \( h_1, \ldots, h_{N_r} \in F_r \) for \( N_r := \mathcal{N}(F_r, \epsilon^*, \| \cdot \|_H) \) such that

\[
F_r \subset B_r + \{ h_1, \ldots, h_{N_r} \}.
\]

This indicates that, even for smaller \( \epsilon' \leq \epsilon^* \), it holds that

\[
\log N(F_r, \epsilon', \| \cdot \|_H) \leq N_r + \log N(B_r, \epsilon', \| \cdot \|_H).
\]

Then, if we let \( \tilde{\phi}(\epsilon') = \log N((\lambda_{\beta}^{-1/2} \tilde{R}_\theta)B_{H_{\epsilon'}} \epsilon', \| \cdot \|_H) \), then it holds that

\[
\log N(F_r, \epsilon', \| \cdot \|_H) \leq N_r + \tilde{\bar{\phi}}(\epsilon') \leq \frac{1}{2} M_r^2 + \phi_{\beta,\lambda}^{(0)}(\epsilon^*) + \tilde{\phi}(\epsilon') \leq (5r + 1)\beta \epsilon^* + \tilde{\bar{\phi}}(\epsilon').
\]

(15)

Note that if \( \epsilon' > \epsilon \), then by using the fact \( N_{\epsilon'} \leq N_{\epsilon} \), we can see that this inequality still holds:

\[
\log N(F_r, \epsilon', \| \cdot \|_H) = N_{\epsilon'} \leq N_{\epsilon} \leq N_r + \tilde{\bar{\phi}}(\epsilon').
\]

The covering number of \( B_{H_{\epsilon'}} \) can be evaluated using the decay rate of the spectrum \( (\mu_k(\tilde{R}_\theta))_k \) \cite{62}. Indeed, \( \mu_k(\tilde{R}_\theta) \leq k^{-\beta} \) implies \( \tilde{\phi}(\epsilon') \leq (\epsilon'/\lambda_{\beta}^{1/2})^{-2\beta} \)

Theorem 15]. Moreover, the small ball probability \( \phi_{\beta,\lambda}^{(0)}(\epsilon) \) can be evaluated using the covering number. First notice that \( \phi_{\beta,\lambda}^{(0)}(\epsilon) = - \log \tilde{\nu}_\beta(\{ W \in H \mid W \in B_r \}) \leq - \log \tilde{\nu}_\beta(\{ W \in H \mid \| W \|_H \leq \epsilon \}) =: \varphi(\epsilon) \), and then \cite{21} showed that

\[
\varphi(2\epsilon) \leq \log N \left( \frac{\epsilon}{\sqrt{2\varphi(\epsilon)}}, \lambda_{\beta}^{-1/2} B_{H_{\epsilon}}, \| \cdot \|_H \right) \lesssim \varphi(\epsilon).
\]

Here, since the entropy number in the middle is evaluated as \( \log N \left( \epsilon, \lambda_{\beta}^{-1/2} B_{H_{\epsilon}}, \| \cdot \|_H \right) \lesssim (\epsilon/\lambda_{\beta}^{1/2})^{-2\beta} \), we obtain

\[
\phi_{\beta,\lambda}^{(0)}(\epsilon) \leq \varphi(\epsilon) \lesssim \left( \frac{\epsilon}{\lambda_{\beta}^{1/2}} \right)^{-2\beta}.
\]

(16)

In this setting, we will show that, for any \( r > 1 \), there exists an event \( \mathcal{E} \) with respect to data generation \( D_n \) and exists \( u^* > 0 \) such that

\[
A : P(\mathcal{E}) \leq 2e^{-c' \epsilon \min\{ \beta_\epsilon^2, \epsilon_\epsilon^* (2 - \epsilon) \} r} \quad \text{for a constant } c' > 0,
\]

\[
B : \tilde{\mathcal{L}}(W) - \mathcal{L}(f^*) \geq \frac{1}{2} \| (\mathcal{L}(h) - \mathcal{L}(f^*)) - u^* r \| \quad (\forall h \in F_r)
\]

21
under the event $\mathcal{E}$,

$$C : \mathbb{E}[\pi_\infty (\mathcal{F}_r) 1_{\mathcal{E}}] \leq 2 \exp \left[-\frac{1}{2} (r-2) \beta \epsilon^2 \right],$$

$$D : \mathbb{E}[\pi_\infty (\{W \in \mathcal{F}_r : \mathcal{L}(W) - \mathcal{L}(f^*) \geq 3ru^*\}) 1_{\mathcal{E}}] \leq \exp \left[-\frac{1}{2} (r-2) \beta \epsilon^2 \right].$$

From now on, we will define $u^*$ and $\mathcal{E}$ and derive bound for each $A, B, C, D$ one by one.

**Step 1: Bound of $u^*$ and $\mathcal{E}$**

By Talagrand’s concentration inequality [66, 12], we have

$$P \left( \sup_{h \in \mathcal{F}_r} \frac{|\mathcal{L}(h) - \mathcal{L}(f^*) - \hat{\mathcal{L}}(h) - \hat{\mathcal{L}}(f^*)|}{\mathcal{L}(h) - \mathcal{L}(f^*) + u} \right) \geq 2\mathbb{E} \left[ \sup_{h \in \mathcal{F}_r} \frac{|\mathcal{L}(h) - \mathcal{L}(f^*) - \hat{\mathcal{L}}(h) - \hat{\mathcal{L}}(f^*)|}{\mathcal{L}(h) - \mathcal{L}(f^*) + u} \right] + \sqrt{\frac{2t}{n} V + \frac{2tU}{n}} \leq \exp(-t),$$

for any $t \geq 1$, where

$$V = \sup_{h \in \mathcal{F}_r} \frac{\mathbb{E}[\|\ell(h, Z) - \ell(f^*, Z) - \mathbb{E}[\ell(h, Z) - \ell(f^*, Z)]\|^2]}{(\hat{\mathcal{L}}(h) - \mathcal{L}(f^*) + u)^2}$$

and

$$U = \sup_{h \in \mathcal{F}_r} \frac{\|\ell(h, \cdot) - \ell(f^*, \cdot) - \mathbb{E}[\ell(h, Z) - \ell(f^*, Z)]\|_\infty}{\mathcal{L}(h) - \mathcal{L}(f^*) + u}.$$

By the boundedness assumption of the loss function, we can see that

$$U \leq \frac{\bar{R}}{u}.$$

Moreover, by the Bernstein condition, it holds that

$$\text{Var}[\ell(f_h, Z) - \ell(f^*, Z)] \leq \mathbb{E}[\|\ell(f_h, Z) - \ell(f^*, Z)\|^2] \leq C_B (\mathcal{L}(h) - \mathcal{L}(f^*))^s,$$

which gives

$$V \leq C_B \sup_{h \in \mathcal{F}_r} \frac{(\mathcal{L}(h) - \mathcal{L}(f^*))^s}{(\mathcal{L}(h) - \mathcal{L}(f^*) + u)^2} \leq \frac{C_B}{u^{2-s}}.$$

Therefore, we have that

$$P \left( \sup_{h \in \mathcal{F}_r} \frac{|\mathcal{L}(h) - \mathcal{L}(f^*) - \hat{\mathcal{L}}(h) - \hat{\mathcal{L}}(f^*)|}{\mathcal{L}(h) - \mathcal{L}(f^*) + u} \right) \geq 2\mathbb{E} \left[ \sup_{h \in \mathcal{F}_r} \frac{|\mathcal{L}(h) - \mathcal{L}(f^*) - \hat{\mathcal{L}}(h) - \hat{\mathcal{L}}(f^*)|}{\mathcal{L}(h) - \mathcal{L}(f^*) + u} \right] + \sqrt{\frac{2B}{nu^{2-s} t} + \frac{2\bar{R} t}{nu}} \leq \exp(-t),$$

for any $t \geq 1$.

Hereafter, we bound the expectation of the supremum of the ratio type empirical process:

$$\mathbb{E} \left[ \sup_{h \in \mathcal{F}_r} \frac{|\mathcal{L}(h) - \mathcal{L}(f^*) - \hat{\mathcal{L}}(h) - \hat{\mathcal{L}}(f^*)|}{\mathcal{L}(h) - \mathcal{L}(f^*) + u} \right].$$

Let the empirical $L_2$-norm be $\|h\|_n := \sqrt{\frac{1}{n} \sum_{i=1}^{n} h(z_i)^2}$. By
the usual Rademacher complexity and covering number argument (Lemma 11.4 of [11], Theorem 5.22 of [74] and Lemma A.5 of [6] for example), the non-ratio-type empirical process can be bounded as

\[
E \left[ \sup_{h \in F_r \cap L(h) - L(f^*) - \hat{L}(h) - \hat{L}(f^*)} \right] \\
\leq 2E \left[ \sup_{h \in F_r \cap L(h) - L(f^*)} \left\{ \frac{1}{n} \sum_{i=1}^{n} \epsilon_i \left( \ell(f_h, z_i) - \ell(f^*, z_i) - (L(h) - L(f^*)) \right) \right\} \right] \\
\leq CE \left[ \inf_{a > 0} \left\{ a + \int_{a}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ \ell(h, \cdot) - \ell(f^*, \cdot) \mid h \in F_r, L(h) - L(f^*) \leq u \}, \| \cdot \|_{n'})} \right\} \right],
\]

where \( \hat{r}(u) := \sup\{ \| \ell(f_h, \cdot) - \ell(f^*, \cdot) \|_n^2 \mid h \in F_r, L(h) - L(f^*) \leq u \} \) and \( C \) is a universal constant. The Dudley integral in the right hand side can be bounded by

\[
\int_{a}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ \ell(h, \cdot) - \ell(f^*, \cdot) \mid h \in F_r, L(h) - L(f^*) \leq u \}, \| \cdot \|_{n'})} \right\} \right] \leq \int_{a}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} d\epsilon'} \right\} \right] \leq \int_{a}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} d\epsilon'} \right\} \right] \leq \int_{a}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} d\epsilon'} \right\} \right]
\]

where we used Lemma [11] to show (1), and (2) is shown by Eq. [15]. If we let \( a = 1/n \), then we have

\[
E \left[ \sup_{h \in F_r \cap L(h) - L(f^*)} \frac{\| \ell(h, \cdot) - \ell(f^*, \cdot) \|_n^2}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} \right] \leq C \left[ \frac{1}{n} + \int_{1/n}^{\hat{r}(u)} \sqrt{\frac{n}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} d\epsilon'} \right] :=: \psi_{r,e^*}(u).
\]

Here, we assume that \( \psi_{r,e^*}(u) \) satisfies \( \psi_{r,e^*}(2u) \leq 2\psi_{r,e^*}(u) \) for \( u > 0 \), then the so called peeling device gives

\[
E \left[ \sup_{h \in F_r} \frac{\| \ell(h, \cdot) - \ell(f^*, \cdot) \|_n^2}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} \right] \leq \frac{4\psi_{r,e^*}(u)}{u}.
\]

(Theorem 7.7 and Eq. (7.17) of [61]). Therefore, Eq. [17] can yields that

\[
P \left( \sup_{h \in F_r} \frac{\| \ell(h, \cdot) - \ell(f^*, \cdot) \|_n^2}{\log N(\{ f_h \mid h \in F_r \}, \| \cdot \|_{n'})} \geq 8\frac{\psi_{r,e^*}(u)}{u} + \sqrt{\frac{2C_B}{nu^{2-s}}t + \frac{2R}{nt}} \right) \leq \exp(-t).
\]

Here, for \( t_1 = \beta e^2 \), set \( u^* \) as

\[
u^* := \max \left\{ e^2, \inf \left\{ u > 0 : 8\frac{\psi_1(e^2)(u)}{u} + \sqrt{\frac{2C_B}{nu^{2-s}}t_1} + \frac{2R}{nt} \leq 1/2 \right\} \right\}.
\]

Then for more general \( t = t_1r = \beta e^2r \), it holds that

\[
\hat{L}(h) - \hat{L}(f^*) \geq \frac{1}{2}[\| \ell(h, \cdot) - \ell(f^*, \cdot) \|_n^2] - u^*r^2
\]

23
uniformly over all \( h \in \mathcal{F}_r \) with probability \( 1 - e^{-\beta \epsilon^2 r} \). We denote this event by \( \mathcal{E}_1 \).

Eq. (14) gives that

\[-\log \hat{\nu}_\beta(\{ h \in \mathcal{H} : \mathcal{L}(h) - \mathcal{L}(f^*) \leq C_{(L,R,D)} \epsilon^{*2} \}) \leq \phi_{\beta, \lambda}(\epsilon^*).\]

Let the conditional probability measure of \( \hat{\nu}_\beta \) conditioned on the set \( A_{\epsilon^*} := \{ h \in \mathcal{H} : \mathcal{L}(h) - \mathcal{L}(f^*) \leq C_{(L,R,D)} \epsilon^{*2} \} \) be

\[\hat{\nu}_\beta(B|A_{\epsilon^*}) := \frac{\hat{\nu}_\beta(B \cap A_{\epsilon^*})}{\hat{\nu}_\beta(A_{\epsilon^*})},\]

for a measurable set \( B \subset \mathcal{H} \). Let \( \tilde{\ell}(Z) := \int \ell(h, Z) \hat{\nu}_\beta(dh|A_{\epsilon^*}) \). Then, we have that

\[
\int \exp \left( -\beta(\mathcal{L}(h) - \mathcal{L}(f^*)) \right) d\hat{\nu}_\beta(h|A_{\epsilon^*}) \\
\geq \exp \left( -\int \beta(\mathcal{L}(h) - \mathcal{L}(f^*)) d\hat{\nu}_\beta(h|A_{\epsilon^*}) \right) \\
= \exp \left[ -\beta \left( \frac{1}{n} \sum_{i=1}^{n} \tilde{\ell}(z_i) - \mathbb{E}[\tilde{\ell}(Z)] \right) \right].
\]

Now, by the Bernstein’s inequality,

\[
P \left( \frac{1}{n} \sum_{i=1}^{n} \tilde{\ell}(z_i) - \mathbb{E}[\tilde{\ell}(Z)] \geq \sqrt{\frac{2C_B(C_{(L,R,D)} \epsilon^*)^2 t}{n}} + \frac{\tilde{R}t}{n} \right) \leq e^{-t},
\]

for \( t \geq 0 \). Here, let \( t = \frac{1}{8} \min \{ \frac{1}{2C_B(C_{(L,R,D)} \epsilon^*)}, \frac{1}{8} \} ne^{s(2-s)} r \), then it holds that

\[
P \left( \frac{1}{n} \sum_{i=1}^{n} \tilde{\ell}(z_i) - \mathbb{E}[\tilde{\ell}(Z)] \geq \frac{1}{2} \epsilon^2 r \right) \leq e^{-\frac{1}{8} \min \{ \frac{1}{2C_B(C_{(L,R,D)} \epsilon^*)}, \frac{1}{8} \} ne^{s(2-s)} r },
\]

under a condition of \( \epsilon^* \leq 1 \). Therefore, this and the definition of \( \hat{\nu}_\beta(\cdot|A_{\epsilon^*}) \) give that

\[
\int \exp \left( -\beta(\mathcal{L}(h) - \mathcal{L}(f^*)) \right) d\hat{\nu}_\beta(h) \geq \exp \left( -\frac{1}{2} \beta \epsilon^2 r \right) \hat{\nu}_\beta(A_{\epsilon^*}) \\
\geq \exp \left( -\frac{1}{2} \beta \epsilon^2 r - \beta \epsilon^2 \right) \\
\geq \exp \left( -(\frac{\epsilon}{2} + 1) \beta \epsilon^2 \right).
\]

with probability \( 1 - \exp[-\frac{1}{8} \min \{ \frac{1}{2C_B(C_{(L,R,D)} \epsilon^*)}, \frac{1}{8} \} ne^{s(2-s)} r ] \). We define this event as \( \mathcal{E}_2 \).

Combining \( \mathcal{E}_1 \) and \( \mathcal{E}_2 \), we define \( \mathcal{E} = \mathcal{E}_1 \cap \mathcal{E}_2 \), then \( P(\mathcal{E}) \geq 1 - e^{-\beta \epsilon^2 r} - e^{-\frac{1}{8} \min \{ \frac{1}{2C_B(C_{(L,R,D)} \epsilon^*)}, \frac{1}{8} \} ne^{s(2-s)} r } \geq 1 - 2e^{-c' \min \{ \beta \epsilon^2, ne^{s(2-s)} r \} } \) for a constant \( c' > 0 \).

\textbf{Step 2: Bound of } C \textbf{.}

Next, we evaluate the term \( C \).

\[
\mathbb{E}[\pi_\infty(\mathcal{F}_r^c)1_{\mathcal{E}}] \leq \mathbb{E} \left[ 1_{\mathcal{E}} \exp \left( (\frac{\epsilon}{2} + 1) \beta \epsilon^2 \right) \int_{h \in \mathcal{F}_r^c} \exp(-\beta(\mathcal{L}(h) - \mathcal{L}(f^*))) d\hat{\nu}_\beta(h) \right] \\
\leq \exp \left( (\frac{\epsilon}{2} + 1) \beta \epsilon^2 \right) \int_{h \in \mathcal{F}_r^c} \mathbb{E}[\exp(-\beta(\mathcal{L}(h) - \mathcal{L}(f^*)))] d\hat{\nu}_\beta(h)
\]

24
Step 3: Bound of $D$.

Next, we evaluate the term $D$. Based on the arguments above, our goal is reduced to evaluating $u^*$.

Step 4: Integrating all bounds of $A, B, C, D$.

Finally, we integrate all bounds to obtain an excess risk bound.

\[
E_{D^*} \left[ \int \mathcal{L}(W) - \mathcal{L}(f^*) d\pi_{\infty}(W) \right] = E_{D^*} \left[ \int_{0}^{\infty} \pi_{\infty} \left\{ \| W \in \mathcal{H} : \mathcal{L}(W) - \mathcal{L}(f^*) > t \right\} dt \right] = \int_{0}^{\infty} E_{D^*} \left\{ \pi_{\infty} \left\{ \| W \in \mathcal{H} : \mathcal{L}(W) - \mathcal{L}(f^*) > t \right\} \right\} dt \quad \text{(by Fubini's theorem)}
\]

\[
= 3u^* + \int_{1}^{\infty} 3u^* E_{D^*} \left\{ \pi_{\infty} \left\{ \| W \in \mathcal{H} : \mathcal{L}(W) - \mathcal{L}(f^*) > 3ru^* \right\} \right\} dr 
\leq 3u^* + 3u^* \int_{1}^{\infty} \min \{ A + B + C + D, 1 \} dr 
\leq 3u^* + 3u^* \int_{1}^{\infty} \min \left\{ \exp \left( -\frac{1}{2} (r - 2) \beta \epsilon^2 \right) + 2e^{-c' \min \{ \beta \epsilon^2, \beta^2 (2 - \epsilon) \} r}, 1 \right\} dr 
\leq u^*.
\]  

Step 5: Evaluation of $u^*$.

Based on the arguments above, our goal is reduced to evaluating $u^*$. We note that

\[
E[\hat{r}(u)^2] \leq u^* + \hat{R} \psi_{r,\epsilon^2}(u) \leq u^* + \hat{R} E \left[ \int_{0}^{\hat{r}(u)} \sqrt{\frac{\beta \epsilon^2 + \left( \epsilon'/\lambda_d^{1/2} \right)^{-25/\theta}}{n}} dt' \right] 
\]

\[
= u^* + \sqrt{\frac{\beta \epsilon^2}{n}} E[\hat{r}(u)] + \frac{1}{\sqrt{n}} \lambda_d^{\theta/5} E[(\hat{r}(u))^{1-\theta/5}]
\]
\[ \leq u^* + \sqrt{\frac{\beta e^2}{n} \mathbb{E}[\hat{r}(u)]} + \frac{1}{\sqrt{n}} \lambda_{\beta}^{\tilde{\alpha}/\theta} (\mathbb{E}[\hat{r}(u)^2])^{(1-\tilde{\alpha}/\theta)/2}. \]

Therefore, we have that
\[ \mathbb{E}[\hat{r}(u)^2] \lesssim u^* \sqrt{\frac{\beta e^2}{n} r} \vee n \frac{1}{\sqrt{n}} \lambda_{\beta}^{2\tilde{\alpha}/\theta}. \]

This gives that
\[ \psi_{\tau, \epsilon^*}(u) \lesssim \mathbb{E} \left[ \int_0^{\hat{r}(u)} \sqrt{\frac{\beta e^2}{n} \mathbb{E}[\hat{r}(u)^2]} + \frac{1}{\sqrt{n}} \lambda_{\beta}^{\tilde{\alpha}/\theta} (\mathbb{E}[\hat{r}(u)^2])^{(1-\tilde{\alpha}/\theta)/2} \right] \]
\[ \lesssim \sqrt{\frac{\beta e^2}{n} \mathbb{E}[\hat{r}(u)^2]} + \frac{1}{\sqrt{n}} \lambda_{\beta}^{\tilde{\alpha}/\theta} \left( \mathbb{E}[\hat{r}(u)^2] \right)^{(1-\tilde{\alpha}/\theta)/2} \]
\[ \lesssim \frac{\beta e^2}{n} u^* + n \frac{1}{\sqrt{n}} \lambda_{\beta}^{2\tilde{\alpha}/\theta} + u^*/\sqrt{n} \frac{1}{\sqrt{n}} \lambda_{\beta}^{2\tilde{\alpha}/\theta} \text{ (ifer Young’s inequality).} \]

Therefore, by the definition of \( u^* \), we obtain that
\[ u^* \lesssim \epsilon^* \sqrt{\frac{\beta e^2}{n} + n \frac{1}{\sqrt{n}} \lambda_{\beta}^{2\tilde{\alpha}/\theta}} \]
\[ \lesssim \frac{1}{\sqrt{n}} \]

This yields the assertion. \( \square \)

### D.3 Proof of fast rate for classification (Theorem 3)

**Proof.** Since both \( \hat{W}_2(a) \) and \( \hat{W}_1(w) \) are bounded and the activation function \( \sigma \) is included in the Hölder class \( C^m(\mathbb{R}) \), the model \( \{f_W \mid W \in \mathcal{H}\} \) is also included in the Hölder class \( C^m(\mathcal{X}) \) with regularity \( m \) and especially it is included in the Sobolev space \( W^m(\mathcal{X}) \):
\[ f_W \in W^m(\mathcal{X}). \]

Moreover, since the logistic loss is \( C^\infty \)-class and its derivative up to \( m \)-th order is upper bounded, the function \( x \mapsto \ell(f_W(x), y) \) is also included in \( W^m(\mathcal{X}) \) for all \( y \in \{\pm 1\} \). Therefore, \( \hat{h}_W(x) := E_{Y|x}[\ell(f_W(x), Y)] \)(= \( h(f_W(x)|x) \)) is also included in \( W^m(\mathcal{X}) \). Moreover, \( \|\hat{h}_W\|_{W^m} \leq C \) uniformly over all \( W \in \mathcal{H} \).

In this setting, it is known that the following inequality holds
\[ \|\hat{h}_W - h^*\|_{\infty} \leq C \|\hat{h}_W - h^*\|_{L_2(P_X)}^{1-\frac{1}{m}}\|\hat{h}_W - h^*\|_{W^m}, \]
(see [3, 62]). Combining this with the assumption \( h^* \in W^m(\mathcal{X}) \) and the fact \( \|\hat{h}_W\|_{W^m} \leq C \), if \( \|\hat{h}_W - h^*\|_{L_2(P_X)} \leq \epsilon \) for sufficiently small \( \epsilon \), we have an \( L_\infty \)-norm bound as \( \|\hat{h}_W - h^*\|_{\infty} \leq C\epsilon^{1-\frac{1}{m}} \).

Thus, if we choose \( \epsilon^{1-\frac{1}{m}} = \Theta(\delta) \), then \( W \) satisfying \( \|\hat{h}_W - h^*\|_{L_2(P_X)} \leq \epsilon \) admits
\[ \|\hat{h}_W - h^*\|_{\infty} < \delta/2. \]

Then, by the assumption that \( h^*(x) \leq \log(2) - \delta \), it holds that
\[ \hat{h}_W(x) < \log(2) - \delta/2 \text{ (a.s.),} \]
which indicates that
\[ P_X(\text{sign}(f_W(X)) = g^*(X)) = 1. \]
Therefore, we only need to bound the quantity $\|h_{W_k} - h^*\|_{L_2(P_X)}^2$ for $W_k \sim \pi_k$.

Here, we show that the Bernstein condition (Assumption 2) is satisfied with $s = 1$ under Assumptions 3. By Assumptions 3 and $\|f_W\|_\infty \leq R$ for any $W \in \mathcal{H}$ by the definition of the clipping operator, it holds that $\|f^*\|_\infty \leq R$. Therefore, Lemma 3 yields the Bernstein condition with $s = 1$ and $C_B = 4 + 2R$. Therefore, $\|h_{W_k} - h^*\|_{L_2(P_X)}^2$ can be bounded as

$$\|h_{W_k} - h^*\|_{L_2(P_X)}^2 \leq E_Z[(\ell(f_{W_k}, Z) - \ell(f^*, Z))^2] \leq C_B(L(W) - L(f^*)) = C_B(L(W) - L(f^*)), $$

where we used Jensen’s inequality in the first inequality, and we applied $s = 1$ we have shown above to the last equality. First, we consider the stationary distribution. For any $\epsilon' > u^*$, we have already shown in the proof of Theorem 2 (See Eq. (18) ) that

$$E_{\mathcal{D}^n}[\pi_\infty(\{W \in \mathcal{H} | L(W) - L(f^*) \geq \epsilon'\})] = C \exp(-c_\beta u^* \times (\epsilon'/u^*)) = C \exp(-c_\beta \epsilon'). $$

Next, we consider the intermediate solution $W_k$. Suppose that the sample size $n$ is sufficiently large and $\lambda$ is appropriately chosen with sufficiently large $\beta$ so that $u^* \ll \delta^{2m/(2m-d)}$. The probability of misclassification is bounded by

$$E[\pi_k(\{W_k \in \mathcal{H} | P_X(\text{sign}(f_{W_k}(X)) = \text{sign}(f^*(X))) \neq 1\})] \leq E[P_{W_k \sim \pi_k}[L(W_k) - L(f^*) \geq \epsilon/C_B]]$$

$$= E[P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W) - (L(f^*) - L(W)) \geq \epsilon/C_B]]$$

$$\leq E[P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W) \geq \epsilon/(2C_B)] + E[P_{W \sim \pi_\infty}[L(f^*) - L(W) \geq \epsilon/(2C_B)]$$

$$\leq E[E_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W)]/\epsilon/(2C_B)] + E[E_{W \sim \pi_\infty}[L(f^*) - L(W) \geq \epsilon/(2C_B)]$$

$$\overset{\sim}{\leq} \frac{\Xi_k}{\delta^{2m/(2m-d)}} + \exp(-c'\beta \delta^{2m/(2m-d)}),$$

where we used $\epsilon = \Theta(\delta^{2m/(2m-d)})$ and Eq. (20) in the last inequality. Therefore, for a fixed $\delta$, we can obtain the Bayes classifier with high probability by setting $\eta$ sufficiently small and taking sufficiently large $k$.

**Making the first term as large as the second term.**

We see that the first term in the right hand side is coming from the bound of $E[P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W) \geq \epsilon/(2C_B)]].$ To bound this, we used the following bound:

$$P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W) \geq \epsilon/(2C_B)] \leq E_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W)]/\epsilon/(2C_B))$$

$$\overset{\sim}{\leq} \frac{\Xi_k}{\delta^{2m/(2m-d)}},$$

almost surely. Therefore, if $\Xi_k$ is sufficiently small such that $\frac{\Xi_k}{\delta^{2m/(2m-d)}} \ll 1$, then we have

$$P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k) - L(W) \geq \epsilon/(2C_B)] \leq 1/2.$$

Therefore, by running the algorithm $S$-times and picking up the beset $W_k$ in terms of the validation error (write it as $W_k(S)$), then we have that

$$P_{W_k \sim \pi_k, W \sim \pi_\infty}[L(W_k(S)) - L(W) \geq \epsilon/(2C_B)] \leq 1/2^S.$$
Thus, for sufficiently large $S$ such that the right hand side can be smaller than the second term $\exp(-c' \beta^2 m/(2m-d))$, then we have that

$$E \left\{ P_{W_k}^X \left[ P_X (\text{sign}(f_{W_k}(X)) = \text{sign}(f^*(X))) \neq 1 \mid D^n \right] \right\} \lesssim \exp(-c' \beta^2 m/(2m-d)).$$

$\square$

**Lemma 3.** Suppose that $\|f^*\|_\infty \leq R$ and $\sup_W \|f_W\|_\infty \leq R$. Then, the logistic loss satisfies the Bernstein condition with $s = 1$ and $C_B = 4 + 2R$.

**Proof.** Since $\|f^*\|_\infty \leq R$, it holds that $|h^*(x)| = |h(f^*(x)|x) is also bounded by $R$ (a.s.). Here, we fix $x \in X$ and write $p = P(Y = 1|X = x)$. By the optimality of $f^*(x)$, we have that $p = \frac{1}{1+\exp(-f^*(x))}$.

Accordingly, we denote $q = \frac{1}{1+\exp(-f_W(x))}$.

Then, what we need to show is that

$$p \left[ \log \left( \frac{p}{q} \right) \right]^2 + (1-p) \left[ \log \left( \frac{1-p}{1-q} \right) \right]^2 \leq C_B \left\{ p \log \left( \frac{p}{q} \right) + (1-p) \log \left( \frac{1-p}{1-q} \right) \right\}. \quad (21)$$

The right hand side can be rewritten as

$$p \left[ \log \left( \frac{p}{q} \right) \right]^2 + \frac{1}{p} (q-p) + (1-p) \left[ \log \left( \frac{1-p}{1-q} \right) - \frac{1}{1-p} (q-p) \right],$$

and by noticing the convexity of $-\log(\cdot)$, each term of the right hand side is non-negative. We show the inequality (21) by showing

$$\left[ \log \left( \frac{p}{q} \right) \right]^2 \leq C_B \left[ \log \left( \frac{p}{q} \right) + \frac{1}{p} (q-p) \right], \quad (22)$$

$$\left[ \log \left( \frac{1-p}{1-q} \right) \right]^2 \leq C_B \left[ \log \left( \frac{1-p}{1-q} \right) - \frac{1}{1-p} (q-p) \right]. \quad (23)$$

(I) Proof of Eq. (22). We show the inequality by considering the following four settings (i) $p/2 \leq q \leq p$, (ii) $q < p/2$, (iii) $p \leq q \leq 2p$, (iv) $2p < q$. Let $f_1(q) = \log(p/q) + \frac{1}{p} (q-p)$ and $f_2(q) = |\log(p/q)|^2$.

(i) $(p/2 \leq q \leq p)$ Since $f_1(q)$ is a convex function satisfying $\frac{d^2}{dq^2} f_1(q) = 1/q^2 \geq 1/p^2 > 0$, $f_1(p) = 0$ and $f_1(q) \geq 0$, it holds that $f_1(q) \geq \frac{1}{p^2} (q-p)^2$ for all $q \leq p$. On the other hand, $0 \leq \log(p/q) \leq \frac{2}{p} (q-p)$ for $p/2 \leq q \leq p$, it holds that $f_2(q) \leq \frac{2}{p^2} (q-p)^2$ $(q \leq p)$. Therefore, we have that

$$4f_1(q) \geq f_2(q) \quad (p/2 \leq \forall q \leq p).$$

(ii) $(q < p/2)$. Since $f_1(q) \geq \frac{1}{p^2} (q-p)^2$ $(q \leq p)$ and $-\frac{1}{p} (q-p) \leq \frac{2}{p^2} (q-p)^2 \leq 2f_1(q)$ $(\forall q \leq p/2)$, we have that

$$-\frac{1}{3} \log(p/q) \leq \frac{1}{p} (q-p) \leq 0 \quad (\forall q \leq p/2).$$

Therefore, we have that

$$f_1(q) \geq \frac{2}{3} \log(p/q) \geq \frac{2}{3 \log(p/q)} |\log(p/q)|^2 \geq \frac{2}{3 \log(1+\exp(R))} f_2(q),$$

where we used $p \leq 1$ and $q = \frac{1}{1+\exp(-f_W(x))} \geq \frac{1}{1+\exp(R)}$.

(iii) $(p \leq q \leq 2p)$. In this setting, the convexity of $-\log(\cdot)$ gives $0 \geq \log(p/q) = -\log(q/p) \geq \frac{1}{2} (p-q)$. Therefore, it holds that $f_2(q) \leq \frac{1}{p^2} (p-q)^2$. On the other hand, since $f_2'(q) = \frac{1}{q^2} \geq \frac{1}{4p^2}$, it holds that $f_1(x) \geq \frac{1}{4p^2} (p-q)^2$. Therefore, we have

$$4f_1(q) \geq f_2(q) \quad (p \leq \forall q \leq 2p).$$

28
(iv) \(2p < q\). By the convexity of \(- \log(q)\), we have that
\[
-\frac{1}{\log(2)} \log(q/p) \geq -\frac{1}{p \log(2)} (q - 2p) - 1 \geq -\frac{1}{p} (q - 2p) - 1 = -\frac{1}{p} (q - p) \quad (\forall q > 2p).
\]
This yields that
\[
f_1(q) \geq \left(1 - \frac{1}{\log(2)}\right) \log(p/q) = \frac{1 - \log(2)}{\log(2)} \log(q/p) \geq 0 \quad (\forall q > 2p).
\]
(Recall that \(\log(2) < 1\)). Therefore,
\[
f_1(q) \geq \frac{1 - \log(2)}{\log(2) \log(q/p)} \log(q/p) \geq \frac{1 - \log(2)}{\log(2) \log(1 + \exp(R))} \log(q/p)^2
\]
\[
= \frac{1 - \log(2)}{\log(2) \log(1 + \exp(R))} f_2(q) \quad (\forall q > 2p),
\]
where we used \(q \leq 1\) and \(p \geq \frac{1}{1 + \exp(R)}\).

(II) Proof of Eq. \(2\). This is shown completely in the same manner with the proof of Eq. \(22\) by setting \(p \leftarrow 1 - p\) and \(q \leftarrow 1 - q\).

(III) Combining (I) and (II), we have the equations \(22\) and \(23\) with
\[
C_B = \max \left\{ 4, \frac{3}{2} \log(1 + \exp(R)), \frac{\log(2)}{1 - \log(2)} \right\} \log(1 + \exp(R)) \leq 4 + 2R,
\]
where we used \(\frac{3}{2} \leq \frac{\log(2)}{1 - \log(2)} \leq 3, \frac{\log^2(2)}{1 - \log(2)} \leq 2, \text{ and } \log(1 + \exp(R)) \leq \log(2) + R\) by the Lipschitz continuity of \(x \mapsto \log(1 + \exp(x))\). Therefore, by resetting \(C_B = 4 + 2R\), we obtain the assertion. \(\square\)

D.4 Derivation of the fast rate of regression (Eq. \(10\))

Since \(f^*\) is realized by \(f_{W^*}\), \(\|f_W\|_\infty \leq R\) for any \(W \in \mathcal{H}\) and \(\epsilon_i \leq C\), we have that
\[
\ell(Y, f_W(X)) = (Y - f_W(X))^2 = (f_{W^*} + \epsilon - f_W(X))^2 \leq 2((f_{W^*}(X) - f_W(X))^2 + \epsilon^2) \leq 2(4R^2 + C^2).
\]
Therefore, the assumption \(0 \leq \ell(Y, f_W(X)) \leq \tilde{R} \) (\(\forall W \in \mathcal{H}\) (a.s.) is obtained by \(\tilde{R} = 2(4R^2 + C^2)\). Other assumptions in
Write \(\mathcal{H}_{K^\theta} : = \mathcal{H}_{K^\theta(\gamma + 1)}\). As we have stated in the main text, we can show the “bias” and “variance” terms can be bounded as
\[
\inf_{h \in \mathcal{H}_{K^\theta}} \mathcal{L}(h) - \mathcal{L}(f^*) \leq \epsilon \Rightarrow \lambda_{\beta} \|h\|_{\mathcal{K}}^2 \lesssim \lambda_{\beta} \epsilon^{\frac{2(1 - \theta)}{\theta - \gamma}},
\]
\[
- \log \bar{\nu}_\beta(\{h \in \mathcal{H} : \|h\|_H \leq \epsilon\}) \lesssim (\epsilon/\lambda_{\beta}^{1/2}) - \frac{\bar{w}}{\lambda_{\beta}^{1/2}}.
\]
The variance term has been already evaluated in Eq. \(10\). Now, we evaluate the bias term. By the definitions of \(\mathcal{H}_{K^\theta}\), \(W^* \in \mathcal{H}_{K^\theta}\) means there exists \((a_k)_{k=0}^\infty\) such that
\[
W^* = \sum_{k=0}^{\infty} \sqrt{\mu_k} \theta(\gamma + 1) a_k e_k, \quad \text{and} \quad \sum_{k=0}^{\infty} a_k^2 < \infty.
\]
Here, we denote \(Q := \sum_{k=0}^{\infty} a_k^2\). Now, let \(\tilde{W} = \sum_{k=0}^{N} \sqrt{\mu_k} \theta(\gamma + 1) a_k e_k\) for some \(N \in \mathbb{N}\) as an approximator of \(W^*\). Then, its norm in \(\mathcal{H}_{K^\theta}\) can be evaluated as
\[
\|\tilde{W}\|_{K^\theta}^2 = \sum_{k=0}^{N} \mu_k \theta(\gamma + 1) a_k^2 = \sum_{k=0}^{N} \mu_k^{(\theta - 1)(\gamma + 1)} a_k^2.
\]
}\]
We evaluate the discrepancy between $W^*$ and $\tilde{W}$ and evaluate its norm in $\mathcal{H}$. Since $W^* - \tilde{W} = \sum_{k=N+1}^{\infty} \sqrt{\mu_k} \gamma_{k+1} a_k e_k$, its $\mathcal{H}$-norm is given by

$$\|W^* - \tilde{W}\|_H^2 = \sum_{k=N+1}^{\infty} \mu_k^{\theta(\gamma + 1)} a_k^2.$$  \hspace{1cm} (25)

Note that $\mathcal{L}(f_{\tilde{W}}) - \mathcal{L}(f^*) = \|f_{\tilde{W}} - f^*\|_{\mathcal{L}_2(P_X)}^2 \leq (1 + RD)\|W - W^*\|_H^2$ by Lemma 11. Therefore, to ensure $\mathcal{L}(f_{\tilde{W}}) - \mathcal{L}(f^*) \leq \epsilon^2$, it suffices to let $(1 + RD)\|W - W^*\|_H^2 \leq \epsilon^2$. By Eq. (25), this means that

$$\sum_{k=N+1}^{\infty} \mu_k^{\theta(\gamma + 1)} a_k^2 \leq \frac{\epsilon^2}{(1 + RD)}.$$  

Hence, by setting $N \propto \frac{\epsilon^{-1/\theta(\gamma + 1)}}{\theta(\gamma + 1)}$, we can let $\mathcal{L}(f_{\tilde{W}}) - \mathcal{L}(f^*) \leq \epsilon^2$. In this setting of $N$, Eq. (24) gives that

$$\|\tilde{W}\|_H^2 \leq \sum_{k=0}^{N} c_{\mu}^{(\theta - 1)(\gamma + 1)} (k + 1)^{-(\theta - 1)(\gamma + 1)} a_k^2$$

$$\leq c_{\mu}^{(\theta - 1)(\gamma + 1)} (N + 1)^{-(\theta - 1)(\gamma + 1)} Q \leq \epsilon^2(\theta - 1)/\theta,$$

which gives the bias term bound.

Combining the bias and variance terms, we may choose $\epsilon^*$ as the infimum of $\epsilon$ such that $\lambda_\beta \epsilon^{2(1-\theta)/\theta} + (\epsilon/\lambda_\beta^{1/2}) \frac{1}{4\pi \lambda_\beta} \leq \beta \epsilon^2$. That is, we have that

$$\epsilon^* = \max \left\{ \lambda_\beta^{-\tilde{a}} \beta^{-(1-\tilde{a})}, \left( \frac{\lambda_\beta}{\beta} \right)^\theta, n^{-\frac{1}{\theta - 2}} \right\} = \max \left\{ \lambda^{-\tilde{a}} \beta^{-1}, \lambda^\theta, n^{-\frac{1}{\theta - 2}} \right\}.$$
