CHOP mediates ASPP2-induced autophagic apoptosis in hepatoma cells by releasing Beclin-1 from Bcl-2 and inducing nuclear translocation of Bcl-2

Apoptosis-stimulating protein of p53-2 (ASPP2) induces apoptosis by promoting the expression of pro-apoptotic genes via binding to p53 or p73; however, the exact mechanisms by which ASPP2 induces apoptotic death in hepatoma cells are still unclear. Here, we show that the transient overexpression of ASPP2 induces autophagic apoptosis in hepatoma cells by promoting p53- or p73-independent C/EBP homologous protein (CHOP) expression. CHOP expression decreases the expression of Bcl-2; this change releases Beclin-1 from cytoplasmic Bcl-2-Beclin-1 complexes and allows it to initiate autophagy. However, transient overexpression of Beclin-1 can induce autophagy but not apoptosis. Our results show that ASPP2 induces the expression of damage-regulated autophagy modulator (DRAM), another critical factor that cooperates with free Beclin-1 to induce autophagic apoptosis. The effect of CHOP on the translocation and sequestration of Bcl-2 in the nucleus, which requires the binding of Bcl-2 to ASPP2, is also critical for ASPP2-induced autophagic apoptosis. Although the role of nuclear ASPP2–Bcl-2 complexes is still unclear, our results suggest that nuclear ASPP2 can prevent the translocation of the remaining Bcl-2 to the cytoplasm by binding to Bcl-2 in a CHOP-dependent manner, and this effect also contributes to Beclin-1-initiated autophagy. Thus, CHOP is critical for mediating ASPP2-induced autophagic apoptosis by decreasing Bcl-2 expression and maintaining nuclear ASPP2–Bcl-2 complexes. Our results, which define a mechanism whereby ASPP2 overexpression induces autophagic apoptosis, open a new avenue for promoting autophagy in treatments to cure hepatocellular carcinoma.

Cell Death and Disease (2014) 5, e1323; doi:10.1038/cddis.2014.276; published online 17 July 2014

Apoptosis-stimulating protein of p53-2 (ASPP2) belongs to the evolutionarily conserved ASPP family. Members of this family are characterized by the presence of ankyrin repeats, an SH3 domain, and a protein-rich region.1,2 ASPP2 was previously identified as an interacting partner for several proteins, for example, Bcl-2 and p53.3 ASPP2 binds to p53 through its C terminus to stimulate the transactivation function of p53 on the promoters of pro-apoptotic genes, such as the genes encoding Bax, PIG3 and PUMA. ASPP2 is a haploinsufficient tumor suppressor; ASPP2−/− mice are prone to developing cancer.5 Recently, ASPP2 has been reported to bind RAS and to regulate autophagy by binding Atg5 via its N terminus.5,6

Autophagy is an evolutionarily conserved pathway for maintaining cellular homeostasis through the targeting of proteins and organelles to lysosomes for degradation.7 Upon induction, a small vesicular sac elongates and subsequently encloses a portion of the cytoplasm, forming a double-membrane structure known as an autophagosome. The autophagosome then fuses with a lysosome to form an autophagosome in which the enclosed materials are degraded.8 The release of Beclin-1 from Bcl-2–Beclin-1 complexes is critical for inducing autophagy as free Beclin-1 is needed to interact with VPS34 and initiate autophagosome formation.9

Therapeutic approaches for hepatocellular carcinoma (HCC) that aim to increase the amount of autophagy have been successfully tested in vitro and in vivo.10 Furthermore, mice with heterozygous disruption of Beclin-1 have a high frequency of spontaneous HCC.11 These data suggest that maintaining and increasing autophagy is beneficial for preventing and curing HCC.

The transcription factor C/EBP homologous protein (CHOP) regulates certain aspects of the cellular response to stress.12,13 CHOP has been implicated in the regulation of energy metabolism, cellular proliferation and differentiation and the expression of cell type-specific genes.14 CHOP expression is low in non-stressed conditions but is markedly increased in response to ER stress, amino-acid starvation and adipocytic differentiation.15–17 The overexpression of CHOP promotes apoptosis in several cell lines.18 CHOP reduces the expression of Bcl-2, an antiapoptotic factor that prevents the translocation of Bax to the mitochondria, which results in the induction of apoptosis.19 Bcl-2 is known to interact with Beclin-1, an initiator of autophagy.19 Autophagy is also regarded as an inducer of apoptosis, and a previous study reported that damage-regulated autophagy modulator (DRAM) expression is critical for inducing autophagic apoptosis.8
The relationship between autophagy and apoptosis is still unclear, and the detailed mechanisms of ASPP2 function in autophagy and apoptosis have not been fully elucidated. In this study, we observed that transient overexpression of ASPP2 induces CHOP-mediated autophagic apoptosis in hepatoma cells.

Results

ASPP2 overexpression induces CHOP in a p53- or p73-independent manner; however, CHOP is still involved in ASPP2 overexpression-induced apoptosis in hepatoma cells. HCC cell lines (Hep1-6, HepG2, Hep3B and Huh7) were transfected with a plasmid expressing ASPP2 for 24 h. We used immunofluorescence to observe that ASPP2 overexpression induced the expression of CHOP (Figures 1a and b, Supplementary Figure 1a). ASPP2 overexpression-induced CHOP was located mostly in the nucleus (Figure 1a). The vector did not induce CHOP expression in every hepatoma cell line (data not shown). The results of immunoblotting, M30 immunofluorescence and flow cytometry showed that ASPP2 overexpression promoted apoptosis in all cell lines (Figures 1c–e and Supplementary Figures 1b and f). An MTT assay further showed that ASPP2 overexpression promoted cell death in all cell lines (Supplementary Figure 1c). Thus, ASPP2 overexpression induces apoptotic cell death in hepatoma cells.

Figure 1  ASPP2 overexpression induces p53-independent CHOP-mediated apoptosis in Hep1-6 cells. Hep1-6 cells were transfected with a plasmid encoding ASPP2 (ASPP2 Pl) for 24 h. (a) Immunofluorescence detection of the expression of ASPP2 and CHOP. Nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI). Magnification, × 400. (b) Quantification of cells positive for CHOP expression as seen in a. Data are shown as the mean ± S.E.M. of three independent experiments. (c) Immunoblot assay was used to evaluate the level of CHOP and cleaved PARP fragment (p85) in Hep1-6 cells using the indicated antibodies. (d) Immunofluorescence detection of M30-positive Hep1-6 cells. Nuclei were stained with DAPI. (e) Quantification of M30-positive cells as seen in d. Data are shown as the mean ± S.E.M. of three independent experiments. (f) Immunoblot assay was used to detect the effect of CHOP knockdown via siRNA (CHOP si) on apoptosis in Hep1-6 cells using the indicated antibodies (top panel). The ratio of p85 to β-actin was calculated from densitometry scanning data. Data are shown as the mean ± S.E.M. of three independent experiments (bottom panel). (g) Immunoblot assay was used to detect the effect of p53 knockdown via siRNA (p53 si) on CHOP expression and apoptosis in Hep1-6 cells using the indicated antibodies.
The inhibition of CHOP expression via siRNA decreased the level of cleaved PARP fragment (p85) in Hep1-6, HepG2 and Hep3B cells, suggesting that ASPP2 overexpression can induce apoptosis in HCC by promoting CHOP expression (Figure 1f, Supplementary Figures 1d and f). We used p53 siRNA to inhibit p53 expression and observed that p53 knockdown failed to downregulate CHOP expression in Hep1-6 (Figure 1g) and HepG2 cells (Supplementary Figure 1e). We also failed to detect that p73 could mediate CHOP expression in Hep3B and Huh7 cells transfected with the ASPP2 plasmid (Figure 6b and Supplementary Figure 1f). However, knockdown of p53 in Hep1-6 and HepG2 cells or knockdown of p73 in Hep3B and Huh7 cells decreased ASPP2 overexpression-induced apoptosis (Figures 1g and 6b, Supplementary Figures 1e and f). Thus, although ASPP2 overexpression induces CHOP expression in a p53- or p73-independent manner, CHOP is still involved in ASPP2-induced p53- or p73-mediated apoptosis.

ASPP2-induced CHOP mediates autophagic apoptosis in hepatoma cells. Bcl-2 is a classic antiapoptotic factor in cells. Previous studies have shown that CHOP can downregulate the level of Bcl-2 expression. In this study, ASPP2 overexpression decreased the levels of Bcl-2 mRNA and protein in Hep1-6 cells (Figures 2a and b). Bcl-2 is also reported to inhibit autophagy via binding to Beclin-1. Here, we failed to detect that ASPP2 overexpression significantly affected the levels of Beclin-1 mRNA and protein in Hep1-6 cells (Figures 2a and b). However, ASPP2 overexpression increased LC3 II expression, upregulated the ratio of LC3 II/I and decreased p62 level in Hep1-6 cells (Figures 2b and e and Supplementary Figure 2a). Exposure to BafA 1, an inhibitor of autophagic flux, increased the accumulation of LC3 II and p62 and upregulated the ratio of LC3 II/I in Hep1-6 cells with ASPP2 overexpression compared with cells that did not receive treatment with BafA 1 (Figure 2c and Supplementary Figure 2a). BafA 1 treatment had no effect on the expression of ASPP2 and CHOP (Figure 2c and Supplementary Figure 2c). We also detected that Atg5 knockdown via siRNA inhibited ASPP2-induced autophagy as shown by decrease of LC3 II and increase of p62 (Figure 2f). These data suggest that ASPP2 overexpression can induce autophagy in hepatoma cells.

Interestingly, using immunofluorescence, we observed that ASPP2 overexpression-induced GFP-LC3 II puncta were present in HCC cells positive for CHOP expression (Figure 3b and Supplementary Figure 2e). Knockdown of CHOP via siRNA significantly decreased the number of cells with GFP-LC3 II puncta (Supplementary Figure 2e and f). Immunoblot assay also indicated that knockdown of CHOP via siRNA inhibited ASPP2 overexpression-induced autophagy in Hep1-6 cells (Figure 2d and Supplementary Figure 2b). Knockdown of CHOP via siRNA had no effect on the expression of ASPP2 and Beclin-1 in Hep1-6 cells with or without ASPP2 overexpression (Figure 2d and Supplementary Figure 2d). Thus, CHOP is an ASPP2 overexpression-induced modulator of autophagy. As inhibition of autophagy via BafA 1 or Atg5 siRNA decreases ASPP2-induced apoptosis and cell death (Figures 2f and g and Supplementary Figure 2g), and CHOP knockdown via siRNA decreases ASPP2-induced autophagy and apoptosis, our data suggest that CHOP expression-induced autophagy is involved in ASPP2 overexpression-induced apoptosis. Furthermore, transfection with a plasmid encoding Bcl-2 inhibited ASPP2 overexpression-induced autophagy and apoptosis but had no effect on CHOP, Beclin-1 and ASPP2 levels (Figure 2e). We failed to detect that ASPP2 overexpression suppressed the AKT/mTOR axis (Supplementary Figure 4a). In addition, we also failed to detect that ASPP2 overexpression induced Tribbles homologue 3 (TRIB3) expression and that TRIB3 bound to AKT directly (Supplementary Figure 4b).

Taken together, our data suggest that ASPP2 overexpression induces CHOP expression, which mediates autophagic apoptosis in hepatoma cells. The mechanism by which CHOP induces autophagic apoptosis is associated with downregulation of Bcl-2 expression.

ASPP2 overexpression releases Beclin-1 from Bcl-2–Beclin-1 complexes and the released Beclin-1 initiates ASPP2-induced autophagy. Using immunofluorescence, we determined that ASPP2 overexpression reduced Bcl-2 expression and that, in the cytoplasm of Hep1-6 cells, localization of Bcl-2 and Beclin-1 did not overlap (Figure 3a) as remaining Bcl-2 translocated to the nucleus (Supplementary Figure 3a). Autophagy was induced in ASPP2- and CHOP-positive cells (Figure 3b). In Supplementary Figure 3b, we further identified that Beclin-1 colocalized with GFP-LC3 puncta in ASPP2-overexpressed cells, and Beclin-1 knockdown via siRNA reduced ASPP2-induced GFP-LC3 puncta and GFP-LC3 puncta-positive cells (data not shown). Moreover, after transfection of Hep1-6 cells with a plasmid encoding Bcl-2, we observed that Bcl-2 overexpression rescued the colocalization of Bcl-2 and Beclin-1 in the cytoplasm and inhibited autophagy (Supplementary Figures 3b and c). Immunoblot assays showed that Beclin-1 knockdown via siRNA reduced the levels of LC3 II and the ratio of LC3 II/I and increased the accumulation of p62 (Figures 3c and d). These data suggest that the released Beclin-1 is involved in ASPP2 overexpression-induced autophagy. We also identified that knockdown of Beclin-1 via siRNA reduced ASPP2 overexpression-induced cleavage of PARP (p85; Figures 3c and e); however, Beclin-1 siRNA treatment itself had no effect on apoptosis (Figure 3f). Control siRNA treatment also had no effect on autophagy and apoptosis (Figure 3f). These data suggest that the downregulation of Bcl-2 expression promotes the release of Beclin-1 from Bcl-2–Beclin-1 complexes; the released Beclin-1 then initiates ASPP2-induced autophagy, which induces apoptosis in hepatoma cells with ASPP2 overexpression.

CHOP is important for maintaining nuclear ASPP2–Bcl-2 complexes and for releasing Beclin-1 from Bcl-2–Beclin-1 complexes by downregulating Bcl-2 expression. Previous results indicate that the remaining Bcl-2 translocates to the nucleus in Hep1-6 cells after the overexpression of ASPP2. As the majority of ASPP2 also translocated to the nucleus when overexpressed, we investigated whether ASPP2 could bind Bcl-2 in the extracted nuclei. Using an immunoprecipitation assay, we determined that ASPP2 overexpression...
increased the level of ASPP2–Bcl-2 complexes in the extracted nucleus of Hep1-6 cells, although CHOP expression dramatically decreased the overall level of Bcl-2 (Figure 4a). Using an immunoblot assay to detect Bcl-2 levels in the extracted nucleus and cytoplasm, we further identified that ASPP2 overexpression promoted the translocation of the remaining Bcl-2 to the nucleus (Figure 4b). These data suggest that the majority of the transiently overexpressed ASPP2 binds Bcl-2 in the nucleus. A targeted siRNA knockdown of CHOP increased the total level of Bcl-2 (Figure 2d); however, CHOP inhibition decreased the level of nuclear Bcl-2 and increased the level of cytoplasmic Bcl-2 (Figure 4c). Moreover, immunoprecipitation results showed that the inhibition of CHOP expression decreased the level of nuclear ASPP2–Bcl-2 complexes and restored the level of cytoplasmic Bcl-2–Beclin-1 complexes (Figures 4d and e). Knockdown of CHOP did not affect the expression (Figure 2d and Supplementary Figure 2d) and distribution of ASPP2 (data not shown). Thus, CHOP is important for maintaining the interaction of ASPP2 and Bcl-2 in the nucleus and for preventing the formation of Bcl-2–Beclin-1 complexes in the cytoplasm. Cytoplasmic Bcl-2 is an antiapoptotic factor, whereas nuclear Bcl-2 can promote apoptosis. This suggests that the distinct distributions of Bcl-2 have differing functions.20 Moreover, we did not detect that CHOP could directly bind to ASPP2, Bcl-2 or Beclin-1 (Supplementary Figure 5).
Thus, our results suggest that the transient overexpression of ASPP2 can suppress cytoplasmic Bcl-2 by binding to it in the nucleus in a CHOP-dependent manner.

**Beclin-1-initiated autophagy is involved in ASPP2-induced apoptosis but is not sufficient for its induction.** We have shown that Beclin-1 is released from cytoplasmic Bcl-2–Beclin-1 complexes and can then initiate ASPP2 overexpression-induced autophagy in HCC cells. Accordingly, the transient overexpression of Beclin-1 enhanced ASPP2 overexpression-induced apoptosis by promoting increased autophagy development in Huh7 and Hep1-6 cells in a CHOP-independent manner (Figures 5a, b, d and e). These results suggest that Beclin-1-initiated autophagy is necessary for ASPP2-induced apoptosis. However, when Huh7 and Hep1-6 cells were transfected with the Beclin-1 plasmid solely, Beclin-1 overexpression induced autophagy but not apoptosis, suggesting that promoting Beclin-1-initiated autophagy is not sufficient for the induction of apoptosis (Figures 5c and f). Moreover, as knockdown of p53 in Hep1-6 cells and knockdown of p73 in Hep3B cells decrease ASPP2 overexpression-induced autophagic apoptosis (Figure 1g, Supplementary Figures 1f and g), we believe that other factors might be involved in ASPP2-induced autophagic apoptosis and these factors might be regulated by p53 or p73.

**ASPP2 induces CHOP-independent expression of DRAM, and the ASPP2-induced DRAM promotes autophagic apoptosis.** Previous studies have shown that DRAM expression induces autophagy and that DRAM-induced autophagy is an inducer of apoptosis. In this study, we observed that ASPP2 overexpression increased DRAM mRNA and protein in Hep1-6, Huh7 and Hep3B cells (Figures 6a and b and Supplementary Figure 1f). By using siRNA to knockdown DRAM expression, we detected decreased levels of ASPP2-induced apoptosis and autophagy, suggesting that DRAM is involved in ASPP2-induced autophagic apoptosis (Figures 6c and d and Supplementary Figure 1f). Moreover, we detected that ASPP2-induced DRAM expression was p53-dependent in Hep1-6 and HepG2 cells and was p73-dependent in Huh7 and Hep3B cells (Figure 6b, Supplementary Figures 1e–g). Immunoblot assay showed that DRAM knockdown via siRNA did not affect...
CHOP expression in Hep1-6, Huh7 and Hep3B cells with or without ASPP2 overexpression, suggesting that CHOP expression is independent of DRAM (Figure 6c and Supplementary Figure 1f). The results of immunoblotting and immunofluorescence assays also showed that CHOP did not affect DRAM expression in Hep1-6 and Huh7 cells.

Figure 3  ASPP2 overexpression releases Beclin-1 from cytoplasmic Bcl-2–Beclin-1 complexes and then the released Beclin-1 induces autophagy. Hep1-6 cells were transfected with a plasmid encoding ASPP2 for 24 h. (a and b) Fluorescence microscopy was used to detect the colocalization of ASPP2 (blue), Bcl-2 (green) and Beclin-1 (red) (a) or the colocalization of ASPP2 (blue), GFP-LC3 puncta (green) and CHOP (red) (b). Magnification, ×1000. (c) Hep1-6 cells were transfected with a plasmid encoding ASPP2 (ASPP2 Pl) or co-transfected with the ASPP2 Pl and Beclin-1 siRNA (Beclin-1 si) for 24 h. Immunoblot assay was used to detect levels of LC3 I/II, p62, PARP and ASPP2. (d and e) The ratio of LC3 II/I (d) and p85/β-actin (e) was calculated from densitometry scanning data in c. Data of the ratio of LC3 II/I and p85/β-actin are shown as the mean ± S.E.M. of three independent experiments. (f) Immunoblot assay was used to detect the effects of Beclin-1 si (left panel) or control siRNA (control si, right panel) treatment on autophagy, apoptosis and ASPP2 expression in Hep1-6 cells.
with or without transfection with the ASPP2 plasmid, implying that DRAM expression is independent of CHOP (Figures 7a–e). We also did not detect that DRAM could affect the interaction of Bcl-2 with Beclin-1 or the interaction of ASPP2 with Bcl-2 (Supplementary Figures 6a and b). Moreover, simultaneous knockdown of p53 and CHOP in Hep1-6 cells or simultaneous knockdown of p73 and CHOP in Hep3B cells could produce a stronger inhibition of autophagy and apoptosis than knockdown of p53/p73 or CHOP alone, suggesting that both CHOP and p53/p73 have a major role in inducing autophagic apoptosis in response to ASPP2 overexpression (Supplementary Figure 7). Taken together, we suggest that p53- or p73-mediated DRAM expression and CHOP-released Beclin-1 act in concert to induce autophagic apoptosis in hepatoma cells when ASPP2 is transiently overexpressed. In addition, CHOP promotes the interaction between ASPP2 and Bcl-2 in the nucleus, which also contributes to ASPP2-induced autophagic apoptosis (Figure 7f).

Discussion

ASPP2, an important inducer of apoptosis, has been reported to inhibit the growth of hepatoma cells in vitro and in vivo.22 Here, we show that ASPP2 can induce apoptosis via the induction of autophagy. Conversely, a recent study on the relationship between ASPP2 and autophagy concluded that ASPP2 inhibits autophagy by binding Atg5 via its N terminus.6 This discrepancy may be explained by a difference in the genetic backgrounds of the cell lines studied. The contradictory results highlight the complex relationship between ASPP2 expression and autophagy.

Our results show that ASPP2-mediated autophagy is dependent on CHOP expression. To our knowledge, few studies have focused on the relationship between ASPP2 and CHOP. We show that transfecting hepatoma cell lines with an ASPP2 plasmid induces CHOP expression and nuclear localization regardless of the cellular p53 status, suggesting that CHOP expression occurs in a p53-independent manner. As a multifunctional transcription factor, CHOP mediates gene expression by complex mechanisms. As a member of the C/EBP family, CHOP binds to other members of the C/EBP family to form heterodimers that promote or inhibit gene expression.16,17,23 CHOP can also modulate the activity of other bZIP transcription factors that do not belong to the C/EBP family.24 Many studies have demonstrated that CHOP promotes apoptosis by decreasing Bcl-2 expression,16 and our data also support this hypothesis.

As a classic antiapoptotic factor, Bcl-2 prevents Bax oligomerization in the mitochondrial outer membrane.25 However, the translocation of Bcl-2 to the nucleus is reported to induce apoptosis.20 Correspondingly, our results show that, although the level of Bcl-2 significantly decreases following the expression of CHOP, the remaining Bcl-2 does translocate to the nucleus, where it binds to ASPP2. Moreover, the persistence of

Cell Death and Disease
CHOP is critical for maintaining nuclear-localized Bcl-2. Although we do not know the role of nuclear ASPP2–Bcl-2 complexes, retaining Bcl-2 in the nucleus by binding to ASPP2 prevents the cytoplasmic translocation of Bcl-2, where it functions as a well-known antiapoptotic factor.20 The translocation of Bcl-2 to the nucleus also down-regulates the level of cytoplasmic Bcl-2–Beclin-1 complexes. Beclin-1 is an initiator of autophagy and an inhibitor of tumorigenesis; it is thought to be a haploinsufficient tumor suppressor.26 Our results show that ASPP2 overexpression does not affect Beclin-1 expression levels but does result in the release of Beclin-1 from cytoplasmic Bcl-2–Beclin-1 complexes and allows released Beclin-1 to initiate ASPP2-induced autophagy. Previous studies of Beclin-1+/−/− mutant mice have demonstrated that Beclin-1 is a tumor-suppressor gene.11,27 Further studies of mice with depletion of Atg5 or Atg7 also found that autophagy deficiency induces liver tumors.28 In our study, we determined that transient overexpression of Beclin-1 initiates autophagy but that this autophagy does not promote apoptotic cell death. We also demonstrated that Beclin-1-initiated autophagy participates in ASPP2-induced apoptosis regardless of CHOP status. These data show that the relationship between Beclin-1-induced autophagy and apoptosis is complicated and suggest that the induction of apoptosis involves additional factors.

The exact mechanisms by which autophagy induces apoptosis or protects cells from stress are still unclear. To our knowledge, DRAM is one of the first genes reported to be associated with autophagic apoptosis. Inducing DRAM expression promotes autophagic apoptosis in a p53-dependent manner.8 In a previous study, we demonstrated that DRAM-mediated autophagy is involved in fatty acid-induced apoptosis in hepatoma cells.21 However, the exact mechanisms of apoptosis induction by DRAM-mediated autophagy are still unclear. In this study, we showed that the transfection of hepatoma cells with an ASPP2 plasmid promotes DRAM expression and that the resulting DRAM-mediated autophagy promotes apoptosis. Another study demonstrated that DRAM expression can be induced by p73 when p53 is deficient but that p73-dependent DRAM expression does not induce autophagic apoptosis.29 Our results show that ASPP2 overexpression induces DRAM expression by activating p53 in HepG2 and Hep1-6 cells or by activating p73 in Hep3B and Huh7 cells, which is then able to induce autophagic apoptosis. Although the exact mechanisms of autophagy-induced apoptosis in hepatoma cells require further study, our results uncover a new relationship between ASPP2 and autophagic apoptosis. ASPP2-induced autophagic apoptosis via the promotion of CHOP expression should be investigated further as it is a novel, targetable, signaling pathway.

Figure 5 Beclin-1-initiated autophagy is involved in ASPP2-induced apoptosis but is not sufficient for its induction. (a, b and e) Huh7 (a and b) and Hep1-6 cells (d and e) were transfected with a plasmid encoding GFP-LC3 or co-transfected with one or more of the indicated plasmids or siRNA (including the ASPP2 plasmid (ASPP2 Pl), the Beclin-1 plasmid (Beclin-1 Pl) and CHOPl siRNA (CHOPl si)). Immunofluorescence assay was used to evaluate the rate of GFP-LC3 puncta-positive Huh7 (a) and Hep1-6 cells (d). Quantification of Huh7 (a) and Hep1-6 cells (d) with more than 10 GFP-LC3 puncta. Data are shown as the mean ± S.E.M. of three independent experiments. (b and e) Immunoblot assay was used to detect autophagy and apoptosis using the indicated antibodies in Huh7 (b) and Hep1-6 cells (e). (c and f) Immunoblot detection of Beclin-1 overexpression on autophagy and apoptosis in Huh7 (c) and Hep1-6 cells (f) using the indicated antibodies.

Cell Death and Disease
Figure 6  ASPP2 overexpression induces DRAM-mediated autophagic apoptosis. (a and b) Hep1-6 and Huh7 cells were transfected with the ASPP2 plasmid (ASPP2 Pl) for 24 h with or without co-transfection with p73 siRNA (p73 si). Real-time PCR and immunoblot assays were used to detect the mRNA (a) and protein (b, left panel) level of DRAM in Huh7 and Hep1-6 cells. Immunoblot assay was used to detect the effect of p73 si on DRAM, LC3 I/II, CHOP and PARP levels in Huh7 and Hep1-6 cells (b, right panel). (c) Immunoblot assay was used to detect the effects of DRAM knockdown via siRNA (DRAM si) on CHOP expression and the levels of autophagy and apoptosis in Hep1-6 and Hep7 cells with (left panel) or without (right panel) transfection with ASPP2 Pl. (d) M30 assay was used to detect the effects of DRAM knockdown on autophagy and apoptosis. (a and d) Data are shown as the mean ± S.E.M. of three independent experiments.

Materials and Methods
Cell culture and treatment. Hep1-6, HepG2 and Huh7 cells were grown in Dulbecco’s modified Eagle’s medium (DMEM), and Hep3B cells were grown in modified Eagle’s medium (MEM). DMEM and MEM were supplemented with 10% fetal bovine serum. All cells were seeded in 6- or 24-well plates, transfected for 24 h with plasmids expressing ASPP2, Beclin-1, Bcl-2 and GFP-LC3 with Fugene HD (Promega, Madison, WI, USA) or with p53, CHOP, Beclin-1, Atg5 and DRAM siRNAs using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA). The sequences of DRAM siRNA were derived from Crighton et al.

Immunoblot assay. Cell lysates, extracted nuclei and cytoplasm were subjected to western blot analysis, as described previously. Briefly, proteins was separated on 10–15% SDS-PAGE gels, and the separated proteins were then transferred to PVDF membranes. The protein blots were blocked with 5% milk and probed sequentially with specific primary antibodies and horseradish peroxidase-conjugated secondary antibodies. The detection of specific proteins on the blots was achieved with enhanced chemiluminescence (Pierce SuperSignal, Thermo Scientific, Rockford, IL, USA), and the results were captured on X-ray films. Densitometric analysis was performed using the Image-Pro Plus analysis software (Media Cybernetics, Inc., Rockville, MD, USA).

Real-time PCR. The RNeasy Mini Kit (Qiagen, Hilden, Germany) was used to isolate total RNA from cultured cells. Reverse transcription to synthesize first-strand cDNA was conducted using the SuperScript II First-stand Synthesis System for RT-PCR (Invitrogen). SYBR Green was used to detect the dsDNA products during the real-time PCR reaction. The mRNA content was normalized to the housekeeping gene β-actin. The specific primer sequences used for real-time PCR were as follows: for Bcl-2, 5′-GAGTACTGTACCGCCACCT-3′ (forward) and 5′-TCCCAGGCTTCCCTATCT-3′ (reverse); for Beclin-1, 5′-CTGGGACAACAGTTGACCAT-3′ (forward) and 5′-GGCTCTCAGATTTAACTGGTTG-3′ (reverse); for DRAM, 5′-TGATATATATGGTTTATCTG-3′ (forward) and 5′-GCCCATACGGGAGGTCTC-3′ (reverse) (the sequences of the DRAM primers are per Crighton et al.); and for β-actin, 5′-GCCCTGAGGCCGAGCTGAC-3′ (forward) and 5′-CGGATGTCCAGTACACACTT-3′ (reverse).

Fluorescence microscopy. Frozen cells were fixed with 10% paraformaldehyde/PBS, incubated in 1% Triton X-100/PBS, blocked with 3% BSA/PBS and probed with antibodies against ASPP2, CHOP, Beclin-1, Bcl-2 and GFP-LC3. Dylight 405-conjugated secondary antibodies were used to amplify the signal. Nuclei were counterstained with 4',6-diamidino-2-phenylindole. The M30 mouse antibody was produced by our laboratory and was used to detect cleaved keratin 18 in early apoptotic cells. Fluorescence microscopy was used to colocalization of Bcl-2 and Beclin-1 or the colocation of GFP-LC3 puncta and Beclin-1 or the colocation of ASPP2 and Bcl-2. For quantitative apoptosis analysis, at least 500 cells per sample were counted.

Subcellular fractionation. The cytoplasm and nuclei were extracted using a Percoll gradient centrifugation adapted from previous methods. Briefly, cells were Dounce homogenized on ice in M-SHE buffer (0.21 mol/l mannitol, 0.07 mol/l sucrose, 10 mmol/l HEPES-KOH (pH 7.4), 1 mmol/l EDTA, 1 mmol/l EGTA, 0.15 mmol/l spermine, 0.75 mmol/l spermidine and 1 mmol/l DTT) with freshly added protease inhibitors (1 μg/ml of leupeptin, aprotinin, pepstatin A, 1 mmol/l phenylmethylsulfonyl fluoride). Nuclei were pelletted at 1200 × g, and the supernatant was taken as the cytoplasmic fraction.
**Immunoprecipitation assay.** Cell lysates, extracted nuclei and cytoplasm (500 μg of protein in 500 μl of RIPA lysis buffer) were pre-cleared using protein A/G PLUS-agarose beads (Santa Cruz Biotechnology Inc.) and were incubated at 4 °C overnight with anti-ASPP2 or anti-Bcl-2 antibodies. Immunocomplexes were separated by incubation with protein A/G agarose beads and were resolved using SDS-PAGE. Immunoblot assay was performed using the anti-Bcl-2 antibody.

**Cell viability and apoptosis analysis.** Cell viability was quantified with the MTT colorimetric assay kit (Promega), and cell apoptosis was detected by flow cytometric analysis following staining with Annexin V/PI (BD PharMingen, San Diego, CA, USA), according to the instructions of the manufacturer.

**Statistical analysis.** All data shown are the results of at least three independent experiments and are expressed as the mean ± S.E.M. The differences between groups were compared using Student's t-test. Differences were considered significant at confidence levels of P<0.05, P<0.01 and P<0.001, as indicated.
