PSEUDO-EFFECTIVITY OF THE RELATIVE CANONICAL DIVISOR AND UNIRULEDNESS IN POSITIVE CHARACTERISTIC

ZSOLT PATAKFALVI

ABSTRACT. We show that if \( f: X \to T \) is a surjective morphism between smooth projective varieties over an algebraically closed field \( k \) of characteristic \( p > 0 \) with geometrically integral and non-uniruled generic fiber, then \( K_{X/T} \) is pseudo-effective.

The hardest part of the proof is to show that there is a finite smooth non-uniruled cover of the base, for which we show the following: if \( T \) is a smooth projective variety over \( k \), and \( \mathcal{A} \) is an ample enough line bundle, then a cyclic cover of degree \( p \nmid d \) given by a general element of \( |\mathcal{A}| \) is not uniruled. For this we show the following cohomological uniruledness condition, which might be of independent interest: a smooth projective variety \( T \) of dimension \( n \) is not uniruled whenever the dimension of the semi-stable part of \( H^n(T, \mathcal{O}_T) \) is greater than that of \( H^{n-1}(T, \mathcal{O}_T) \).

Additionally we also show singular versions of all the above statements.

1. INTRODUCTION

The base field \( k \) is algebraically closed and of characteristic \( p > 0 \), unless otherwise stated.

Consider a fibration \( f: X \to T \) between smooth projective varieties. Over characteristic zero ground-fields the following statement has been known for a while:

\[
(1.0.a) \quad K_{X/T} \text{ is pseudo effective whenever one of the following two equivalent conditions have been met for the geometric generic fiber } X_{\eta}:
\]

- (Psef) \( K_X \) is pseudo-effective,
- (N-ur) \( X_{\eta} \) is not uniruled.

For a precise reference we refer to [Nak04, Thm 4.1], but the statement has been implicit already in the works of Viehweg, e.g., [Vie83]. Statements of the above type, that is, statements stating different (semi-)positivity properties of \( K_{X/T} \) have been been used extensively to solve standard conjectures in higher dimensional algebraic geometry in characteristic zero. Some examples are the following, where due to the huge number of references we only mention very few ones:

- subadditivity of Kodaira dimension (here there are particularly many references with the few initial ones being [Fuj78, Kaw81, Vie77, Vie83, Kol87]),
- construction of moduli spaces of \( K-/KSBA \)-stable varieties (e.g., [Vie89, KSB88, Fuj18, KP17, CP18, XZ19]),
- hyperbolicity questions (e.g., [VZ03, CHM97, Abr97]),
- non-vanishing conjecture (e.g., [Zha20]),
- geography of varieties (e.g, [CCJ20]),
- etc.

Motivated in part by the huge number of applications in characteristic zero, (semi-)positivity of the relative canonical bundle has been an active area of research in the past ten years also over algebraically closed fields \( k \) of characteristic \( p > 0 \). Some examples of the positive results are [Pat14, Pat18, CZ13, Eji19, EZ18, BCZ18]. The common aspect of these results is that extra conditions are needed compared to characteristic zero to exclude wild behavior in positive characteristics. For example, the \( F \)-singularity classes are needed to be used that exclude such bad arithmetic behavior, or when fixing the dimension one needs to exclude a few low primes. In particular, one would expect that the statement \((1.0.a)\) with assumption (Psef) fails in positive...
characteristic as this condition does not take into account wild behavior. In fact, recently the expectation of the failure of (1.0.a) with assumption (Psef) was confirmed by [CEKZ20].

On the other hand, assumptions (Psef) and (N-ur) of (1.0.a) are not equivalent in positive characteristic, and (N-ur) does take into account some of the typical wild behavior, see the introduction of [PZ20]. Hence, one could hope that statement (1.0.a) with condition (N-ur) still holds in positive characteristic, which is exactly our main theorem:

**Theorem 1.1.** (Smooth case of Theorem 4.3) Let $f : X \to T$ be a surjective morphism between smooth projective varieties over $k$ with integral and non-uniruled geometric generic fiber. Then $K_{X/T}$ is pseudo-effective.

Note that, Theorem 1.1 implies that the examples of [CEKZ20] need to have uniruled geometric generic fiber, and indeed they are (very) singular rational curves. Also, as indicated in the statement of Theorem 1.1, and as will be the case also for Theorem 1.3 and Corollary 1.4, we state a singular version in the latter parts of the article, allowing as bad singularities as the proof lets us do. This means complete intersection, $W\mathcal{O}$-rational, and $W\mathcal{O}$-rational and Cohen-Macaulay singularities in the three respective cases.

Our last remark concerning Theorem 1.1 is that the pseudo-effectivity of $K_{X/T}$ is one of the weakest possible semi-positivity property. For example, under the same assumption $f_\ast\omega_{X/T}$ is known to be not always semi-positive. In fact, there are examples of families $f : X \to T$ of smooth hyperbolic curves such that $f_\ast\omega_{X/T}$ is nef [MB81]. Nevertheless, from Theorem 1.1 it follows that even in this case, at least the weaker property holds that $K_{X/T}$ is pseudo-effective. In fact, similar phenomenon was known earlier: in [Pat14] it was shown that $K_{X/T}$ is nef as soon as it is $f$-nef and the fibers have mild singularities. The novelty of Theorem 1.1 is to weaken these assumptions to the almost most general case, at the price of also weakening the conclusion from being nef to being pseudo-effective. In fact, the only possible further generalization of Theorem 1.1 would be to remove the geometrically integral assumption, which we leave as an open question.

As usual for results as above, Theorem 1.1 implies the following subadditivity of Kodaira dimension type result, where we refer to the first paragraph of Section 4.2 for the definition of the canonical divisor of $X_\eta$ and for the fact that $K_{X_\eta} = K_X|_{X_\eta}$.

**Corollary 1.2.** If $f : X \to T$ is a surjective morphism between smooth projective varieties over $k$ such that $T$ is of general type and the geometric generic fiber $X_\eta$ is integral, non-uniruled with $K_{X_\eta}$ big, then

$$\kappa(X) \geq \kappa(K_{X_\eta}) + \kappa(T).$$

The hardest in the proof of Theorem 1.1 is to construct a smooth non-uniruled finite cover of $T$. Being in the situation of char $p > 0$ renders this hard in two aspects:

- It is hard to show that a variety is not uniruled.
- We need to use a construction that gives smoothness directly, as resolution of singularities is not available.

So, next we state the by-product statements we obtained while constructing this non-uniruled cover. The first one is a simple non-uniruledness condition, in terms of coherent cohomology. The author is in fact not aware of earlier such conditions in the literature that work for arbitrary varieties. However, before the statement we need to recall the notion of Frobenius-semistable part:

If $X$ is a projective variety over $k$, then the absolute Frobenius morphism $F : X \to X$ induces a homomorphism $F^* : H^i(X, \mathcal{O}_X) \to H^i(X, \mathcal{O}_X)$. This is referred to as the Frobenius action on $H^i(X, \mathcal{O}_X)$. The **semistable** part of $H^i(X, \mathcal{O}_X)$ with respect to this action can be defined multiple ways (e.g., [CL98, Lem 3.3]):

$$H^i(X, \mathcal{O}_X)^{ss} := \left( H^i(X, \mathcal{O}_X)^{F^* = \text{Id}} \right) \otimes_{\mathbb{F}_p} k = (F^*)^e \left( H^i(X, \mathcal{O}_X) \right)$$

for $e \gg 0$. 

**Theorem 1.3.** (Smooth case of Theorem 3.16) If for a smooth projective variety $X$ over $k$ of dimension $n > 0$ the inequality
\[
\dim_k H^{n-1}(X, \mathcal{O}_X)^{ss} < \dim_k H^n(X, \mathcal{O}_X)^{ss}
\]
holds, then $X$ is not uniruled.

The construction of the smooth non-uniruled cover of $T$ is then given by the following corollary of Theorem 1.3:

**Corollary 1.4.** (Smooth case of Theorem 3.21) Let $X$ be a smooth projective variety over $k$, let $\mathcal{H}$ be an ample line bundle on $X$. Then there exists an integer $s > 0$ with the following property: for every integer $p \mid d > 0$, and for every general $D \in |\mathcal{H}^{sd}|$, the corresponding degree $d$ cyclic cover
\[
Y := \text{Spec}_X \left( \bigoplus_{i=0}^{d-1} \mathcal{H}^{-si} \right)
\]
ния algebra structure given by $\mathcal{H}^{-sd} \cong \mathcal{O}_X(-D) \rightarrow \mathcal{O}_X$

is not uniruled for $s \gg 0$.

Lastly, we mention a direct consequence of Theorem 1.3 to mixed characteristic. The starting point is the fact that uniruledness is not a constructible property in mixed characteristic families. In fact, [Kol96, Thm IV.1.8.1] states that the locus in flat families, where fibers are uniruled is a countable union of closed subvarieties. And, over mixed characteristic bases that are finite type over $\mathbb{Z}$ this is the best on can say. For example, consider $X := V(x^4 + y^4 + z^4 + v^4 = 0) \subseteq \mathbb{P}^3_{\mathbb{Z}[1/2]}$. By [SK79, Thm III], $X_p$ is unirational and hence also uniruled whenever $p \equiv -1(4)$. On the other hand, if $p \equiv 1(4)$, then $X_p$ is globally $F$-split, as the coefficient of $xyzv^{p-1}$ in $(x^4 + y^4 + z^4 + v^4)^{p-1}$ is non-zero. Equivalently $X_p$ is weakly ordinary, and then for example [PZ20, Thm 1.1] implies that $X_p$ in this case is not uniruled. Hence, in this case both the uniruled and the non-uniruled locus is infinite, and they both have density $\frac{1}{2}$.

Summarizing, the above example shows that the constructibility of neither the uniruled, nor the non-uniruled locus holds. And in fact, both loci can be not only infinite, but even of high density. On the other hand the author is not aware of results pertaining to general varieties claiming that these infinite behaviors are not only possible, but they happen whenever certain criteria are satisfied. This seems to be an extremely hard problem, especially if one would also say something about densities. Nevertheless, Theorem 1.3 implies a statement of this type assuming the Weak ordinarity conjecture:

The **weakly ordinarity conjecture** [MS11, Conj 1.1] states that if $X_S \rightarrow S$ is a smooth, projective family over an integral, mixed characteristic base of finite type over $\text{Spec} \mathbb{Z}$ with generic point $\eta$, then the set
\[
\{ s \in S \text{ a closed point } | \dim_{k(s)} H^i(X_s, \mathcal{O}_{X_s})^{ss} = \dim_{k(\eta)} H^i(X_\eta, \mathcal{O}_{X_\eta}) \}
\]
is dense.

**Corollary 1.5.** Let $X$ be a smooth projective variety over a field $k_0$ of characteristic zero such that $\dim_{k_0} H^{\dim X}(X, \mathcal{O}_X) > \dim_{k_0} H^{\dim X-1}(X, \mathcal{O}_X)$, and let $X_S \rightarrow S$ be a model of $X$ over an integral, mixed characteristic base of finite type over $\text{Spec} \mathbb{Z}$. Then, assuming the weakly ordinarity conjecture, the following set is dense in $S$:
\[
\{ s \in S \text{ a closed point } | X_s \text{ is not uniruled} \}
\]

1.1. **The structure of the article and the outline of the proof**

The main idea of the proof of Theorem 1.1, or rather of its singular version Theorem 4.3, is relatively straightforward, and it is done in Section 4.2. We use a bend-and-break argument together with a base-change to a non-uniruled cover of the base, a few iterated Frobenius base-changes and the fact that by now it is known in any characteristic that the pseud-effective cone
is the dual of the cone of movable curves. We refer to the proof of Theorem 4.3 for the details, and here we only explain the main technical obstacle, which leads to the majority of the work done in the article: it is essential that during the above mentioned base-changes the total space of the fibration stays integral, and its singularities stay local complete intersections, so that bend-and-break applies. The only way we are able to guarantee this is if the base-changes are induced by finite flat covers of the base by smooth varieties.

Hence, the majority of article, that is, Section 3, is about showing the existence of a finite flat smooth non-uniruled cover for any smooth projective variety $X$ of dimension $n$. This is done by first showing in Theorem 3.16, which can be found in Section 3.2, and which states that if the inequality

\[(1.5.a) \quad H^{n-1}(X, \mathcal{O}_X)^{ss} < H^{n}(X, \mathcal{O}_X)^{ss}\]

holds, then $H^n(X, W\mathcal{O}_{X,Q}) \neq 0$. It has been known that this non-vanishing implies non-uniruledness in the case of $\mathcal{O}$-rational singularities [Esn03] [PZ20, Prop 4.6]. So, let us focus on how one shows the non-vanishing. By the definition of $H^n(X, W\mathcal{O}_{X,Q})$, it is equivalent to finding an element $x \in H^n(X, W\mathcal{O}_X)$ such that $p^i x \neq 0$ for every integer $i > 0$. The main idea to achieve this is to show that inequality (1.5.a) implies that the length of the semi-stable part $H^n(X, W_i\mathcal{O}_X)^{ss}$ is a strictly monotone function of $i$. Based on this realization we show in the proof of Theorem 3.16 that there is another strictly monotone sequence $j_i$ and compatible elements $x_{ij} \in H^n(X, W_j\mathcal{O}_X)^{ss}$ such that $p^i x_{ij} \neq 0$. The key here is to realize that $p^i = V^1 F^i$, so as $i \cdot \dim H^{n-1}(X, \mathcal{O}_X)$ gives an upper bound for the kernel of $V^i$ and as $F$ acts by bijection on $H^n(X, W_j\mathcal{O}_X)^{ss}$, we have plenty of elements $y \in H^n(X, W_j\mathcal{O}_X)^{ss}$ with $p^i y \neq 0$ as soon as we choose $j_i$ to be large enough. We refer for the finer details to the proof of Theorem 3.16. Instead we give two more general remarks:

(1) We think it is essential that we allow in the above argument $j_i$ to be much larger than $i$, that is, one cannot find always $x = (x_i) \in H^n(X, W\mathcal{O}_X) = \lim_{\rightarrow} H^n(X, W_i\mathcal{O}_X)$ such that $p^i x \neq 0$. Unfortunately, giving a precise example to such behavior is very hard, as it needs an example of a variety with Bockstein operators that are either injective or at least have very small kernel. So, we leave this as an open question. Nevertheless, we cannot exclude the existence of such varieties, and hence we are forced to allow $j_i$ to be much larger than $i$ in the proof of Theorem 3.16.

(2) The above argument needs a setup of some category into which $H^j(X, W_i\mathcal{O}_X)$ fits, which takes into account the Frobenius actions and hence using which one can talk about semi-stable submodules. This is a situation that resembles that of $F$-crystals, but instead of free $Wk$ modules we consider finite length $Wk$-modules. As we did not find a reference for this setting, we worked out the details in Section 3.1.

Finally, we have to show that a cyclic cover $Y$ of $X$ as in Corollary 1.4 (or as in the singular version in Theorem 3.21) satisfies condition (1.5.a). As for such covers $H^{n-1}(Y, \mathcal{O}_Y)$ is bounded, this boils down to showing that $\dim_k H^n(Y, \mathcal{O}_Y)^{ss}$ grows indefinitely for a general $D$. This then boils down to showing that the semi-stable subspace $H^n(X, H^{-s})^{ss,D}$ with respect to the following Frobenius action for general $D$ grows indefinitely as we increase $s$ (here $e > 0$ is an integer such that $d|p^e - 1$):

\[
\begin{align*}
\mathcal{H}^{-s} & \twoheadrightarrow \mathcal{H}^{-s} \otimes F^e_s \mathcal{O}_X \cong F^e_s \mathcal{H}^{-sp^e} \twoheadrightarrow \frac{P^{e+1} D}{\mathcal{F}^e_s \mathcal{H}^{-s}}.
\end{align*}
\]

It is not hard to show this for a specific choice of $D$ as soon as $\mathcal{H}^s$ is ample enough using the local description of the Frobenius trace, see the proof of Theorem 3.21 in Section 3.4. Then, we show in Proposition 3.20, which can be found in Section 3.3, that the statement deforms to the Frobenius action given by a general $D$.

1.2. Acknowledgement

The author is particularly grateful to Maciej Zdanowicz, from who he learned a big part of the Witt-Cohomology techniques used in Section 3 while working on their joint paper [PZ20],
and with whom he had multiple extremely useful conversations about the article. The author would like to thank in general the members of his group who were present at the group meetings when discussing the paper.

The author was partially supported by the following grants: grant #200021/169639 from the Swiss National Science Foundation, ERC Starting grant #804334.

2. Notation

As mentioned in the first line of the article, we fix an algebraically closed base-field $k$ of characteristic $p > 0$. In the present article, variety means a quasi-projective, integral scheme over $k$.

We use Witt-sheaves and Witt-cohomology in Section 3.1 and Section 3.2. For the notation concerning this we refer to [GNT15, Section 2.5].

Throughout the article generic fiber of a morphism $f : X \to T$ to an integral scheme is the fiber $X_\eta$ over the generic point $\eta = \text{Spec} K(T)$ of $T$. This is not to be confused with the general fiber of $f$, by which we mean the closed fibers over a non-empty open set of the base, assuming that $T$ is of finite type over $k$. In fact, the generic fiber typically behaves quite differently than the general fiber. On the other hand, the geometric generic fiber $X_\eta$ usually has a singularity behavior similar to that of the general fiber (e.g. [PW17, Prop 2.1]).

2.1. Local complete intersection singularities

We use the definition of [Sta] for local complete intersection singularities. The definition of when a morphism $f : X \to Y$ is local complete intersection is given in [Sta, Definition 069F], using Koszul-regularity. However, for locally Noetherian schemes this agrees with the usual definition that it factors as

$$
\begin{array}{c}
X \\
g
\downarrow \\
\downarrow \\
Z \\
h
\downarrow \\
Y
\end{array}
$$

where $h$ is smooth, and $g$ is a closed embedding defined locally by a regular sequence [Sta, Lemma 063L], [Sta, Definition 063J], [Sta, Definition 063D], [Sta, Definition 00LF].

If we specialize the above definition to $Y = \text{Spec} k$, then we obtain the notion of local complete intersection singularities. That is, $X$ has local complete intersection singularities, if locally around each $x \in X$, $X$ is a closed subscheme of a smooth variety $Z$, where the ideal of the embedding is generated by a regular sequence $f_i \in \mathcal{O}_{X,x}(i = 1, \ldots, r)$. Equivalently, one can require that $\dim_x X = \dim_x Z - r$ [Mat89, Thm 17.4].

**Proposition 2.1.**

1. If $f : X \to Y$ is a complete intersection morphism, and $Y$ has complete intersection singularities, then $X$ has also complete intersection singularities.
2. If $f : X \to Y$ is a morphism of finite type between regular Noetherian schemes, then $f$ is a complete intersection morphism.

**Proof.**

1. This is shown in [Sta, Lemma 069J].
2. By the finite type assumption, locally $f$ can be factored as

$$
\begin{array}{c}
X \\
g
\downarrow \\
\downarrow \\
\mathbb{A}_Y^n \\
h
\downarrow \\
Y
\end{array}
$$

where $g$ is a closed embedding. Applying [Sta, Lemma 0E9J] yields that $g$ locally is given by an ideal generated by a regular sequence.

We also note that complete intersection singularities are Cohen-Macaulay. So, if $X$ has complete intersection singularities, then $X$ being reduced is decided at the generic points of $X$.  

3. A Flat Non-Uniruled Smooth Cover

3.1. Category of $W_{k^\sigma}$-modules of finite $W_k$-length.

Here we present some foundational material, which might or might not be well-known for experts. The arguments and the ideas of the proofs in Section 3.1 are certainly well known for the experts. However, we did not find a reference for the main statement, that is, to Proposition 3.11. In particular, we include a detailed proof of Proposition 3.11, remarking that both the statement, and the proofs might be not unexpected for the experts.

The main reason for the existence of the present section is that we want to work with the cohomology groups $H^i(X, W_j \mathcal{O}_X)$, which are finite length $W_k$-modules with a Frobenius action, but they are not modules over $k$. The author of the article found in the literature only either works considering free $W_k$-modules with a Frobenius action ($F$-crystals) and $k$-modules with a Frobenius action (usual coherent cohomology). The case of finite length $W_k$-modules is in between these two cases.

Before we state the definition of our main objects, let us explain also two notational decisions:

- As usual in the theory of $F$-crystals, we also denote the Frobenius morphism on $W_k$ by $\sigma : W_k \to W_k$ to avoid mixing it up with the Frobenius action on our modules.
- To avoid the clash of notation with the theory of $F$-crystals, which concerns free $W_k$-modules, as explained above, we call our modules $W_{k^\sigma}$-modules.

Just for the definition of $W_{k^\sigma}$ modules we do not need to restrict to the case of finite length $W_k$.

This additional condition we will impose only later where it is necessary.

Definition 3.1. A $W_{k^\sigma}$-module is a pair $(M, F)$, such that $M$ is a $W_k$-module, and $F : M \to M$ is an additive homomorphism such that

$$(3.1.a) \quad \forall m \in M, \forall r \in W_k : F(rm) = \sigma(r)F(m).$$

A $W_{k^\sigma}$-submodule of a $W_{k^\sigma}$-module $M$ is a $W_k$-submodule $N \subseteq M$ such that $F(N) \subseteq N$.

Lemma 3.2. The action of $\sigma$ is invertible on $W_k$.

Proof. Using the presentation of [Ser79, Section II.6] or [GNT15, Section 2.5], the elements of $W_k$ can be thought of as vectors $(a_0, a_1, \ldots) \in k^n$, and the map $\sigma$ is given by $(a_0, a_1, \ldots) \mapsto (a_0^p, a_1^p, \ldots)$. As $k$ is perfect, this is bijective.

Notation 3.3. Let $X$ be a projective variety over $k$ of dimension $n$. We have ring homomorphisms

- $R : W_{j+1} \mathcal{O}_X \to W_j \mathcal{O}_X$,
- $V : W_j \mathcal{O}_X \to W_{j+1} \mathcal{O}_X$,
- $p : W_j \mathcal{O}_X \to W_j \mathcal{O}_X$, and
- $F : W_j \mathcal{O}_X \to W_j \mathcal{O}_X$.

Using the notation of [Ser79, Section II.6] or [GNT15, Section 2.5], these homomorphisms are given by

$R(a_0, \ldots, a_j) = (a_0, \ldots, a_{j-1}), \quad V(a_0, \ldots, a_{j-1}) = (0, a_0, \ldots, a_{j-1}),$

$F(a_0, \ldots, a_{j-1}) = \left(a_0^p, \ldots, a_{j-1}^p\right), \quad$ and $p(a_0, \ldots, a_{j-1}) = \left(0, a_0^p, \ldots, a_{j-2}^p\right)$.

In particular, we have the relations

$p = VF, \quad FV = VF, \quad pF = Fp, \quad$ and $Vp = pV.$

This then induces homomorphisms and also the respective relation after applying $H^i(X, _\cdot)$. By abuse of notation, we denote also these induced homomorphisms by $R, V, p$ and $F$.

Remark 3.4. Using Notation 3.3, the following properties will be important for us. Apart from the first one, these properties hold first on the ring level, and then consequently also after applying $H^i(X, _\cdot)$ by functoriality.

So, the properties are as follows, where $r \in W_k$ and $m \in H^i(W_j \mathcal{O}_X)$ are arbitrary:
(1) $F$ and $R$ are ring homomorphism before applying $H^i(X, \_)$,
(2) $F$, $V$, $R$ and $p$ are additive both before and after applying $H^i(X, \_)$,
(3) $F(r \cdot m) = \sigma(r) \cdot m$,
(4) $V(r \cdot m) = \sigma^{-1}(r) \cdot V(m)$, where $\sigma : Wk \to Wk$ is bijective by Lemma 3.2, and
(5) $p(r \cdot m) = r \cdot (pm)$.

**Lemma 3.5.** If $X$ is a projective variety over $k$ and $i \geq 0$ and $j \geq 1$ are integers, then $H^i(X, W_j O_X)$ is a $Wk_\sigma$-module with $F : H^i(X, W_j O_X) \to H^i(X, W_j O_X)$ being the structure homomorphism.

**Proof.** This follows from the identities of Remark 3.4. \hfill \Box

Additionally, we want to work for different compositions of the maps $F$, $V$, $p$, $R$ and the Bockstein operators. These are not always $Wk$-linear. This is the motivation for the notion of generalized $Wk_\sigma$-module homomorphism, defined in **Definition 3.6.**

**Definition 3.6.** Let $M$ and $N$ be $Wk_\sigma$-modules, and let $\alpha : M \to N$ be a map of sets. Then,

1. $\alpha$ is an **additive F-homomorphisms** if it is an additive homomorphism such that the following diagram commutes:

$$
\begin{array}{ccc}
M & \xrightarrow{\alpha} & N \\
\downarrow F & & \downarrow F \\
M & \xrightarrow{\alpha} & N
\end{array}
$$

2. $\alpha$ is a $Wk_\sigma$-homomorphism, if it is an additive $F$-homomorphism and a $Wk$-module homomorphism at once.

3. $\alpha$ is a **generalized $Wk_\sigma$-homomorphism**, if it is an additive $F$-homomorphism and there is an $i \in \mathbb{Z}$ such that for ever $r \in Wk$ the following diagram commutes:

$$
\begin{array}{ccc}
M & \xrightarrow{\alpha} & N \\
\downarrow x \mapsto r \cdot x & & \downarrow x \mapsto \sigma^i(r) \cdot x \\
M & \xrightarrow{\alpha} & N
\end{array}
$$

The integer $i$ is called the **index of $\alpha$**.

**Example 3.7.** According to Remark 3.4, any composition of the maps $F$, $V$, $R$ and $p$ on $H^i(X, W_j O_X)$ is a generalized $Wk_\sigma$-module homomorphism.

We draw attention to the fact that in the next proposition some statements are about $Wk$-modules and others are about $Wk_\sigma$-modules.

**Lemma 3.8.** Let $M$ and $N$ be $Wk_\sigma$-modules and let $\alpha : M \to N$ be a generalized $Wk_\sigma$-module homomorphism.

1. If $L \subseteq M$ is a $Wk$-submodule of $M$, then $\alpha(L)$ is a $Wk$-submodule of $N$.
2. If $L \subseteq N$ is a $Wk$-submodule of $N$, then $\alpha^{-1}(L)$ is a $Wk$-submodule of $M$.
3. $\ker \alpha$ is a $Wk_\sigma$-submodule of $M$.
4. $\text{im} \alpha$ is a $Wk_\sigma$-submodule of $N$.
5. $\text{coker} \alpha$ inherits a natural $Wk_\sigma$-module structure from $N$.
6. $\text{length}_{Wk} M - \text{length}_{Wk} \ker \alpha = \text{length}_{Wk} \text{im} \alpha$. (This is not obvious because according to Definition 3.6, $\alpha$ need not be a $Wk$-homomorphism)

**Proof.** Let $i$ be the index of $\alpha$, see point (3) of Definition 3.6.

1. As $\alpha$ is additive, $\alpha(L)$ is an additive subgroup of $N$. To see that it is in fact a $Wk$ submodule, choose $m \in L$ and $r \in Wk$. Then $r \cdot \alpha(m) = \alpha (\sigma^{-1}(r) \cdot m) \in \alpha(L)$.
2. Similarly, choose, $m \in \alpha^{-1}(L)$ and $r \in Wk$. Then $\alpha(r \cdot m) = \sigma^i(r) \cdot \alpha(m) \in L$, and hence $r \cdot m \in \alpha^{-1}(L)$. 

(3) \( \text{im} \alpha = \alpha(M) \) is a \( W_k \)-submodule by point (1). So, we only have to show that \( F(\text{im} \alpha) \subseteq \text{im} \alpha \). This follows from the commutative diagram (3.6.b).

(4) Similarly, \( \ker \alpha = \alpha^{-1}(0) \) is a \( W_k \)-submodule by point (2). So, we only have to show that \( F(\ker \alpha) \subseteq \ker \alpha \), which again follows from (3.6.b).

(5) By point (4), \( \text{im} \alpha \) is a \( W_k \)-submodule of \( M \), and hence \( \text{coker} \alpha \) inherits a natural \( W_k \)-module structure. Additionally \( F \)-also descends to \( \text{coker} \alpha \) as \( F(\text{im} \alpha) \subseteq \alpha \) holds also by point (4).

(6) Note that \( \alpha \) induces an additive bijection \( \tilde{\alpha} : M/\ker \alpha \rightarrow \text{im} \alpha \). Using that \( \alpha \) is a generalized \( W_{k_\sigma} \)-homomorphism, we see that so is \( \tilde{\alpha} \). The only reason we are not ready is that if the index is not zero, then \( \alpha \) might not be an actual \( W_k \)-module homomorphism. However, by points (1) and (2), the chains of submodules of \( M/\ker \alpha \) and \( \text{im} \alpha \) correspond to each other via \( \tilde{\alpha} \). This concludes our proof.

\[ \Box \]

**Lemma 3.9.** For every integer \( j > 0 \), length\(_{W_k} H^j(X, W_j O_X) \) if finite.

**Proof.** We prove by induction on \( j \). If \( j = 1 \), then \( W_j O_X = O_X \), and the statement follows straight from the projectivity of \( X \). For \( j > 1 \), consider the exact sequence

\[
(3.9.c) \quad H^j(X, O_X) \xrightarrow{V} H^j(X, W_j O_X) \xrightarrow{R} H^j(X, W_{j-1} O_X)
\]

According to Lemma 3.5 and Example 3.7, the modules and the maps of (3.9.c) are \( W_{k_\sigma} \)-modules and generalized \( W_{k_\sigma} \)-module homomorphisms. By the induction hypothesis their length over \( W_k \) is finite. Then Lemma 3.8 concludes our proof.

\[ \Box \]

**Definition 3.10.** For a \( W_{k_\sigma} \)-module \( M \) with length\(_{W_k} M \) finite, consider \( F^e(M) \subseteq M \), for every integer \( e > 0 \). Applying Lemma 3.8 with \( \alpha = F^e \), this gives a descending chain of \( W_{k_\sigma} \)-submodules of \( M \). As length\(_{W_k} M < \infty \), this chain stabilizes. Hence, we may define:

\[ M^{ss} := F^e(M), \text{ for } e \gg 0. \]

Note: by point (4) of Lemma 3.8, \( M^{ss} \) is a \( W_{k_\sigma} \)-submodule.

**Proposition 3.11.** Let \( \mathcal{C} \) be the category of finite \( W_k \)-length \( W_{k_\sigma} \)-modules with arrows being the generalized \( W_{k_\sigma} \)-module homomorphisms. Then:

(1) For any arrow \( \alpha \) in \( \mathcal{C} \), \( \ker \alpha \), \( \text{im} \alpha \) and \( \text{coker} \alpha \) are also in \( \mathcal{C} \) (here \( \ker \alpha \), \( \text{im} \alpha \) and \( \text{coker} \alpha \) are taken as for additive groups and then they are endowed with a \( W_{k_\sigma} \)-module structure using Lemma 3.8).

(2) \( \alpha : M \rightarrow M^{ss} \) is an exact functor \( \mathcal{C} \rightarrow \mathcal{C} \),

(3) length\(_{W_k} (\_ \_ \_ \_ \_ \_ \_) \) is additive in exact sequences in \( \mathcal{C} \).

**Remark 3.12.** The category \( \mathcal{C} \) of Proposition 3.11 has somewhat unusual properties too, which are not mentioned in Proposition 3.11. This is due to allowing generalized \( W_{k_\sigma} \)-module homomorphisms of different indices into the category. The main issue is that it is not possible to add homomorphisms with different indices, or to construct homomorphisms to products induced by component homomorphisms of different indices. Therefore, \( \mathcal{C} \) is not abelian and it does not have products. One can solve this by disallowing generalized \( W_{k_\sigma} \)-homomorphisms and introducing instead a notion of twist of the objects (i.e., twisting the \( W_{k_\sigma} \)-structure by an adequate power of \( \sigma \)). This way one can turn every commutative diagram in \( \mathcal{C} \) into a commutative diagram in this more restrictive category by adequately twisting the modules. To avoid writing twists in each diagram, we chose the first approach.

We prove Proposition 3.11 after a few more lemmas.

**Lemma 3.13.** Let \( M \) and \( N \) be two \( W_{k_\sigma} \)-modules, and let \( \alpha : M \rightarrow N \) be an additive \( F \)-homomorphism. Then:

(1) \( F|_{M^{ss}} \) is an isomorphism,

(2) \( \alpha(M^{ss}) \subseteq M^{ss} \),

(3) if \( \alpha \) is surjective, then \( \alpha(M^{ss}) = M^{ss} \).
Proof. (1) Fix an $e > 0$ such that $F^e(M) = F^{e'}(M)$ for every $e' \geq e$. Then: $F|_{F^e(M)} : F^e(M) \to F^{e+1}(M) = F^e(M)$ is surjective. Now, point (6) of Lemma 3.8 shows that $\text{length} = \text{ker} (F|_{F^e(M)}) = 0$, that is, $F|_{F^e(M)}$ is bijective.

(2) Diagram (3.6.b) yields the following commutative diagram:

\[
\begin{array}{ccc}
M & \xrightarrow{\alpha} & N \\
\downarrow{F^e} & & \downarrow{F^e} \\
M & \xrightarrow{\alpha} & N
\end{array}
\]

The statement of the present point then follows directly from diagram (3.13.d).

(3) Follows also from (3.13.d), taking into account that $\alpha$ is surjective.

\[\square\]

Remark 3.14. Point (2) of Lemma 3.13 implies that if $\alpha : M \to N$ is a generalized $Wk_{\sigma}$-module homomorphism, then there is an induced generalized $Wk_{\sigma}$-module $\alpha^{ss} : M^{ss} \to N^{ss}$ homomorphism.

Lemma 3.15. Consider an exact sequence of $Wk_{\sigma}$ modules of finite $Wk$-length with arrows being generalized $Wk_{\sigma}$-module homomorphisms:

\[
0 \longrightarrow M \xrightarrow{\alpha} N \xrightarrow{\beta} L \longrightarrow 0
\]

Then

\[
0 \longrightarrow M^{ss} \xrightarrow{\alpha^{ss}} N^{ss} \xrightarrow{\beta^{ss}} L^{ss} \longrightarrow 0
\]

is exact.

Proof. According to point (3) of Lemma 3.13 we only have to show that $\text{ker} \beta^{ss} = \text{im} \alpha^{ss}$. This is equivalent to showing that $\alpha(M^{ss}) = N^{ss} \cap \text{ker} \beta$, which is further equivalent to $(\text{ker} \beta)^{ss} = N^{ss} \cap \text{ker} \beta$. We prove this latest one. As $(\text{ker} \beta)^{ss}$ is contained both in $N^{ss}$ and $\text{ker} \beta$, we have $(\text{ker} \beta)^{ss} \subseteq N^{ss} \cap \text{ker} \beta$. So, we have to only show the opposite containment, for which it is enough to show that $F|_{N^{ss} \cap \text{ker} \beta}$ is bijective.

We note at this point that as both $\text{ker} \beta$ and $N^{ss}$ are $Wk_{\sigma}$ submodules of $N$, so is $N^{ss} \cap \text{ker} \beta$. In particular, $F|_{N^{ss} \cap \text{ker} \beta}$ is a generalized $Wk_{\sigma}$-module endomorphism of $N^{ss} \cap \text{ker} \beta$. Additionally, by point (1) of Lemma 3.13, $F|_{N^{ss}}$ is injective. So, we obtain that $F|_{N^{ss} \cap \text{ker} \beta}$ is an injective generalized $Wk_{\sigma}$-module endomorphism of $N^{ss} \cap \text{ker} \beta$. Point (6) of Lemma 3.8 then shows that this endomorphism has to be in fact surjective, and hence a bijection.

\[\square\]

Proof of Proposition 3.11. Point (1) is shown in Lemma 3.8. Point (2) is shown in Remark 3.14 and Lemma 3.15. Point (3) is shown in point (6) of Lemma 3.8.

\[\square\]

3.2. Witt non-vanishing criterion

Theorem 3.16. If for a projective variety $X$ over $k$ of dimension $n > 0$, the inequality

\[(3.16.a) \quad \dim_k H^{n-1}(X, O_X)^{ss} < \dim_k H^n(X, O_X)^{ss},\]

holds, then $H^n(X, WO_X, \mathbb{Z}) \neq 0$.

In particular, if $X$ additionally is normal and it has $WO$-rational singularities (e.g., $X$ is smooth), then $X$ is not uniruled.

Proof. The addendum follows directly from [PZ20, Prop 4.6]. So, we only show the statement that $H^n(X, WO_X) \neq 0$.

Throughout the rest of the proof, all our cohomology groups are in the category $C$ of Proposition 3.11, except a one time mention of $H^n(X, WO_X)$. In particular, we will use the statements of Proposition 3.11, without each time explicitly indicating a reference to Proposition 3.11.
\textbf{Step 0: Initial setup.} Set
\[ r := \dim_k H^n(X, \mathcal{O}_X)^{ss} = \text{length}_{W_k} H^n(X, \mathcal{O}_X)^{ss}. \]

It is enough to exhibit
\[ x = (x_j) \in H^n(X, \mathcal{O}_X) = \lim H^n(X, W_j \mathcal{O}_X), \]
such that:
\[ (3.16.b) \quad \forall i \geq 1 : \ p^i x \neq 0 \iff \forall i \geq 1 \ \exists j_i > 0 : \ p^i x_{j_i} \neq 0. \]
So, our goal is to exhibit \( x_{j_i} \) as above satisfying the second equivalent condition of (3.16.b). We will do this by induction on \( i \), and we will choose \( x_{j_i} \) such that \( x_{j_i} \in H^n(X, W_j \mathcal{O}_X)^{ss} \).

\textbf{Step 1: Semistable subspace grows indefinitely.} Consider for any integer \( j \geq 0 \) the exact sequence:

\[
H^{n-1}(X, \mathcal{O}_X) \xrightarrow{B} H^n(X, \mathcal{O}_X) \xrightarrow{V} H^n(X, W_{j+1} \mathcal{O}_X) \xrightarrow{R} H^n(X, W_j \mathcal{O}_X) \to 0
\]

By taking the semi-stable subspace, we obtain another exact sequence:

\[
H^{n-1}(X, \mathcal{O}_X)^{ss} \xrightarrow{B^{ss}} H^n(X, \mathcal{O}_X)^{ss} \xrightarrow{V^{ss}} H^n(X, W_{j+1} \mathcal{O}_X)^{ss} \xrightarrow{R^{ss}} H^n(X, W_j \mathcal{O}_X)^{ss} \to 0
\]

By taking \( \text{length}_{W_k}(\_) \), and using (3.16.a) we obtain that
\[ (3.16.d) \quad \text{length}_{W_k} H^n(X, W_{j+1} \mathcal{O}_X)^{ss} > \text{length}_{W_k} H^n(X, W_j \mathcal{O}_X)^{ss} \implies \text{length}_{W_k} H^n(X, W_j \mathcal{O}_X)^{ss} \geq j. \]

\textbf{Step 2: Surjectivity of \( R^{ss} \).} \( H^n(X, W_{j+1} \mathcal{O}_X)^{ss} \to H^n(X, W_j \mathcal{O}_X)^{ss} \) is surjective. This follows from (3.16.d) being an exact functor and that \( H^n(X, W_{j+1}(\mathcal{O}_X) \to H^n(X, W_j \mathcal{O}_X) \) is surjective.

\textbf{Step 3: Starting the induction.} As \( H^n(X, \mathcal{O}_X) \neq 0 \) by (3.16.a), we may set \( j_0 := 1 \) and we may choose \( x_{j_0} \in H^n(X, \mathcal{O}_X) \) to be any non-zero element.

\textbf{Step 4: Induction step, initial setup.} So, fix an integer \( i > 0 \), and assume that \( x_{j_{i-1}} \in H^n(X, W_{j_{i-1}} \mathcal{O}_X)^{ss} \) is chosen. In particular, we have \( p^{t-1} x_{j_{i-1}} \neq 0 \). We have to choose \( j_i > j_{i-1} \), and \( x_{j_i} \in H^n(X, W_j \mathcal{O}_X)^{ss} \) such that \( R_{j_i-j_{i-1}} \circ x_{j_{i-1}} = x_{j_i} \) and \( p^i x_{j_i} \neq 0 \).

Consider now for any integer \( t > j_{i-1} \) the diagram

\[
\begin{array}{cccccc}
0 & \xrightarrow{0} & W_t \mathcal{O}_X & \xrightarrow{V} & W_{t+1} \mathcal{O}_X & \xrightarrow{R} & W_t \mathcal{O}_X & \to 0
\end{array}
\]

Taking cohomology and then semi-stable subspace we obtain

\[ (3.16.e) \quad H^{n-1}(X, W_t \mathcal{O}_X)^{ss} \xrightarrow{B_{tt}} H^n(X, W_t \mathcal{O}_X)^{ss} \xrightarrow{V_{tt}} H^n(X, W_{t+t} \mathcal{O}_X)^{ss} \]

According to (3.16.d), we may choose \( t > j_{i-1} \), such that \( Z := \text{Ker} \alpha \not\subseteq \text{im} B_{tt}^{ss} =: M \), where \( \alpha \) is the homomorphism \((R^{j_i-j_{i-1}})^{ss} : H^n(X, W_t \mathcal{O}_X)^{ss} \to H^n(X, W_{j_i} \mathcal{O}_X)^{ss}\). Fix this value of \( t \), and set \( j_i := t + i \).

\textbf{Step 5: We claim that} \( \alpha^{-1}(x_{j_{i-1}}) \not\subseteq M \). Indeed, assume the opposite, that is, that \( \alpha^{-1}(x_{j_{i-1}}) \subseteq M \). By Step 2, there is \( z \in \alpha^{-1}(x_{j_{i-1}}) \). Hence, we have \( Z + z = \alpha^{-1}(x_{j_{i-1}}) \), and then \( \bar{Z} + z \subseteq M \). Using the fact that \( M \) is additively closed, we have then the implications: \( z \in M \implies -z \in M \implies -z + (z + Z) = Z \subseteq M \). This contradicts the choice of \( t \) made in Step 4.

\textbf{Step 6: Concluding the induction step.} By Step 5, we may choose \( z' \in \alpha^{-1}(x_{j_{i-1}}) \setminus M \). In particular, as \( M \) is the image of the left-side map of the exact sequence in (3.16.e), we obtain that \( V^i(z') \neq 0 \). Choose now \( x_{j_i} \) to be any element of \( H^n(X, W_{j_i} \mathcal{O}_X)^{ss} \) mapping to \( z' \). By Step 2, this is possible. Additionally, as \( V^i(z') \neq 0 \), we have

\[
p^i x_{j_i} = F^i V^i R^i (x_{j_i}) = F^i V^i(z') \neq 0
\]

\( \square \)
3.3. Deformation of (Frobenius) semi-stable subspaces

Recall the following way of defining different Frobenius actions on a fixed line bundle: let \( L \) be a line bundle on a projective scheme \( X \) over \( k \) of dimension \( n \), let \( p \nmid d \) be an integer and let \( D \in |L^d| \) a divisor. Fix also an integer \( e > 0 \) such that \( d|p^e - 1 \). Then, one may define a Frobenius action induced by \( D \) on \( L^{-1} \) given by the following composition:

\[
\eta_{L,D} \quad L^{-1} \rightarrow L^{-1} \otimes F^e_*\mathcal{O}_X \cong F^e_*\mathcal{E} \cong F^e_*L^{-1} \cong F^e_*L^{-p^e} \quad \xrightarrow{\text{projection formula}} \quad F^e_*L^{-1}
\]

Applying \( H^n(X,\_\_ ) \) to this composition we obtain a \( p^e \)-linear action \( \psi_{L,D} \) on \( H^n(X,L^{-1}) \). We denote by \( H^n(X,L^{-1})^{ss,D} \) the semi-stable part with respect to \( \psi_{L,D} \), that is, the image of high enough iteration of \( \psi_{L,D} \). We suppressed the integer \( e \) from the notation of the semi-stable part, as it is an elementary exercise to see that the action is independent of the choice of \( e \) up to passing to a divisible enough iteration.

Recall that a perfect point \( y \) of a scheme \( Y \) is a morphism \( \text{Spec} L \rightarrow Y \) such that \( L \) is a perfect field.

**Lemma 3.17.** Let \( \mathcal{E} \) be a locally free sheaf of finite rank over a Noetherian integral scheme \( Y \), and let \( \mathcal{F} \subseteq \mathcal{E} \) be a coherent subsheaf. Then for every \( y \in Y \):

\[
\text{rk} \mathcal{F} \geq \dim_{k(y)} \text{im} \left( \mathcal{F} \otimes k(y) \rightarrow \mathcal{E} \otimes k(y) \right).
\]

**Proof.** Set \( I := \text{im} \left( \mathcal{F} \otimes k(y) \rightarrow \mathcal{E} \otimes k(y) \right) \), and set \( r := \dim_{k(y)} I \). We are supposed to show that \( \text{rk} \mathcal{F} \geq r \). We have

\[
\dim_{k(y)} \left( k(y) \otimes \left( \mathcal{E}/\mathcal{F}_y \right) \right) = \dim_{k(y)} \left( \mathcal{E} \otimes k(y) \right) - \dim_{k(y)} I = \text{rk} \mathcal{E} - r
\]

Since \( \mathcal{E} \) is locally free, \( \mathcal{E} / \mathcal{F}_y \) is a constant function of \( y \).

Hence, if \( \eta \) is the generic point of \( Y \), then the following computation concludes our proof:

\[
\text{rk} \mathcal{E} - \text{rk} \mathcal{F} = \text{rk} \left( \mathcal{E}_\eta / \mathcal{F}_\eta \right) = \dim_{k(\eta)} \left( k(\eta) \otimes \left( \mathcal{E}_\eta / \mathcal{F}_\eta \right) \right) \leq \dim_{k(y)} \left( k(y) \otimes \left( \mathcal{E}_y / \mathcal{F}_y \right) \right) = \text{rk} \mathcal{E} - r
\]

\[\left[ \text{Har77, Exc II.5.8} \right] \quad (3.17.b) \]

**Proposition 3.18.** Consider the following situation.

1. \( f : X \rightarrow Y \) is a projective, flat, Gorenstein morphism between varieties over \( k \) with geometrically integral fibers of dimension \( n \),
2. \( L \) is a line bundle on \( X \), such that \( \dim_{k(y)} H^n (X_y, L_y^{-1}) \) is a constant function of \( y \in Y \),
3. \( d > 0 \) is an integer such that \( p \nmid d \),
4. \( D \) is an effective divisor on \( X \), not containing any fiber, such that \( \mathcal{O}_X(D) \cong L^s \), and
5. for some perfect point \( y_0 \in Y \), we have \( l := \dim_{k(y_0)} H^n (X_{y_0}, L_{y_0}^{-1})^{ss,D_{y_0}} > 0 \).

Then, there is a non-empty open set \( U \subseteq Y \), such that \( \dim_{k(y)} H^n (X_y, L_y^{-1})^{ss,D_y} \geq l \) for every perfect point \( y \in U \).

**Proof.** The main technical difficulty in proving Proposition 3.18 is that one needs to work with a relative version of the Frobenius morphism. I.e. one needs a morphism that restricts on each (perfect) fiber to the Frobenius morphism of the corresponding fiber. This morphism is called the relative Frobenius morphism of \( f \), and it exists only after an adequate iterated Frobenius base-change. Additionally the depth of this base-change depends on the considered iteration of the Frobenius action on the fibers. Keeping track of these base-changes is notationally somewhat burdensome.
So, we have to work with Frobenius pullbacks of the base. Hence we adopt the following notation:

- Choose an integer $e > 0$ such that $d|p^e - 1$.
- Set $r := \frac{p^e - 1}{d}$.
- Since the statement is local, we may assume that $Y$ is affine and regular, with $A = \Gamma(Y, \mathcal{O}_Y)$.
- Set $\phi := F^e$, $A_i := A^{1/p^e} = F^e_i A$. In fact, by abuse of notation, we will use $\phi$ for $F^e_S$, where $S$ is any of the schemes appearing in the proof.
- Let $\xi$ be the natural morphism $A \to A_1$ sending $x$ to $x = (x^{1/p^e})^{p^e}$.

Consider the following commutative diagram of relative Frobenius of $f$, where we used the commutative algebra notation on the right side and the algebraic geometry notation on the left side. In fact, as all considered schemes are finite inseparable over $X$, diagram (3.18.c) contains the pushforwards to $X$ of the structure sheaves of the considered spaces, instead of the spaces themselves. Also note that for the whole proof pushforward is understood to have higher priority in the order of operations than tensor product.

The notable feature of diagram (3.18.c) is the following:

For any perfect point $y \in Y$ (or equivalently a non-zero $k$-algebra homomorphism $A \to L =: k(y)$, where $L$ is a perfect field), by restricting (3.18.c) to $y^{1/p^e}$ (or equivalently by applying $(\_ ) \otimes_{A_1} A^{1/p^e} k(y)^{1/p^e}$) we obtain the iterated relative Frobenius of $X_y$, and then by the perfectness of $k(y)$ we may identify these morphisms with the iterated absolute Frobenius of $X_y$.

Tensor now the left side of (3.18.c) by $L^{-1}$ over $A$. Using a considerable amount of projection formulas together with the fact that $\phi^*L^{-1} \cong L^{-p^e}$ we obtain the following commutative
diagram, where we define $\zeta : L^{-1} \otimes_A A_1 \rightarrow \phi_* L^{-p^e}$ by $\zeta := \xi \otimes_A L^{-1}$.

\[(3.18.e)\]

\[
\begin{array}{cccccc}
L^{-1} \otimes_A A_s \\
\downarrow \zeta \otimes_A A_s \\
\phi_* L^{-p^e} \otimes_A A_s = \phi_* (L^{-p^e} \otimes_A A_{s-1}) \\
\downarrow \\
\phi_* \zeta \otimes_A A_{s-1} = \phi_* (\zeta \otimes_A A_{s-1}) \\
\downarrow \\
\phi_*^{s-2} \zeta \otimes_A A_{s-2} = \phi_*^{s-2} (\zeta \otimes_A A_2) \\
\downarrow \\
\phi_*^{s-1} L^{-p^{(s-1)e}} \otimes A_{s-1} = \phi_*^{s-1} \left( L^{-p^{(s-1)e}} \otimes A_1 \right) \\
\downarrow \\
\phi_*^{s-1} \zeta \\
\phi_*^{s} L^{-p^e}
\end{array}
\]

Modify now (3.18.e) so that after each homomorphism we apply multiplication by $rD$ (after applying also adequate $\phi_*^i$ and $(\_ \otimes_A A_s)$. This way we obtain the following diagram, where $\eta$ is the composition of $\zeta$ with multiplication by $rD_A$:

\[(3.18.f)\]

\[
\begin{array}{cccccc}
L^{-1} \otimes_A A_s \\
\downarrow \eta \otimes_A A_s \\
\phi_* L^{-1} \otimes A_s = \phi_* \left( L^{-1} \otimes A_{s-1} \right) \\
\downarrow \\
\phi_* \eta \otimes_A A_{s-1} = \phi_* (\eta \otimes_A A_{s-1}) \\
\downarrow \\
\phi_*^{s-2} \eta \otimes_A A_{s-2} = \phi_*^{s-2} (\eta \otimes_A A_2) \\
\downarrow \\
\phi_*^{s-1} L^{-1} \otimes A_{s-1} = \phi_*^{s-1} \left( L^{-1} \otimes A_1 \right) \\
\downarrow \\
\phi_*^{s-1} \eta \\
\phi_*^{s} L^{-1}
\end{array}
\]

Using the notations of (3.18.d) we obtain:

\[(3.18.g)\]

the restriction of the homomorphisms of (3.18.f) over $y$ can be identified with the iterations of $\eta_{L_y} D_y$.

Apply now $R^n f_*(\_)$ to (3.18.f). Noting that as $n$ is the dimension of all fibers of $f$, in this situation $R^n f_*(\_)$ commutes with arbitrary base-change for coherent sheaves flat over $Y$. Hence,
if we define $E := R^n f_* L^{-1}$, then we obtain for every integer $0 \leq s$:
\begin{equation}
(3.18.h) \quad R^n f_* (\phi^i_* L^{-1} \otimes_{A_i} A_s) \cong R^n f_* (\phi^i_* (L^{-1} \otimes_A A_{s-i}))
\end{equation}

$\uparrow$

\begin{equation}
\phi^s \circ \phi^{s-i} \circ R^n f_* L^{-1} = \phi^s \circ \phi^{s-i} \circ E
\end{equation}

$R^n f_*(\underline{\cdot})$ commutes with arbitrary base-change for coherent sheaves flat over $\mathcal{Y}$.

Similarly, by defining $\psi = R^n f_*(\eta)$, we obtain for every integer $0 \leq i \leq s - 1$:
\begin{equation}
(3.18.i) \quad R^n f_* \phi^i_* (\eta \otimes_{A_i} A_{s-i}) = \phi^s \circ \phi^{s-i} \circ (R^n f_* (\eta)) = \phi^s \circ \phi^{s-i} \circ (\psi).
\end{equation}

Combining (3.18.f), (3.18.h) and (3.18.i), and disregarding the $\phi^s$, we obtain the following commutative diagram:
\begin{equation}
(3.18.j) \quad \phi^s \circ E \quad \phi^{s-1} \circ E \quad \phi^{s-2} \circ E \quad \ldots \quad \phi^1 \circ E \quad \phi^0 \circ E \quad \psi \circ E \quad \psi \circ E
\end{equation}

Using the notation of (3.18.d) and (3.18.g), as $R^n f_*(\underline{\cdot})$ commutes with arbitrary base-change, we see that:
\begin{equation}
(3.18.k) \quad \text{The restriction of the homomorphisms of } (3.18.j) \text{ over } y \text{ can be identified with the iterations } \psi_{L_y,D_y}.
\end{equation}

However, a warning should be given here: (3.18.k) does not mean that $(\text{im } \psi_y) \otimes k(y) = \text{im } \psi_{L_y,D_y}$, where $\psi_{L_y,D_y}$ is defined in (3.18.a). In fact, we have
\begin{equation}
(3.18.l) \quad \text{im } (\psi_{L_y,D_y})^s = \text{im } (\text{im } \psi^s) \otimes k(y) \to E \otimes k(y) \cong H^n (X_y, L_y^{-1})
\end{equation}

Note now that assumption (2) implies that $E$ is locally free. Consider then (3.18.l) for the special case of $y = y_0$. By assumption (5) and by Lemma 3.17 we obtain that $\text{rk } \text{im } \psi^s \geq l$. In particular, as $\text{rk } \text{im } \psi^s$ is a monotone decreasing function of $s$, there is an integer $t$ such that $\text{rk } \text{im } \psi^s$ is the same positive number for every $s \geq t$. Note that by assumption (5) this number is at least 1.

We claim the following disjointness of subsheaves of $\phi^{s-i} \circ E$:
\begin{equation}
(3.18.m) \quad (\phi^{t,s} \text{ im } \psi^t) \cap \text{ker } \psi^t = 0.
\end{equation}

Indeed, if the intersection was not zero, then as $E$ is locally free, the intersection would have positive rank, and hence im $\psi^{2t} = \psi^t (\phi^{s-i} \text{ im } \psi^t)$ would have rank smaller than that of $\text{im } \psi^t$. This is impossible by the choice of $t$, showing (3.18.m).

Equation (3.18.m) implies that $\psi_{|\phi^{s-i} \text{ im } \psi^t} : \phi^{s-i} \text{ im } \psi^t \to \psi^t$ is an isomorphism. Hence, for any integer $j > 0$ we have $\text{im } \psi^{jt} = \psi^t$. Additionally, by shrinking $Y$ we may assume that both $\text{im } \psi^t$ and $E/\text{im } \psi^t$ are locally free. In particular, for all $y \in Y$, $(\text{im } \psi^t) \otimes k(y) \to E \otimes k(y)$ is an injection. Then (3.18.l) shows that for every integer $j > 0$, we have $\text{dim } k(y) (\psi_{L_y,D_y})^t = \text{rk } \text{im } \psi^t \geq l$. This concludes our proof. □

3.4. Non-vanishing of a specific Frobenius action

Remark 3.19. In what follows it will be essential the following fact: if $X$ is any variety and $x \in X_{reg}$ is a closed point and $t_1, \ldots, t_n$ is a system of regular parameters at $x$, then the trace homomorphism $\text{Tr}_{F_*} : F_* \omega_X \to \omega_X$ can be identified in the formal neighborhood of $x$ with the following:
\begin{equation}
F_* k[x_1, \ldots, x_n] \cong \prod_{i=1}^n x_i^{j_i} \mapsto \begin{cases} 
\prod_{i=1}^n x_i^{j_i - p^e - 1} & \text{if } p^e \mid j_i - p^e - 1 \quad (\forall i) \\
0 & \text{otherwise}
\end{cases}
\end{equation}
Proposition 3.20. Let $X$ be a projective $S_2$ variety of dimension $n$, and let $\mathcal{H}$ be an ample line bundle and let $l > 0$ be an integer. Then, for every integer $s \gg 0$ the following holds: for any integer $p \mid d > 0$ and for general $D \in |\mathcal{H}^d|$, we have $\dim_k \mathcal{H}^n(X, \mathcal{H}^{-s})_{\text{ss}, D} \geq l$.

Proof. Choose an integer $e > 0$ such that $d/p^e - 1$, and set $r := \frac{p^e - 1}{n}$.

According to Proposition 3.18, we only have to exhibit a single $D$ as above. Additionally, with this single $D$ we can show that the Serre-dual action has at least $l$ dimensional semi-stable part. Additionally in degree 0 and $n$ Serre duality works for $S_2$ varieties by the proof of [PZ20, Prop 2.4]. Hence, we need to show that the following action on $\mathcal{H}^0(X, \omega_X \otimes \mathcal{H}^s)$ has at least $l$-dimensional semi-stable part:

(3.20.a) \[ H^0(X, \omega_X \otimes \mathcal{H}^s) \xrightarrow{\cdot D} H^0(X, \omega_X \otimes \mathcal{H}^{sp^e}) \cong H^0(X, \mathcal{H}^s \otimes F_{e}^{s} \omega_X) \xrightarrow{H^0(X, \text{TrF}_{e} \otimes \text{Id}_{\mathcal{H}^s})} H^0(X, \omega_X \otimes \mathcal{H}^s) \]

Fix pairwise distinct closed points $x_1, \ldots, x_l \in X_{\text{reg}}$. For each $1 \leq j \leq l$ let

\[ \{t_{i,j} \in m_{X,x_i} | i = 1, \ldots, n, j = 1, \ldots, l\} \]

be a regular system of parameters, and define the ideals $I_j := (\prod_{i=1}^{n} t_{i,j}) \cdot O_{X,x} \subseteq O_{X,x}$. After this, choose an integer $s \gg 0$ such that the following properties are satisfied:

- for all $1 \leq j \leq l$ there are sections $g_j \in H^0(X, \omega_X \otimes \mathcal{H}^s)$ such that

(3.20.b) \[ (g_j) \otimes k(x_{j'}) = \begin{cases} 1 & \text{if } j = j' \\ 0 & \text{otherwise} \end{cases} \]

- there is an $h \in H^0(X, \mathcal{H}^s)$ such that for all $1 \leq j \leq l$ we have $h_{x_j} \in I_j \setminus (I_j \cdot m_{X,x_j})$.

Let $\Gamma \in |\mathcal{H}^s|$ be the divisor corresponding to $h$, and set $D := d\Gamma$. The main point is that if we apply the action of (3.20.a) to $g_j$, then by the above choice of $D$, this is the same as applying the trace (or more precisely $H^0(X, \text{TrF}_{e} \otimes \text{Id}_{\mathcal{H}^s})$) to $g_j \cdot h^{p^e-1}$. As

\[ (g_j \cdot h^{p^e-1})_{x_j} \in \begin{cases} I^e_{j-1} \setminus I^e_{j-1} \cdot m_{X,x_j} & \text{if } j' = j \\ I^e_{j-1} \cdot m_{X,x_j} & \text{otherwise} \end{cases} \]

using Remark 3.19 it follows that trace takes $g_j \cdot h^{p^e-1}$ to a section that also satisfies the property (3.20.b). In particular, the same holds for the image of $g_j$ via the action of (3.20.a).

Iterating this argument we obtain that after iterating the action of (3.20.a) arbitrary many times for every $1 \leq j \leq l$ there will be a section in the image that is non-zero at $x_j$ and it is zero at $x_{j'}$ for every $j \neq j'$. This shows that the image is at least $l$-dimensional after arbitrary many iterations, concluding our proof.

\[ \square \]

3.5. General cyclic covers

Theorem 3.21. Let $X$ be a projective, $S_3$ variety of dimension $n$ over $k$, let $\mathcal{H}$ be an ample line bundle on $X$. Then for every integer $s \gg 0$ the following property: for every integer $p \mid d > 0$, and for every general $D \in |\mathcal{H}^d|$, if $Y$ is the corresponding degree $d$ cyclic cover, then $H^n(Y, O_{Y,Q}) \neq 0$.

If additionally $X$ is normal and $Y$ has W0-rational singularities, then $Y$ is not uniruled for $s \gg 0$.

Proof. Let $\pi : Y \to X$ be the considered cyclic cover. Then, we have $\pi_* O_Y \cong \bigoplus_{j=0}^{l} \mathcal{H}^{-js}$, and as $D$ is general $Y$ is normal. By the proof of [PZ20, Prop 2.4], in degree 1 and $n-1$ Serre duality works for $S_3$ varieties. Pairing this up with Serre vanishing we obtain that for every $s \gg 0$, we have $H^{n-1}(X, \mathcal{H}^{-sj}) = 0$ for every integer $j > 0$. Hence, for every integer $s \gg 0$, we have $H^{n-1}(Y, O_Y) = H^{n-1}(X, O_Y)$. In particular, according to Theorem 3.16, it is enough to show that for any integer $l > 0$, for every integer $s \gg 0$ we have $H^n(Y, O_Y)^{s, l}$, for choices of $d$
and D as in the statement of the theorem. However, it is easy to see that

$$H^n(Y, \mathcal{O}_Y)^{ss} = H^n(X, \mathcal{O}_X)^{ss} \oplus \left( \bigoplus_{j=1}^{d-1} H^n(X, \mathcal{H}^{-sj})^{ss, D} \right).$$

So, we are done by Proposition 3.20.

In Theorem 3.21 it is expected that it is enough to assume that $X$ has $\mathcal{W}$-rational singularities. The corresponding questions are the following:

**Question 3.22.** If $X$ is a $\mathcal{W}$-rational variety over $k$, then

1. does a general hyperplane section of $X$ have $\mathcal{W}$-rational singularities?
2. is a general cyclic cover, as in Theorem 3.21, $\mathcal{W}$-rational?

## 4. Proof of Theorem 1.1 and Corollary 1.2

### 4.1. Lemmas

**Lemma 4.1.** Let $f : X \to T$ be a surjective projective morphism of varieties such that both $T$ is not uniruled and the geometric generic fiber is integral. If $X$ is uniruled, then so is the geometric generic fiber $X_\pi$ of $f$.

**Proof.** First, note that by the definition [Kol96, Def IV.1.1], being uniruled is invariant under finite base-extension of geometrically integral varieties. Taking into account also [Kol96, Prop IV.1.3] one can even drop the word “finite”. In particular, we may assume that $k$ is uncountable.

Second, note that by shrinking $T$ we may assume that $f$ is flat. Then [Kol96, Thm 1.8.1] tells us that there are countably many subsets $\sqcup T_i$ such that $X_t$ is uniruled if and only if $t \not\in T_i$. Hence, it is enough to show that $T_i \neq T$ for all $i$, or equivalently, the very general closed fiber is uniruled.

As $T$ is not uniruled, according to [Kol96, IV.1.3.6] we are in the following situation: if $R_i$ is the closure of the image of the cycle map from the universal family over the space of degree $i$ rational curves on $T$, then

- $R_i \neq T$ for every $i$,
- there is no rational curve in $T$ through any $t \in T \setminus (\bigcup_i R_i)$.

Furthermore, according to [Kol96, IV.1.3.5], there is an open set $U \subseteq X$, such that there is a rational curve through each $x \in U(k)$ in $X$. Hence, for any $k$-point $x \in U \setminus (\bigcup_i f^{-1}R_i)$ there is a rational curve $C_x$ through $x$, but $f(C_x)$ cannot give a rational curve through $f(x)$.

Therefore, $C_x \subseteq X_{f(x)}$ must hold. This shows that for any $k$-point $t \in T \setminus (\bigcup_i R_i)$, there is a rational curve in $X_t$ through every closed point of $U \cap X_t$. Additionally, for general such $t$ we have $U \cap X_t \neq \emptyset$. Hence, we obtain that very general fibers of $f$ are uniruled.

**Lemma 4.2.** Let $f : X \to T$ be a surjective morphism of projective varieties with integral geometric generic fiber, and let $S : T$ be a finite flat morphism of varieties, then $X \times_T S$ is a projective variety (that is, it is integral).

**Proof.** By the geometric generic fiber assumption, the generic fiber of $X \times_T S \to S$ is integral [Har77, Exc II.3.15]. Hence, $X \times_T S$ is integral at its generic point, and then it is enough to see that $X \times_T S$ satisfies the $S_1$ property. Indeed, $S_1$ varieties have no embedded points by the definition of the $S_1$ property.

However, the fact that $X \times_T S$ is $S_1$ follows directly from the behavior of the depth along flat maps. In the special case of finite flat morphisms, which is $X \times_T S \to X$ in our case, the depth is simply the same for points lying over each other [Gro65, Prop6.3.1]. This concludes our proof.
4.2. The proof

Recall that a morphism of varieties is separable if the geometric generic fiber is reduced. Also, by the definition in Section 2.1, local complete intersection singularities are Gorenstein. According to point (1) of Proposition 2.1, if \( f : X \to T \) is a surjective local complete intersection morphism from a variety to a smooth variety, \( X \) has also local complete intersection singularities. Hence, in this case \( X \) is Gorenstein. Recall additionally that the general definitions of \( \omega_{X/T} \) and \( \omega_X \) are \( \omega_{X/T} := \mathcal{H}^{-\dim X/T}(f^*\mathcal{O}_T) \) and \( \omega_X := \mathcal{H}^{-\dim X}(g/\Spec k) \), where \( g : X \to \Spec k \) is the structure morphism. Therefore, whenever \( T \) is Gorenstein, and hence \( \omega_T \) is a line bundle, by [Nee96, Thm 5.4] we have

\[
\omega_{X/T} = \omega_X \otimes f^*\omega_T^{-1}.
\]

In the above special situation however we also know that both sides of (4.2.a) are line bundles, by the Gorenstein property. In particular, in this case, there is a well defined linear equivalence class \( K_{X/T} \) of Cartier divisors corresponding to \( \omega_{X/T} \), even if \( X \) is not normal, satisfying \( K_X = K_{X/T} + f^*K_T \). This is important to make sense of the statement of Theorem 4.3. It is also important to note that if \( S \to T \) is a flat morphism, then \( \omega_{X_S/S} \cong \tau^*\omega_{X/T} \), where \( X_S := X \times_T S \) and \( \tau : X_S \to X \) are the induced morphisms [Har66, Thm III.8.7.(5)]. Therefore, one has the following base-change isomorphism on the level of divisors:

\[
K_{X_S/S} \cong \tau^*K_{X/T}.
\]

**Theorem 4.3.** Let \( f : X \to T \) be a surjective, local complete intersection, separable, projective morphism to a smooth projective variety \( T \), such that the geometric generic fiber is connected and not uniruled. Then \( K_{X/T} \) is pseudo-effective.

**Proof.** Assume that \( K_{X/T} \) is not pseudo-effective. We will derive a contradiction.

Recall that a Cartier divisor is pseudo-effective if and only if its pullback under an arbitrary finite morphism is pseudo-effective. Hence, using Lemma 4.2 and (4.2.b), we may replace \( f \) by a pullback \( f_S \) via any finite flat morphism \( S \to T \) between smooth varieties. In particular, according to Theorem 3.21 we may assume that \( T \) is not uniruled.

Let \( F^n : T^n \to T \) be the \( n \)-times iterated Frobenius morphism (for all \( n \geq 0 \)), and set \( X^n := X \times_T T^n \). Then, by Lemma 4.1, \( X^n \) are not uniruled.

If \( K_{X/T} \) is not pseudo-effective, then there is a general element \( C \) of a moving family of curves on \( X \) with \( K_{X/T} \cdot C < 0 \) [Das17, Thm 1.4] [Full7, Rmk 2.1]. According to [Das17, Thm 1.4] we may even assume that \( C \) is irreducible.

Let \( C^n \) be the normalization of the reduced preimage of \( C \) in \( X^n \). We note that as \( \sigma^n : X^n \to X \) is inseparable, \( C^n \to C \) is a normalization followed by a few Frobenii. In particular, \( \sigma^n C^n = a_n C \) for some integer \( a_n > 0 \).

As \( C \) is general in a moving family, \( X^n \) is smooth along the general points of \( C^n \) and it has complete intersection singularities according to point (1) of Proposition 2.1. Hence [Kol96, Thm IV.5.14 & Rmk IV.5.15] applies to \( C^n \) and \( X^n \) as soon as we know that \( K_{X^n} \cdot C^n < 0 \). However, for \( n \gg 0 \) this is satisfied because of the following, where \( f^n : X^n \to T^n \) is the induced morphism:

\[
K_{X^n} \cdot C^n = \left( K_{X^n/T^n} + (f^n)^*K_{T^n} \right) \cdot C^n \equiv \frac{(\sigma^n)^* K_{X/T} + (f^n)^*(F^n)^*K_T}{p^n} \cdot C^n \quad (4.2.b) \text{and the fact that } (F^n)^*K_T \sim p^nK_T
\]

\[
\downarrow (f^n \circ f^n = f \circ \sigma^n) \quad \text{projection formula} \quad \uparrow \sigma^n C^n = a_n C \quad \text{for } n \gg 0, \text{ as } K_{X^n/T^n} \cdot C^n < 0
\]

So, according to [Kol96, Thm 5.14 & Rmk 5.15], for every \( n \gg 0 \), there is a rational curve through each point of \( C^n \). As \( C \) is general, there is a rational curve through a general point of \( X^n \). Hence \( X^n \) is uniruled. This is a contradiction, and hence our assumption that \( K_{X/T} \) is not pseudoeffective was false. \( \square \)
Proof of Theorem 1.1. This follows immediately from Theorem 4.3 using point (2) of Proposition 2.1. \qed

Proof of Corollary 1.2. As $K_{X/T}$ is $f$-big, we may write $K_{X/T} \sim_{\mathbb{Q}} A + E$, where $A$ is an $f$-ample and $E$ is an effective $\mathbb{Q}$-Cartier $\mathbb{Q}$-divisor on $X$. Similarly, we may write $K_T = H + G$, where $H$ is an ample and $G$ is an effective $\mathbb{Q}$-divisor on $T$. Hence, $K_X$ is big by the following computation, which concludes our proof:

$$K_X = f^*K_T + K_{X/T} = f^*G + f^*H + \varepsilon(A+E) + (1-\varepsilon)K_{X/T} \equiv \text{ample for } 0 < \varepsilon \ll 1, \text{ as } A \text{ is } f\text{-ample, and } H \text{ is ample} \quad \text{pseudo-effective by Theorem 1.1}$$

\qed
