ABSTRACT
In this paper, robust transceiver design based on minimum-mean-square-error (MMSE) criterion for dual-hop amplify-and-forward MIMO relay systems is investigated. The channel estimation errors are modeled as Gaussian random variables, and then the effects are incorporated into the robust transceiver based on the Bayesian framework. An iterative algorithm is proposed to jointly design the precoder at the source, the forward matrix at the relay and the equalizer at the destination, and the joint design problem can be efficiently solved by quadratic matrix programming (QMP).

1. INTRODUCTION
Recently, amplify-and-forward (AF) MIMO relay systems have gained more and more attention from both academic and industrial communities, due to its great potential to improve the wireless channel reliability [1], [2]. For practical applications, AF MIMO relay systems are to be adopted in future communication protocols, such as Winner Project, LTE and IMT-Advanced [2], to enhance the coverage of base stations.

For transceiver design, joint LMMSE transceiver with perfect channel state information (CSI) has been investigated in [3] and an iterative algorithm has been proposed. Unfortunately, in practice, CSI is generally obtained through estimation and perfect CSI is very difficult to achieve. Robust transceiver design, which could mitigate such performance degradation by taking the channel estimation errors into account, is therefore of great importance and highly desirable for practical applications.

In this paper, we consider robust linear transceiver design for AF MIMO relay systems under imperfect CSI at both the relay and destination. The precoder at the source, the forward matrix at the relay and the equalizer at the destination are jointly designed based on minimum-mean-square-error (MMSE) criterion. With the channel estimation errors being modeled as Gaussian random variables, robustness is incorporated into the optimization objective function by taking expectation with respect to the channel estimation errors. The joint design problem can efficiently solved by quadratic matrix programming (QMP) [7]. Simulation results show that the proposed robust algorithm performs better than the transceiver design without taking channel estimation errors into account.

The following notations are used throughout this paper. Boldface lowercase letters denote vectors, while boldface uppercase letters denote matrices. The notations $Z^T$, $Z^H$ and $Z^*$ denote the transpose, Hermitian and conjugate of the matrix $Z$, respectively, and $\text{Tr}(Z)$ is the trace of the matrix $Z$. The symbol $I_M$ denotes the $M \times M$ identity matrix, while $0_{M \times N}$ denotes the $M \times N$ all zero matrix. The symbol $\mathbb{E}\{\cdot\}$ represents the expectation operation. The operation $\text{vec}(Z)$ stacks the columns of the matrix $Z$ into a single vector. The symbol $\otimes$ denotes the Kronecker product.

2. SYSTEM MODEL
In this paper, a dual-hop amplify-and-forward (AF) cooperative communication system is considered. In the considered system, there is one source with $N_S$ antennas, one relay with $M_R$ receive antennas and $N_R$ transmit antennas, and one destination with $M_D$ antennas, as shown in Fig. 1. At the first hop, the source transmits data to the relay. The received signal, $x$, at the relay is
\begin{equation}
x = H_{sr}Ps + n_1,
\end{equation}
where $s$ is the $N \times 1$ data vector transmitted by the source with the covariance matrix $R_s = \mathbb{E}\{ss^H\} = I_N$, $P$ is the precoder

![Fig. 1. Amplify-and-forward MIMO relay diagram.](image-url)
matrix with a transmit power constraint, \( \text{Tr}(PP^H) \leq P_s \), with \( P_s \) is the maximum transmit power at the source. The matrix \( H_{sr} \) is the MIMO channel matrix between the source and the relay. Symbol \( n_1 \) is the additive Gaussian noise with covariance matrix \( R_{n_1} \).

At the relay, the received signal \( x \) is multiplied by a forward matrix \( F \), under a power constraint \( \text{Tr}(RF_sF^H) \leq P_r \), where \( R_x = E\{xx^H\} \) and \( P_r \) is the maximum transmit power. Then the resultant signal is transmitted to the destination. The received signal \( y \) at the destination can be written as

\[
y = H_{rd}F_{rd}Ps + H_{rd}Fn_1 + n_2,
\]

where \( H_{rd} \) is the MIMO channel matrix between the relay and the destination, and \( n_2 \) is the additive Gaussian noise vector at the second hop with covariance matrix \( R_{n_2} \).

In order to guarantee the transmitted data \( s \) can be recovered at the destination, it is assumed that \( N_S, M_R, N_R, \text{ and } M_D \) are greater than or equal to \( N \).

It is assumed that both the relay and destination have the estimated channel state information (CSI). When channel estimation errors are considered, we have \( H_{sr} = \bar{H}_{sr} + \Delta H_{sr} \) and \( H_{rd} = \bar{H}_{rd} + \Delta H_{rd} \), where \( \bar{H}_{sr} \) and \( \bar{H}_{rd} \) are the estimated CSI, while \( \Delta H_{sr} \) and \( \Delta H_{rd} \) are the corresponding channel estimation errors whose elements are zero mean Gaussian random variables. In general, the \( M_R \times N_S \) matrix \( \Delta H_{sr} \) can be written as \( \Delta H_{sr} = \Sigma_{sr}^T H_{sr} \Psi_{sr} \), where the elements of the \( M_R \times N_S \) matrix \( H_{sr} \) are independent and identically distributed (i.i.d.) Gaussian random variables with zero mean and unit variance. The \( M_R \times M_R \) matrix \( \Sigma_{sr} \) and \( N_S \times N_S \) matrix \( \Psi_{sr}^T \) are the row and column covariance matrices of \( H_{sr} \), respectively. The matrix \( \Delta H_{sr} \) is said to have a matrix-variate complex Gaussian distribution, which can be written as \( \Delta H_{sr} \sim C N_{M_R,N_S} \left( 0, \Sigma_{sr} \otimes \Psi_{sr}^T \right) \) \[6\]. Similarly, for the estimation error in the second hop, we have \( \Delta H_{rd} \sim C N_{M_D,N_R} \left( 0, \Sigma_{rd} \otimes \Psi_{rd}^T \right) \), where the \( M_D \times M_D \) matrix \( \Sigma_{rd} \) and \( N_R \times N_R \) matrix \( \Psi_{rd}^T \) are the row and column covariance matrices of \( \Delta H_{rd} \), respectively. It is assumed that \( \Delta H_{sr} \) and \( \Delta H_{rd} \) are estimated independently, so the channel estimation errors, \( \Delta H_{sr} \) and \( \Delta H_{rd} \), are independent.

3. PROBLEM FORMULATION

At the destination, a linear equalizer \( G \) is adopted to detect the transmitted data \( s \). The problem is how to design the linear precoder matrix \( P \) at the source, the linear forward matrix \( F \) at the relay and the linear equalizer \( G \) at the destination to minimize the mean square errors (MSE) of the received data at the destination:

\[
\text{MSE}(G, F, P) = E\{\| (G_{rd}F_{rd}P - I_N)s + G_{rd}Fn_1 + G_{rd}n_2 \|^2 \}
\]

where the expectation is taken with respect to \( s, \Delta H_{sr}, \Delta H_{rd}, n_1 \) and \( n_2 \). Since \( s, n_1 \) and \( n_2 \) are independent, the MSE expression (3) can be written as

\[
\text{MSE}(G, F, P) = E_{\Delta H_{sr}, \Delta H_{rd}} \{ \text{Tr}((G_{rd}F_{rd}P)(G_{rd}F_{rd}P)^H) \}
\]

where \( E_{\Delta H_{sr}, \Delta H_{rd}} \) is the expectation with respect to \( \Delta H_{sr} \) and \( \Delta H_{rd} \), the first term of MSE is

\[
\text{MSE}(G, F, P) = Tr\left( (G_{rd}F_{rd}P)(G_{rd}F_{rd}P)^H \right).
\]

For the inner expectation, due to the fact that the distribution of \( \Delta H_{sr} \) is matrix-variate complex Gaussian with zero mean, the following equation holds \[6\]

\[
\text{MSE}(G, F, P) = \text{Tr}(PP^H) \text{MSE}(\Psi_{sr}) + \Delta H_{sr} \Sigma_{sr} \Delta H_{sr}^H H_{sr}^H \Delta H_{sr}^H \Psi_{sr} \triangleq \Pi_p.
\]

Applying (6) and the corresponding result for \( \Delta H_{rd} \) to (5), the first term of MSE in (4) becomes

\[
\text{MSE}(G, F, P) = \text{Tr}(PP^H) \text{MSE}(\Psi_{sr}) + \Delta H_{sr} \Sigma_{sr} \Delta H_{sr}^H H_{sr}^H \Delta H_{sr}^H \Psi_{sr} \triangleq \Pi_p.
\]

With similar calculations applied to the second term of MSE, the total MSE in (4) can be shown to be

\[
\text{MSE}(G, F, P) = \text{Tr}(PP^H) \text{MSE}(\Psi_{sr}) + \Delta H_{sr} \Sigma_{sr} \Delta H_{sr}^H H_{sr}^H \Delta H_{sr}^H \Psi_{sr} \triangleq \Pi_p.
\]

where \( R_x = \Pi_p + R_{n_2} \) and \( K = \text{Tr}(FR_xF^HP_{rd}^H)R_{rd} + R_{n_2} \). Notice that the matrix \( R_x \) is the autocorrelation matrix of the receive signal \( x \) at the relay. Finally, the joint transceiver design can be formulated as the following optimization problem

\[
\begin{align*}
\min_{G,F,P} & \quad \text{MSE}(G, F, P) \\
\text{s.t.} & \quad \text{Tr}(PP^H) \leq P_s, \quad \text{Tr}(FR_xF^H) \leq P_r.
\end{align*}
\]

4. THE PROPOSED SOLUTION

In this section, we derive an iterative algorithm to solve for \( P, F \) and \( G \). In the following, it is shown that given any two variables of \( P, F \) and \( G \), the remaining one can be efficiently solved. Therefore, the proposed algorithm computes \( P, F \) and \( G \) iteratively, starting with initial values.

Design of \( G \) : When the precoder \( P \) at the source and the forward matrix \( F \) at the relay are fixed, the optimization problem (9) is an unconstrained convex optimization
The optimal equalizer $G$ must satisfy
\[ \frac{\partial \text{MSE}(G, F, P)}{\partial G^*} = 0 \] which gives
\[ G = (\bar{H}_{rd}F \bar{H}_{sr}P)(\bar{H}_{rd}FR_{x}F^H \bar{H}_{rd}^* + K)^{-1}. \] \hspace{1cm} (10)

**Design of $F$**: When $P$ and $G$ are fixed, the optimization problem (9) becomes
\[
\min_{F} \text{MSE}(G, F, P) \quad \text{s.t.} \quad \text{Tr}(FR_x F^H) \leq P_r. \hspace{1cm} (11)
\]

Generally speaking, the optimization problem (11) is a quadratic matrix programming (QMP) problem with the variable $FR_x^{1/2}$ and only one constraint. We can formulate it into a semi-definite programming (SDP) problem to solve for $F$. However, because there is only one constraint, in the following, we introduce another algorithm to compute $F$ based on Karush-Kuhn-Tucker (KKT) conditions, and has a much lower complexity. The corresponding KKT conditions of (11) are given as follows
\[
F = (\bar{H}_{rd}^H G^* \bar{H}_{rd} + \Psi_{rd} \text{Tr}(G \Sigma_{rd} G^H) + \lambda \Omega_{N_r})^{-1} \times \bar{H}_{rd}^H G^* \bar{H}_{rd} F^H R_x^{-1}. \hspace{1cm} (12a)
\]
\[
\lambda(\text{Tr}(FR_x F^H) - P_r) = 0 \hspace{1cm} (12b)
\]
\[
\lambda \geq 0, \quad \text{Tr}(FR_x F^H) \leq P_r. \hspace{1cm} (12c)
\]

Obviously from (12a), in order to compute the optimal $F$, the Lagrangian multiplier $\lambda$ should be calculated first. However, there is no closed-form solution of $\lambda$ simultaneously satisfying (12b) and (12c). Below we propose a low complexity method to solve (12b) and (12c). First, notice that in order to have (12b) satisfied, either $\lambda = 0$ or $\text{Tr}(FR_x F^H) = P_r$ must hold. If $\lambda = 0$ also makes (12c) satisfied, $\lambda = 0$ is a solution to (12b) and (12c). Since given $G$ and $P$, the optimization problem (11) is a convex quadratic programming problem of $F$, which has only one solution for $F$, $\lambda = 0$ is the only solution to (12b) and (12c) in this case.

On the other hand, if $\lambda = 0$ does not make (12c) satisfied, we have to solve $\text{Tr}(FR_x F^H) = P_r$. It can be proved that when $G$ and $P$ are fixed, the function $f(\lambda) = \text{Tr}(FR_x F^H)$ is a decreasing function of $\lambda$ which satisfies
\[
0 \leq \lambda \leq \sqrt{\text{Tr}(\bar{H}_{rd}^H G^* \bar{H}_{rd} F^H R_x^{-1} \bar{H}_{rd}^H P \bar{H}_{rd}^H) / P_r}. \hspace{1cm} (13)
\]

Due to space limitation, the proof is not presented here. Based on this result, $\lambda$ can be efficiently computed by a one-dimension search, such as bisection search or golden search. Since $\text{Tr}(FR_x F^H) = P_r$ is a stronger condition than $\text{Tr}(FR_x F^H) \leq P_r$, (12c) is satisfied automatically in this case. In summary, we take $\lambda = 0$, if $f(0) \leq P_r$, and solve $f(\lambda) = P_r$ otherwise.

**Design of $P$**: When $F$ and $G$ are fixed, after a lengthy and tedious derivation, it can be shown that the optimization problem (9) is equivalent to the following QMP problem [4]
\[
\min_{P} \text{Tr}(P^H A_o P) + 2 \text{Re} \text{Tr}(B_p^H P)) + c_0 \\ \text{s.t.} \quad \text{Tr}(P^H A_1 P) + 2 \text{Re} \text{Tr}(B_{1p}^H P) + c_1 \leq 0 \\ \text{Tr}(P^H A_2 P) + 2 \text{Re} \text{Tr}(B_{2p}^H P) + c_2 \leq 0. \hspace{1cm} (14)
\]

where the parameters are defined as follows
\[ A_0 = \Psi_{sr} \text{Tr}(F \Sigma_{sr} F^H M) + \bar{H}_{rd}^H F^H M P \bar{H}_{sr}, \]
\[ M \triangleq \Psi_{sr} \text{Tr}(G \Sigma_{sr} G^H) + \bar{H}_{rd}^H G^H \bar{H}_{rd}, \]
\[ B_0 = -G \bar{H}_{rd} F \bar{H}_{sr}, \]
\[ B_1 = -G \bar{H}_{rd} F \bar{H}_{sr}, \]
\[ B_2 = 0. \]

It is known that QMP problems can be transformed into semi-definite programming (SDP) problems which can be efficiently solved by interior point polynomial algorithms [4]. Based on the properties of Kronecker product and the following definition
\[
\Omega_i \triangleq \begin{bmatrix}
I_N \otimes A_i & \text{vec}(B_i) \\
\text{vec}^H(B_i) & c_i
\end{bmatrix}, \quad i = 0, 1, 2, \hspace{1cm} (16)
\]

the optimization problem (14) is equivalent to
\[
\min_{X} \text{Tr}(\Omega_0 X) \\ \text{s.t.} \quad \text{Tr}(\Omega_1 X) \leq 0, \quad \text{Tr}(\Omega_2 X) \leq 0 \\ X = [\text{vec}^T(P)]^T [\text{vec}^H(P)] \hspace{1cm} (17)
\]

If the constraint $\text{Rank}(X) = 1$ is relaxed (it is a well-known semi-definite relaxation (SDR) [7], [8]), we have the following SDP relaxation problem
\[
\min_{Z} \text{Tr}(\Omega_0 Z) \\ \text{s.t.} \quad \text{Tr}(\Omega_1 Z) \leq 0, \quad \text{Tr}(\Omega_2 Z) \leq 0 \\ [Z]_{N_r+1,NN^2+1} = 1, \quad Z \succeq 0, \hspace{1cm} (18)
\]

where $Z$ is a Hermitian matrix. Because the QMP problem (14) is a convex quadratic programming problem, the relaxation gap of SDR is zero. In other words, the optimization programs (17) and (18) have the same optimal solution [4], [9].

**Summary and Convergence Analysis**: Initialize $P$ and $F$ which satisfy $\text{Tr}(P^H P) = P_r$ and $\text{Tr}(FR_x F^H) = P_r$. For simplicity, we can take $P \propto I$ and $F \propto I$. Then the proposed iterative algorithm proceeds between (10), (12a) and (18), until $\|\text{MSE}_i - \text{MSE}_{i-1}\| \leq t$ where $\text{MSE}_i$ is the MSE (8) in the $i$th iteration, and $t$ is a threshold. Since for any two of the $P$, $F$ and $G$ fixed, the optimization problem (9) is a convex problem for the remaining variable, the proposed algorithm is an alternative projection algorithm which is guaranteed to converge.

5. **Simulation Results and Discussions**

In this section, we will investigate the performance of the proposed algorithm and for the purpose of comparison, the algorithm based on the estimated channel only (without taking
the channel errors into account) [3] is also simulated. In order to solve the SDP problem, the matlab toolbox CVX is used [10]. In the following, we consider an AF MIMO relay system where the source, relay and destination are equipped with same number of antennas, i.e., $N_S = M_R = N_R = M_D = 4$. The estimated channels $\mathbf{H}_{sr}$ and $\mathbf{H}_{rd}$ are randomly generated as

$$
\mathbf{R}_{sr} = \begin{bmatrix}
1.02 + .82i & -0.1 - 0.61i & 12 - 26i & .92 + 64i \\
.08 + 90i & .70 - 1.22i & .06 + 19i & .46 + 62i \\
1.43 - 1.23i & .72 - 70i & -.23 + 84i & .03 + 25i \\
.43 - 71i & 1.56 - 23i & 29 + 1.30i & -.63 + 73i
\end{bmatrix}
$$

$$
\mathbf{R}_{rd} = \begin{bmatrix}
1.01 - 1.22i & .36 - 29i & .08 + 50i & -.01 + 37i \\
-.89 - 1.23i & 1.05 - 06i & .32 - 24i & .45 + 73i \\
-50 + 23i & -45 - 14i & -.55 + 42i & 1.01 + 23i \\
-1.00 + 38i & -54 + 31i & -.00 + 62i & 82 + 1.32i
\end{bmatrix}
$$

Here the channel estimation algorithm in [5] is adopted, the correlation matrices of channel estimation errors are in the form [5].

$$
\Psi_{sr} = \mathbf{R}_{T,sr} \Sigma_{sr} = \sigma_e^2 (\mathbf{I} + 2\mathbf{R}_{sr})^{-1},
$$

$$
\Psi_{rd} = \mathbf{R}_{T,rd} \Sigma_{rd} = \sigma_e^2 (\mathbf{I} + 2\mathbf{R}_{rd})^{-1},
$$

where $\sigma_e^2$ denotes the estimation error variance [5]. The matrices $\mathbf{R}_{T,sr}$ and $\mathbf{R}_{R,rd}$ are the transmit and receive correlation matrices in the first hop, respectively, and similar definitions apply to $\mathbf{R}_{T,rd}$ and $\mathbf{R}_{R,rd}$ for the second hop. The widely used exponential model [5] is chosen for the transmit and receive channel correlation matrices, i.e., $(\mathbf{R}_{T,sr})_{i,j} = (\mathbf{R}_{T,rd})_{i,j} = \alpha^{\left|i-j\right|}, (\mathbf{R}_{R,rd})_{i,j} = (\mathbf{R}_{R,rd})_{i,j} = \beta^{\left|i-j\right|}$

where $\alpha$ and $\beta$ are the correlation coefficients. We define the signal-to-noise ratio for the source-relay link (SNR$_{sr}$) as $E_s/N_1 = P_s/\text{Tr}(\mathbf{R}_{sr})$, and is fixed as $E_s/N_1 = 30\text{dB}$. At the source, four independent data streams are transmitted. For each data stream, 10$^3$ independent QPSK symbols are transmitted. The SNR for the relay-destination link (SNR$_{rd}$) is defined as $E_r/N_2 = P_r/\text{Tr}(\mathbf{R}_{rd})$. Each point in the following figure is an average of 1000 independent realization of estimation errors.

Fig. 2 shows the bit-error-rate (BER) performance of the proposed algorithm and the algorithm based on estimated channels only with different $\sigma_e^2$, when $\alpha = 0.5$ and $\beta = 0.4$. It can be seen that when the channel estimation errors decreases, the performances of both algorithms improve and they coincide at $\sigma_e^2 = 0$. Furthermore, the performance of the proposed algorithm is always better than that of the algorithm based on estimated channels only.

6. CONCLUSIONS

In this paper, based on the Bayesian framework, robust linear transceiver design for dual-hop AF MIMO relay systems has been considered. The precoder matrix at the source, the linear forward matrix at the relay and the linear equalizer at the destination have been jointly designed based on minimum-mean-square-error (MMSE) criterion. An iterative algorithm is proposed, and at each step, the design problem can be formulated as a QMP problem which can be efficiently solved.

Simulation results showed that the performance of the proposed robust algorithm is always better than that of the algorithm based on estimated channels only.
