Recently, in the Luttinger liquid phase of the one-dimensional generalized antiferromagnetic Kitaev spin-$1/2$ model, it has been found that the abelian bosonization formulas of the local spin operators only respect the exact discrete nonsymmorphic symmetry group of the model, not the emergent U(1) symmetry. In this work, we perform a renormalization group (RG) study to provide explanations for the origin of the U(1) breaking terms in the bosonization formulas. We find that the lack of U(1) symmetry originates from the wavefunction renormalization effects in the spin operators along the RG flow induced by the U(1) breaking interactions in the microscopic Hamiltonian. In addition, the RG analysis can give predictions to the signs and order of magnitudes of the coefficients in the bosonization formulas. Our work is helpful to understand the rich nonsymmorphic physics in one-dimensional Kitaev spin models.

I. INTRODUCTION

Kitaev materials have attracted intense research attentions in the past decade,[10,22] since they not only provide potential experimental platforms for realizing the Kitaev spin-$1/2$ model on the honeycomb lattice – a prototypical strongly correlated model for topological quantum computations,[23,26] but also are representatives of frustrated magnetic systems, having close relations to the fields of strongly correlated quantum magnets,[27,28] and quantum spin liquids.[29–34] Theoretical and experimental studies have established the fact that Kitaev materials can be described by generalized Kitaev spin models[35–48] which – in addition to Kitaev interaction – contain other types of couplings including the Heisenberg interaction, the off-diagonal $\Gamma$ and $\Gamma'$ terms, and beyond nearest neighbor interactions. One of the central themes in the field of Kitaev materials is to understand the effects of such additional interactions which are inevitable in real materials.

Recently, there has been increasing interests in studying one-dimensional (1D) Kitaev spin models,[43,45] which are constructed by selecting one row out of the honeycomb lattice. These 1D Kitaev spin models have discrete nonsymmorphic symmetry group structures,[40,41] leading to rich physics including emergent conformal symmetries, extended Luttinger liquid phases in the phase diagram, nonvanishing string order parameters, and magnetically ordered phases with exotic symmetry breaking patterns such as $O_h \rightarrow D_{2d}^{[10,11]}$, $O_h \rightarrow D_{3d}^{[12,13]}$, $O_h \rightarrow D_{4d}^{[14]}$, and $D_{3d} \rightarrow \mathbb{Z}_2^{[15]}$, where $O_h$ is the full octahedral group, $D_n$ is the dihedral group of order $2n$, and $D_{3d} \cong D_3 \times \mathbb{Z}_2$. The motivation of such 1D studies is to provide hints and guidance for the 2D physics. Indeed, it has been demonstrated in Ref. [44] that the zigzag phase in 2D Kitaev-Heisenberg-Gamma model can be obtained by weakly coupling an infinite number of 1D chains, thereby providing a controllable approach to the 2D zigzag order. In addition, 1D studies also have their independent merits, since there have been proposals on realizing 1D generalized Kitaev spin models in real materials.[43]

As shown in Ref. [40], the system has an emergent U(1) symmetry at low energies in the gapless Luttinger liquid phase in the generalized Kitaev spin-$1/2$ chain with an antiferromagnetic (AFM) Kitaev coupling. At first sight, it seems that the discrete nature of the nonsymmorphic symmetry group is lost in the long wavelength limit. However, as discussed in detail in Ref. [44], the discreteness of the nonsymmorphic symmetry group still has notable influence on the low energy properties, reflected by the constraints on the abelian bosonization formulas for the spin operators. The abelian bosonization formulas build the connections between the lattice spin operators on one side and the low energy field theory degrees of freedom on the other side, and the two sides have to be covariant under symmetry transformations.

One typical type of the nonsymmorphic symmetry operations is the screw operation, where a spatial translation followed by a spin rotation is a symmetry of the system, whereas neither the translation nor the spin rotation alone leaves the system invariant. Unlike the on-site spin rotational symmetry in a translationally invariant system, a screw symmetry relates the spin operators on different sites. Hence it is expected that the constraint imposed by a screw symmetry is much looser than the constraints imposed by translation plus global spin rotation.

Indeed, it was found in Ref. [44] that the bosonization formulas for the spin-$1/2$ Kitaev-Heisenberg-Gamma chain contain a large number (equal to ten) of nonuniversal bosonization coefficients, which are only compatible with the exact nonsymmorphic symmetry group, not respecting the emergent U(1) symmetry. The ten bosonization coefficients are determined by density matrix renormalization group (DMRG) numerical simulations to a high degree of accuracy[40]. However, although a symmetry analysis is able to determine the constraints
on the relations among the bosonization coefficients, it
cannot give any prediction on the magnitudes or signs of
the coefficients, neither can it provide explanations for
the mechanism of how these coefficients arise.

In this work, in view of the aforementioned incapability
of the symmetry analysis, we perform a renormalization
group (RG) study in the Luttinger liquid phase of the
Kitaev-Heisenberg-Gamma spin-1/2 chain in the AFM
Kitaev region. The basic idea is that the U(1) breaking
terms in the microscopic Hamiltonian renormalize the
spin operators along the RG flow, and the nonsymmor-
phic bosonization coefficients are reminiscences of such
renormalization effects in the low energy physics. Our
RG study is able to explain the origin of the U(1) break-
ing bosonization coefficients. In addition, it can also give
predictions on the signs and order of magnitudes of the
bosonization coefficients. We note that as revealed by
this RG study, the U(1) breaking effects in the bosoniza-
tion coefficients are indeed, it correctly captures the qualitative features of
the coefficients, neither can it provide explanations for
the mechanisms of how these coefficients arise.

The rest of the paper is organized as follows. In Sec. II,we introduce the model Hamiltonian, discuss the phase
diagram of the model, and give a review on the nonsymnor-
phic bosonization formulas in the Luttinger liquid
phase under interest. In Sec. III, the general framework
of the RG treatment in this work is formulated. Sec. IV
derives and solves the RG flow equations for the scaling
fields which are coupled to the spin operators. In Sec. V,
the bosonization coefficients are derived by solving the
flow equations. Finally in Sec. VI, we briefly summarize
the main results of the paper.

II. NONSYMMORPHIC BOSONIZATION
FORMULAS

A. Model Hamiltonian

We consider a spin-1/2 Kitaev-Heisenberg-Gamma
chain in zero magnetic field defined as

\[ H = \sum_{<ij> \in \gamma \text{ bond}} [K S_i^\alpha S_j^\alpha + J S_i^\beta \cdot S_j^\beta + \Gamma (S_i^\gamma S_j^\gamma + S_i^\delta S_j^\delta)], \tag{1} \]

in which \(i, j\) are two sites of nearest neighbors; \(\gamma = x, y\)
is the spin direction associated with the \(\gamma\) bond shown in
Fig. 2(a); \(\alpha \neq \beta\) are the two remaining spin directions
other than \(\gamma\); \(K, J\) and \(\Gamma\) are the Kitaev, Heisenberg and
Gamma couplings, respectively. The coupling constants
\(K, \Gamma\) can be parametrized as \(K = \cos(\psi)\), \(\Gamma = \sin(\psi)\),
in which \(\psi \in [0, \pi]\). The phase diagram of the model in
terms of \(J, \psi\) is shown in Fig. 2.

![FIG. 2: Phase diagram of the spin-1/2 Kitaev-Heisenberg-
Gamma chain in the region \(K > 0, J < 0\), in which the ver-
tical axis is \(J\) and the horizontal axis is \(\psi\) where \(K = \cos(\psi)\)
and \(\Gamma = \sin(\psi)\). In the figure, “LL” and “FM” denote the Lut-
tinger liquid and FM phases, respectively. A useful unitary trans-
formation is called four-sublattice rotation \(U_4\), which is defined as

\[
\begin{align*}
\text{Sublattice 1:} & (x, y, z) \rightarrow (-x', y', -z'), \\
\text{Sublattice 2:} & (x, y, z) \rightarrow (-x', -y', z'), \\
\text{Sublattice 3:} & (x, y, z) \rightarrow (x', -y', -z'), \\
\text{Sublattice 4:} & (x, y, z) \rightarrow (x', y', z'),
\end{align*}
\tag{2}
\]

in which “Sublattice \(i\)” \((1 \leq i \leq 4)\) represents all the
sites \(i + 4n \ (n \in \mathbb{Z})\) in the chain, and we have dropped the
spin symbol \(S\) for simplicity (i.e., \(\alpha\) is understood as
\(S^\alpha\) where \(\alpha = x, y, z\)). The Hamiltonian \(H' = U_4 H U_4^{-1}\)
in the four-sublattice rotated frame acquires the form

\[
H' = \sum_{<ij> \in \gamma \text{ bond}} [(K + 2J) S_i^\gamma S_j^\gamma - J S_i^\beta \cdot S_j^\beta + \epsilon(\gamma) \Gamma (S_i^\alpha S_j^\alpha + S_i^\delta S_j^\delta)],
\tag{3}
\]

in which the bonds \(\gamma = x, y, \tilde{x}, \tilde{y}\) has a four-site peri-
docity as shown in Fig. 1(b); the function \(\epsilon(\gamma)\) is defined as
\(\epsilon(x) = \epsilon(y) = -\epsilon(x) = -\epsilon(y) = 1; S_i^\gamma = S_i^\gamma\); and
\(U_4 S_i^\gamma U_4^{-1}\) is denoted as \(S_i^\gamma\) for short. Notice that
\(U_4\) reveals a hidden SU(2) symmetric point located at
\(K + 2J = 0, \Gamma = 0\). At this point, \(H'\) is exactly the SU(2)
symmetric AFM Heisenberg model. Explicit forms of \( H \) and \( H' \) are included in Appendix A.

From here on, we will stick to the four-sublattice rotated frame unless otherwise stated.

### B. Phase diagram in the antiferromagnetic Kitaev region

The phase diagram in the region \( K > 0, J < 0 \) is shown in Fig. 2. Since a global spin rotation around \( z \)-axis by \( \pi \) changes the sign of \( \Gamma \) but leaves \( K \) and \( J \) invariant, it is enough to consider the \( \Gamma > 0 \) region.

As can be seen from Fig. 2, there are two phases close to the \( \Gamma = 0 \) line (i.e., the vertical axis), including a Luttinger liquid phase (denoted as LL in Fig. 2), and a ferromagnetically ordered phase (denoted as FM). It has been shown in Ref. 44 that in the sense of low energy field theory, the phase boundary between the LL and FM is essentially a phase transition between planar and axial spin-1/2 XXZ chains. Hence, the low energy physics of this phase boundary is described by the SU(2)1 Wess-Zumino-Witten (WZW) model.

In this paper, we will focus on the Luttinger liquid phase in Fig. 2.

### C. Nonsymmorphic abelian bosonization formulas

In this subsection, we briefly review the nonsymmorphic bosonization formulas in the Luttinger liquid phase in Fig. 2 which are proposed in Ref. 44 based on a symmetry analysis.

The system in the four-sublattice rotated frame is invariant under the following symmetry operations \( 40,44 \):

\[
T : (S^x_i, S^y_i, S^z_i) \rightarrow (-S^x_i, -S^y_i, S^z_i) \\
R(\hat{y}, \pi)I : (S^x_i, S^y_i, S^z_i) \rightarrow (-S^z_{i-1}, S^y_{i-1}, -S^x_{i-1}) \\
R(\hat{z}, -\pi)T_a : (S^x_i, S^y_i, S^z_i) \rightarrow (-S^y_{i+1}, S^x_{i+1}, S^z_{i+1}), \tag{4}
\]

in which \( T \) is time reversal; \( I \) is the spatial inversion with inversion center located at the middle of the bond connecting sites 2 and 3; \( T_{na} \) is the spatial translation by \( n \) sites; and \( R(\hat{n}, \theta) \) represents a global spin rotation around \( \hat{n} \)-axis by an angle \( \theta \). It has been proved in Refs. \( 40,44 \) that the symmetry group \( G = \langle T, R(\hat{y}, \pi)I, R(\hat{z}, -\pi)T_a \rangle \) is nonsymmorphic and satisfies \( G/T_{4\pi} \cong \mathbb{Z}_2 \times \mathbb{Z}_4 \), in which \( \langle \ldots \rangle \) represents the group generated by the elements within the bracket; and \( T_{4d} \equiv \mathbb{Z}_2 \times \mathbb{Z}_4 \).

In the Luttinger liquid phase, the low energy theory is described by the Luttinger liquid Hamiltonian

\[
H_{LL} = \frac{v}{2} \int dx [\kappa^{-1}(\nabla \varphi)^2 + \kappa(\nabla \theta)^2], \tag{5}
\]

in which \( v \) is the velocity; \( \kappa \) is the Luttinger parameter; and the fields \( \theta, \varphi \) satisfy \( [\varphi(x), \theta(x')] = \frac{i}{2} \text{sgn}(x' - x) \).

For later convenience, it is useful to define the following fields,

\[
J^\pm = \frac{2}{a} \cos(\sqrt{\pi} \varphi) e^{\pm i \sqrt{\pi} \theta}, \quad J^z = -\sqrt{2} \pi \nabla \varphi, \\
N^\pm = \frac{\sqrt{2}}{a} e^{\pm i \sqrt{\pi} \theta}, \quad N^z = \frac{\sqrt{2}}{a} \sin(\sqrt{4\pi} \varphi), \tag{6}
\]

where \( J^\pm = J^x \pm J^y \) and \( N^\pm = N^x \pm iN^y \). Since \( \int dx J^a(x) \) is the generator for the global spin rotation around \( z \)-axis, \( J^a \) and \( N^a \) transform under \( R(\hat{z}, \beta) \) as \( \lambda^a \rightarrow \lambda^a e^{i\beta/2} \) and \( \lambda^a \rightarrow \lambda^a \), where \( A = J, N \). Clearly, the low energy field theory has an emergent U(1) symmetry corresponding to rotations around \( z \)-axis, even though the microscopic Hamiltonian only has a discrete nonsymmorphic symmetry group.

On the other hand, the discrete and nonsymmorphic nature of the symmetry group still has significant effects on the low energy properties of the system. We note that when the microscopic Hamiltonian is U(1) invariant (for example, the planar XXZ model), the bosonization formulas of the spin operators are given by \( S^a = \lambda J^a + \mu(\pm 1)N^a \), in which \( \lambda, \mu \) are constants. However, these relations cease to apply in the Kitaev-Heisenberg-Gamma chain. In Ref. 44 the following nonsymmorphic bosonization formulas are proposed

\[
S_{j+4n}^a = \sum_\beta [D^a_j J^\beta(x) + (-)^j C^a j \beta N^\beta(x)], \tag{7}
\]

in which: \( n \) is the index for the unit cell; \( j \ (1 \leq j \leq 4) \) represents the site within the four-site unit cell; \( x = j + 4n \) is the spatial coordinate in the continuum limit; and \( \alpha, \beta = x, y, z \).

Two comments are in order. First, Eq. (7) was obtained in Ref. 44 by covariance of the two sides under symmetry transformations. Notice that for nonsymmetry transformations, the two sides in Eq. (7) are not covariant, since the transformed \( J^a \) and \( N^a \) operators are driven out of the low energy subspace of the Hilbert space in such situations. Second, Eq. (7) equally applies to nonabelian bosonization formulas in the nonsymmetric case, except that the \( J^a \) and \( N^a \) operators should be replaced by the WZW current operators and primary fields, respectively. As shown in Fig. 2 the line separating LL and FM phases has an emergent SU(2)1 conformal symmetry at low energies (see Ref. 44 for details). Therefore, a nonabelian bosonization version of Eq. (7) should be used along this phase transition line.

Defining \( 3 \times 3 \) matrices \( D_j \) and \( C_j \) whose matrix elements at position \( (\alpha, \beta) \) are \( D_{j}^{\alpha \beta} \) and \( C_{j}^{\alpha \beta} \), the coefficients in Eq. (7) can be compactly expressed as

\[
D_1 = \begin{pmatrix} a_D & b_D & c_D \\ b_D & a_D & -c_D \\ h_D & -i_D & i_D \end{pmatrix},
\]

\[
D_j = (M_z)^{-1} D_1 (M_z)^{-j}, \tag{8}
\]
and
\[ C_1 = \begin{pmatrix} a_C & b_C & c_C \\ b_C & a_C & -c_C \\ h_C & -h_C & i_C \end{pmatrix}, \]
\[ C_j = (M_z)^{-1} C_1 (M_z)^{1-j}, \tag{9} \]
where \( j = 2, 3, 4, \) and
\[ M_z = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{10} \]

It can be seen that there are ten non-universal coefficients in Eq. (7), which spoil the emergent U(1) symmetry and only respect the exact nonsymmorphic symmetries of the system. Explicit expressions of the nonsymmorphic bosonization formulas are included in Appendix B.

On the other hand, although the symmetry analysis is able to determine the form of the bosonization formulas, it has no predictive power on the order of magnitudes nor the signs of the ten bosonization coefficients \( a_{1,A}, b_{1,A}, c_{1,A}, h_{1,A}, i_{1,A} (\Lambda = C, D). \) In addition, the symmetry analysis gives no explaination to the origin of the bosonization coefficients, i.e., there is no information on how they arise microscopically. In view of these issues, it is the purpose of this work to derive the ten bosonization coefficients using an RG approach.

### III. SETUP FOR RG FLOWS

In this section, we set up the method for deriving the RG flow equations which can provide explanations for the microscopic origin of the nonsymmorphic bosonization coefficients.

The low energy physics of the 1D spin-1/2 repulsive Hubbard model at half filling is known to be described by the SU(2)_1 Wess-Zumino-Witten (WZW) model, which is the same as the low energy theory of the spin-1/2 AFM Heisenberg model (for details, see Ref. 49 and Appendix C). Hence, the weak coupling repulsive Hubbard model can be used to mimic the low energy physics of the Kitaev-Heisenberg-Gamma model at the hidden AFM point (i.e., \( K + 2J = 0, \Gamma = 0 \)) in the four-sublattice rotated frame. Then \( K + 2J \) and \( \Gamma \) can be treated as perturbations to the repulsive Hubbard model.

Here we make some comments on the reasons why a fermion model has to be introduced for an RG treatment, and the limitations of the method. We first emphasize that the bosonization coefficients arise from the microscopic lattice structures. Hence a perturbation in the low energy sector cannot capture these bosonization coefficients, and the physics at the “Planck scale” of the lattice has to be involved. It seems that there is still hope since the spin-1/2 Heisenberg model is an integrable system solvable by the Bethe ansatz method, which is applicable to any energy scale. However, a perturbation on the Heisenberg model is analytically intractable since Bethe ansatz is a very intricate method, not suitable for perturbative calculations.

On the other hand, it is standard to perform perturbative calculations based on the free fermion models. Therefore, in the weak coupling limits, i.e., when the Hubbard interaction, the combination \( K + 2J, \) and the Gamma interaction are all small, an RG analysis can be applied in the vicinity of the free fermion fixed point. Notice that this directly implies the limitation of the method. Our RG analysis is only qualitative, since the model is changed from a pure spin model to a fermion model. However, this RG analysis is able to provide explanations for the origin of the bosonization coefficients, justifying the proposed nonsymmorphic bosonization formulas in Eq. (7). It is able to give predictions on the signs and order of magnitudes of the bosonization coefficients.

We start from the following fermion model in the four-sublattice rotated frame,
\[ H_F = H_0 + H_{int}, \tag{11} \]
in which
\[ H_0 = -t \sum_{<ij>,\alpha} (c_{i\alpha}^\dagger c_{j\alpha} + \text{h.c.}) - \mu \sum_{i\alpha} c_{i\alpha}^\dagger c_{i\alpha}, \]
\[ H_{int} = H_U + H_4, \tag{12} \]
where
\[ H_U = U \sum_i n_{\uparrow_i} n_{\downarrow_i}, \]
\[ H_4 = \sum_{<ij> \in \gamma \text{ bond}} \left[ (K + 2J) S_i^\alpha S_j^\gamma + \epsilon(\gamma) \Gamma (S_i^\alpha S_j^\beta + S_i^\beta S_j^\alpha) \right]. \tag{13} \]

At half-filling and for a repulsive \( U, \) \( H_0 + H_U \) reproduces the SU(2)_1 WZW model in the low energy limit (see Ref. 49 and Appendix C). Then by adding \( H_4, \) the low energy physics of the Kitaev-Heisenberg-Gamma model is recovered.

The partition function for \( H_F \) is given by
\[ Z = \int D[c, c^\dagger] e^{-S}, \tag{14} \]
where
\[ S = \int d\tau \sum_{i\alpha} c_{i\alpha}^\dagger \partial_\tau c_{i\alpha} + H_0 + H_{int}. \tag{15} \]

The goal is to compute the spin correlation functions \( G_{i\alpha,j\beta}(\tau, n) \)
\[ G_{i\alpha,j\beta}(\tau, n) = \langle S_i^\alpha(0) S_j^{\beta+4n}(\tau) \rangle \]
\[ = \frac{1}{Z} \int D[c, c^\dagger] S_i^\alpha(0) S_j^{\beta+4n}(\tau) e^{-S} \tag{16} \]
in which $\tau$ is the imaginary time, $i, j \in \{1, 2, 3, 4\}$, and
\[
S_i^\alpha = \sum_{a,b} \frac{1}{2} \epsilon_{\alpha}^{\beta} \sigma_{ab}^{\nu} c_{ia}^\dagger c_{ib},
\]
where $a, b = \uparrow, \downarrow$.

\[\text{(17)}\]

We note that upon integrating over the fast modes in a momentum shell, $H_{int}$ renormalizes the spin operators. In fact, by separating the fast and slow modes, we obtain
\[
G_{ia,j\beta}(\tau,n) = \frac{1}{Z_<} \int D[c_<, c_<^\dagger] e^{-S_{eff,<}} \langle (1 - \int d\tau dx H_{int,>,<}) S_i^\alpha(0) S_j^\beta_{j+4n}(\tau) \rangle, \]
in which $H_{int,>,<}$ represents the mixing term between the fast and slow modes, $\langle ... \rangle_>$ is defined as
\[
\langle ... \rangle_> = \frac{1}{Z_>} \int D[c_>, c_>^\dagger] e^{-S_{eff,>}} \langle ... \rangle,
\]
and only first order renormalization is taken into account for the spin operators. Eq. (18) leads to a set of coupled Callan-Symanzik equations, which can be solved to determine the behaviors of the correlation functions.

The interactions and the spin operators are represented by the diagrams in Fig. 3 and Fig. 4 respectively. In particular, Fig. 3 represents $(K + 2J)S_i^\alpha S_j^\beta + \epsilon(\gamma)\Gamma(S_i^\alpha S_j^\beta + S_i^\beta S_j^\alpha)$ where $<ij> = \gamma$. There are two diagrams which contribute to the contractions between $H_{int,>,<}$ and the spin operators as shown in Fig. 5 and Fig. 6. It is clear that Fig. 5 introduces a renormalization of the spin operators, whereas on the other hand, Fig. 6 produces new terms along the RG flow, which are of the forms $c_i^\dagger \sigma^\lambda c_j$ where $i = j \pm 1$. Although $c_i^\dagger \sigma^\lambda c_j$ is not of the form of an on-site spin operator, it becomes indistinguishable from a spin operator in the low energy limit when the difference between adjacent sites is smeared out. Later in Sec. IV B we will see that the value of the diagram in Fig. 6 vanishes. However, we still include it here from a conceptual consideration, and in addition, if the Hamiltonian in Eq. (1) contains beyond next-nearest neighbor terms (which is always the case in real materials), the diagram in Fig. 6 indeed contributes. We note that the set of coupled Callan-Symanzik equations for the correlation functions to the one-loop level can be obtained from the two diagrams in Fig. 5 and Fig. 6.

Here we take an alternative route for later convenience. Instead of considering the Callan-Symanzik equations, we introduce the following set of magnetic fields into the...
fermion Hamiltonian where $F_h$ around a linearization of the free fermion spectrum where the four sites within a unit cell are smeared and

$$n \in \mathbb{N} \quad \pi \quad \text{s}$$

in which $n$ is the index of the unit cell; $i$ and $j$ are site indices within a unit cell, and the $h_{ij}^\alpha (\tau, n)$ terms are inserted since they can be generated upon RG flow as a result of the diagram in Fig. 6. The spin correlation functions can be obtained from the functional derivatives as

$$\langle S^\alpha_\beta (\tau, n) S^\beta_\alpha (\tau', n') \rangle = \frac{\partial^2 F}{\partial h^\alpha_\beta (\tau, n) \partial h^\beta_\alpha (\tau', n')},$$

where $F = -\ln Z$ is the free energy.

We will determine the RG flow equations for the scaling fields $h^\alpha_\beta (\tau, n)$ and $h^\alpha_\beta (\tau, n)$. In Eq. (12), the free fermion Hamiltonian $H_0$ is gapless at $\pm k_F = \pm \pi/(2a)$, giving rise to left mover $c_L \alpha$ and right mover $c_R \alpha (a = \uparrow, \downarrow)$ at low energies, where $c_L \alpha$ and $c_R \alpha$ are the fermion annihilation operators for the left and right movers, containing Fourier components with wavevectors close to $-k_F$ and $k_F$, respectively. Then in the low energy limit, the wavevectors in the spin operators are either close to zero or $\pi$, corresponding to intra-mover and inter-mover contributions. Keeping only the low energy modes, the spin operator $S^\alpha (\tau)$ at smeared position $r$ and time $\tau$ can be written as

$$S^\alpha (\tau) \sim S^\alpha_\upsilon (\tau, r) + (-)^r S^\alpha_\sigma (\tau, r),$$

in which the uniform component $S^\alpha_\upsilon (\tau, r)$ and staggered component $S^\alpha_\sigma (\tau, r)$ are given by

$$S^\alpha_\upsilon = \frac{1}{2} (c_L^\dagger \sigma^\alpha c_L + c_R^\dagger \sigma^\alpha c_R),$$

$$S^\alpha_\sigma = \frac{1}{2} (c_L^\dagger \sigma^\alpha c_R + c_R^\dagger \sigma^\alpha c_L),$$

where $c_\lambda = (c_{\lambda \uparrow}, c_{\lambda \downarrow})^T (\lambda = L, R)$ and both $S^\alpha_\upsilon$ and $S^\alpha_\sigma$ are smooth functions of $r$ (i.e., no Fourier components with a wavevector far from zero). Here we note that since $h^\alpha_\beta (\tau, n)$ is defined every four sites, the zero- and $\pi$-wavevector components cannot be distinguished in $h^\alpha_\beta (\tau, n)$ or $h^\alpha_\beta (\tau, n)$ since both components are smooth in $n$.

Finally we make a comment on the energy scales in the problem. There are five characteristic energy scales $\Lambda_0, \Lambda_\upsilon, \Lambda_\sigma, m_\upsilon$, and $E$, where $\Lambda_0 \sim 1/\alpha$ is the UV cutoff of the lattice structure, $\Lambda_\upsilon \sim 1/(4a)$ is the energy scale where the four sites within a unit cell are smeared and can no longer be clearly distinguished, $\Lambda_\sigma$ is the energy scale where a linearization of the free fermion spectrum around $\pm k_F$ can be performed, $m_\upsilon \sim e^{-\text{const.} t / U}$ is the charge gap due to the repulsive Hubbard term, and $E$ is the energy scale of the correlation functions which we are eventually interested in. The hierarchy of the energy scales is clearly

$$\Lambda_0 \gg \Lambda_\upsilon \gg \Lambda_\sigma \gg m_\upsilon \gg E.$$

We note that below $\Lambda_\upsilon$, the fermion has an emergent Lorentz symmetry, and is fractionalized into a $U(1)$ charge boson and an $SU(2)_\upsilon$ spin boson. When the energy is further lowered below $m_\upsilon$, the charge boson is gapped, and we are left with only spin degrees of freedom $J^\upsilon$ and $N^\upsilon$. We also note that since the microscopic lattice structure is lost at $\Lambda_\upsilon$, our RG analysis stops at an energy scale $\sim \Lambda_\upsilon$.

IV. RG FLOW EQUATIONS

In this section, we derive the RG flow equations for the scaling fields $h^\alpha_\beta (\tau, n)$ and $h^\alpha_\beta (\tau, n)$ from the diagrams in Fig. 6 and Fig. 5.

A. Flow equations from the diagram in Fig. 5

Let’s first consider the diagram in Fig. 5. It is nonvanishing when $\nu = \alpha$, and renormalizes $h^\alpha_\beta$. Suppose we lower the cutoff from $\Lambda_0/\nu$ to $\Lambda_0/\nu' = b + \Delta b$ with $0 < \Delta b \ll 1$. The perturbation process in Fig. 5 gives rise to the following term in the action

$$\lambda_{ij} \delta_{\nu\alpha} \Delta \ln b \int d\tau \sum_n h^\alpha_\beta (\tau, n) S^\nu_\beta (\tau, \tau + 4\Delta),$$

leading to a renormalization of $h^\alpha_\beta$ by $h^\alpha_\beta$, where $\Delta \ln b = \Delta b / b$. Define the free fermion Green’s function $G(k)$ as

$$G(k) = \frac{1}{i \omega - \epsilon(k)},$$

in which $k = (i \omega, \vec{k})$ where $\omega$ is Matsubara frequency and $\vec{k}$ is the wavevector in space (we define the spatial wavevector as a vector to distinguish it from the spacetime combined index $k$, even though the system is 1D and $\vec{k}$ is in essence a scalar), and $\epsilon(k)$ is the free fermion dispersion which includes the chemical potential term. The coefficient $\lambda_{ij}$ can be derived as

$$\lambda_{ij} \Delta \ln b =$$

$$- \frac{\Delta b}{8} \sum_{m=1}^a e^{-i \frac{\pi}{2a}(j-l)} \int_{\Lambda_0/b'}^{\Lambda_0/b} d^2 k G(k) G(k + \frac{\pi}{2a} \hat{m} \hat{x}),$$

where $a$ is the lattice spacing, and $\hat{x}$ is the unit vector in the spatial direction. We note that because of the translation and inversion symmetries of the free fermion theory, $\lambda_{ij}$ satisfies the following relations

$$\lambda_{ij} = \lambda_{i+l,j+l} = \lambda_{-i,-j} = \lambda_{i,j+4},$$

(28)
where \( l \in \mathbb{Z} \).

We briefly describe the derivation of \( \lambda_{jl} \). Detailed derivations are included in Appendix D. The Fourier transforms of the fermion operator and the scaling field are defined as

\[
c_\sigma(k) = \frac{1}{\sqrt{N\beta}} \int d\tau \sum_{j=1}^N c_{\sigma j}(\tau) e^{i(\omega \tau - \vec{k} \cdot \vec{x})},
\]

and

\[
h^{\sigma}_\alpha(q) = \frac{1}{\sqrt{N\beta}} \int d\tau \sum_{n=1}^{N/4} h^{\sigma}_\alpha(\tau, n) e^{i\omega \tau - q 4 \alpha n \vec{a}_x},
\]

in which \( N \) is the system size, \( \beta \) is the inverse of the temperature, \( j \) in Eq. (29) is summed over all sites in the chain, and \( n \) in Eq. (30) is summed over the unit cells. Integrating over the fast modes in the momentum shell and using momentum conservations in the free fermion model, the expression of the diagram in Fig. 5 is given by

\[
\begin{align*}
\frac{1}{4} & \sum_{m=1}^4 \sum_{k'q'} e^{i \vec{q} \cdot \vec{a}_x} e^{i \vec{q}' \cdot \vec{a}_x} h^{\sigma}_\alpha(-q') c_\sigma(k + q' + \frac{\pi}{2a} \vec{m} \vec{x}) \frac{1}{2} \sigma^\alpha c(k) \\
\times & e^{-i \vec{q}' \cdot (j-l) \vec{a}_x} \frac{1}{4N\beta} \sum_{m=1}^4 \sum_{k'} e^{-i \vec{q'} \cdot (m+\vec{m}) (j-l)} \\
\times & \langle c'(k' + \frac{\pi}{2a} (m+\vec{m}) \vec{x}) c^\dagger (k + \frac{\pi}{2a} \vec{m} \vec{x}) \rangle \frac{1}{2} \sigma^\alpha(c(k' - q') c_t),
\end{align*}
\]

in which \( q' \) in \( h^{\sigma}_\alpha(-q') \) satisfies \( |q'| \sim 0 \), since \( h^{\sigma}_\alpha(n) \) is a smooth function of \( n \). In Eq. (31), the factor \( e^{-i \vec{q}' \cdot (j-l) \vec{a}_x} \) can be set as 1 since it is a slowly varying variable. Comparing with the following Fourier representation of the magnetic field term in the action

\[
\int d\tau \sum_n h^{\sigma}_\alpha(\tau, n) S^{\sigma}_n(\tau) =
\frac{1}{4} \sum_{kq} e^{i \vec{q} \cdot \vec{a}_x} e^{i \vec{q}' \cdot \vec{a}_x} h^{\sigma}_\alpha(-q) c_\sigma(k + \frac{\pi}{2a} m \vec{x}) \frac{1}{2} \sigma^\alpha c(k - q),
\]

it can be seen that Eq. (31) is of the form in Eq. (25), which renormalizes \( h^{\sigma}_\alpha \), in which \( \lambda_{jl} \) is given by Eq. (27).

Eq. (27) is the desired expression for the coefficients \( \lambda_{jl} \)’s in the RG flow equations. An analytic expression of \( \lambda_{jl} \) is difficult, so we will turn to numerical calculations. The numerical value of \( \lambda_{jl} \) relies on the underlying free fermion band structure \( e(k) \), but the essential physics does not depend on the details of the band structure. Hence, the precise form of the band structure is not essential in our RG treatment. The free fermion term \( H_0 \) in Eq. (12) has a \( -t \cos(\vec{k} \cdot \vec{x}) \) dispersion. For simplicity, we modify the dispersion to a linear form, as

\[
e(k) = \nu (|\vec{k}| - \Lambda_0),
\]

where \( \nu = t/\Lambda_0 \), and \( \Lambda_0 = \pi/(2a) \). The figure for the spectrum in Eq. (33) is shown in Fig. 7(a). The dispersion is essentially a Dirac fermion as shown in Fig. 7(b), in which the positions of the two gapless Fermi points are combined.

Next we evaluate the value of \( \lambda_{jl} \) along RG flow. Although the Dirac fermion has a cutoff \( \Lambda_0 \) in momentum space as shown in Fig. 7(b), the value of the Matsubara frequency at zero temperature is continuous and can extend to infinity. Therefore, RG starts with an initial cutoff \( \Lambda_i \sim \infty \) in the frequency-momentum space, and stops at \( \Lambda_s \sim \Lambda_0/4 \) as explained before. The values of \( \lambda_{jl} \) in general depend on the cutoff \( \Lambda = \Lambda_0/b \) where \( \Lambda_0 = \pi/(2a) \). We note that \( b \) can be smaller than 1 since the value of the Matsubara frequency can take large values.

According to Fig. 7(b), the modes satisfying \( \frac{\Lambda_0}{\nu \sqrt{\Delta_{\vec{k}}}} \leq \sqrt{(\omega/\nu)^2 + (|\vec{k}| - \Lambda_0)^2} \leq \frac{\Lambda_0}{\nu} \) are integrated over. The frequency and wavevector in the momentum shell can be parametrized as

\[
\omega/\nu \Lambda_0 = \frac{1}{b} \cos(\theta), \quad |\vec{k}| - \Lambda_0 = \frac{1}{b} \sin(\theta),
\]

where for each value of \( |\vec{k}| - \Lambda_0 \in [-\Lambda_0, \Lambda_0] \), we have both the left mover and the right mover. We note that when \( b < 1 \), \( \theta \) cannot take all values in \([0, 2\pi]\), since \( -\Lambda_0 \leq |\vec{k}| - \Lambda_0 \leq \Lambda_0 \). On the other hand, when \( b > 1 \), \( \vec{k} \) cannot take all values in \([-\pi/a, \pi/a]\), since some of the \( \vec{k} \)’s have been integrated over.
where \( b \) region operators, their flows can be safely neglected between the

\[ f(\nu, m, \theta, b) \]

\[ \times \frac{1}{[\cos \theta - b \cos(\theta + \nu)]} \times \frac{1}{[\cos \theta - b \cos(\theta + \nu + m)]}, \]

in which \( \nu = 1 \) and \( -1 \) corresponds to the right and left movers in Fig. 7 (b), respectively: \( f(\nu, m, \theta, b) \) is defined as

\[ f(\nu, m, \theta, b) = 1, \text{ if } |b^{-1} \sin \theta|, |e(b^{-1} \sin \theta + \nu)|, \]

\[ |e(b^{-1} \sin \theta + \nu + m)| \leq \min\{1, b^{-1}\}, \]

\[ f(\nu, m, \theta, b) = 0, \text{ otherwise}, \]

imposing the condition that the magnitude of the spatial wavevector cannot exceed the cutoff; \( \tilde{\epsilon} \) is defined as

\[ \tilde{\epsilon}(x) = |\text{mod}(x, 4)| - 1, \]

where \( -2 \leq \text{mod}(x, 4) \leq 2 \).

Next we write down the flow equations for \( h_n(x) \), in which \( x \) is the flow parameter, defined as \( \Lambda(x) = \Lambda_0/b \) where \( \Lambda_0 \) is the cutoff at the stage of the flow in consideration. Since we are only interested in the \( U(1) \) breaking effects, we neglect the renormalizations of the scaling fields due to the Hubbard term. Although the Hubbard term also renormalizes the scaling fields, such renormalizations are SU(2) symmetric, which does not affect the conclusions on \( U(1) \) breaking effects in the bosonization coefficients on a qualitative level. We will also neglect the flows of the coupling constants \( K + 2J \) and \( \Gamma \). The reason is as follows.

Next we consider the diagram in Fig. 6. This diagram gives rise to

\[ \lambda_{i\mu} \Delta \ln b \int d\tau \sum_n h_i^{\mu}(\tau) \frac{1}{2} \epsilon_i^{+4n} \sigma^\alpha \sigma^\beta \epsilon_i^{+4n}, \]

which leads to a renormalization of \( h_i^{\mu \alpha \beta \gamma} \), where the multiplication \( \mu \cdot \nu \) (\( \mu, \nu = 1, 2, 3, 4 \)) is defined as \( x \cdot y = x \cdot z = z \cdot x = y \cdot z = z \cdot y = x \). The coefficient \( \lambda_{ij} \) can be derived as

\[ \lambda_{i\mu} \Delta \ln b = \frac{a}{8} \sum_m e^{i\tilde{\tau}_m(i-\tilde{\tau})} \int_{\Lambda/b} d^2k' \times e^{-i(k' \cdot (i-j)a^z)} G(k') G(k' + \frac{\pi}{2a} m a^z). \]

Details of the derivation of Eq. (40) is included in Appendix D.

We demonstrate that the integration in Eq. (40) vanishes when \( j = i \pm 1 \), which applies to our case. Notice that for \( j = i \pm 1 \),

\[ e^{-i(k' + \frac{\pi}{2} a^z \cdot (i-j)a^z)} = e^{-i(k' \cdot (i-j)a^z)} \]

Then performing change of variables \( (\omega \rightarrow -\omega, k' \rightarrow k' + \frac{\pi}{2} a^z) \) (the change of variable for \( \omega \) is legitimate since the \( \omega \) also lies in the momentum shell) and using \( \epsilon(k') = -\epsilon(-k') \), it can be seen that the integration in Eq. (40) changes sign, hence \( \lambda_{ij} = -\lambda_{ij} = 0 \). We note that when the Hamiltonian contains beyond nearest neighbor terms (e.g., \( |j - i| = 2 \)), the integration in Eq. (40) no longer vanishes, and the diagram in Fig. 6 will contribute.
Because of the vanishing of $\lambda_{ij}$, the RG flow equations of $\lambda_{ij}$ are
\[
\frac{dh_{ij}^\mu}{d\ln b} = h_{ij}^\mu, \tag{42}
\]
where $j = i \pm 1$. Notice that initially $h_{ij}^{(0)\mu} = 0$ at the beginning of the RG flow, hence the solution of Eq. (42) is
\[
h_{ij}^{(0)\mu} (b) = 0. \tag{43}
\]

C. Solving the RG flow equations

The RG flow equations for $h_{ij}^\mu$ have already been solved in Eq. (43). To obtain $h_{ij}^\mu (b)$, the coupled RG flow equations in Eq. (38) need to be solved, which is a difficult problem. Here we make the assumption that both $K + 2J$ and $\Gamma$ are very small and only keep up to their first order terms. With this approximation, all the terms on the right hand side of the flow equations proportional to $K + 2J$ or $\Gamma$ can be replaced with $b h_{ij}^{(0)}$, where $h_{ij}^{(0)}$ is the initial value (i.e., bare field) at the beginning of the RG flow $b_0$. Here we note that $b_0$ in principle should be taken as $b_0 = 0$ since the Matsubara frequency can take infinite values.

Within the first order approximation, we obtain the following typical flow equation,
\[
\frac{dh(x)}{dx} = h(x) + \lambda(x)e^x, \tag{44}
\]
where $x = \ln b$, and $\lambda$ is on order of $K + 2J$ or $\Gamma$. Let $h = ye^x$, Eq. (44) can be rewritten as
\[
\frac{dy}{dx} = \lambda, \tag{45}
\]
which can be easily solved as
\[
y = y_0 + \int dx \lambda(x). \tag{46}
\]
Hence the solution of Eq. (44) is
\[
h(b) = h(0) + \int d\ln b \cdot \lambda(b)]. \tag{47}
\]
Using Eq. (47), Eq. (38) can be solved as
\[
h_{ij}^\mu (b) = b [h_{ij}^{(0)\mu} - (K + 2J) \int d\ln b \sum_{\gamma, k} (\delta_{\mu\gamma} \lambda_{jk} h_{k}^{(0)\gamma} + \delta_{ij} \lambda_{ik} h_k^{(0)\gamma})
- \Gamma \int d\ln b \sum_{\gamma, k} \epsilon(\gamma) (\delta_{\mu\alpha} \lambda_{jk} h_k^{(0)\beta} + \delta_{ij} \lambda_{ik} h_k^{(0)\alpha}
+ \delta_{\mu\beta} \lambda_{jk} h_k^{(0)\alpha} + \delta_{ij} \lambda_{ik} h_k^{(0)\beta})], \tag{48}
\]
in which $\gamma = x, y, \bar{x}, \bar{y}$; $\alpha \neq \beta \neq \gamma$; the spin direction index $\bar{x}$ (and $\bar{y}$) is identified with $x$ (and $y$) in the Kronecker delta and the scaling field; $<i j> = \gamma$; $i < j$; $1 \leq i, j \leq 4$; $5$ is identified with $1$; and $h_{ij}^{(0)\mu} = 0$ is used.

V. BOSONIZATION COEFFICIENTS FROM RG FLOW EQUATIONS

In this section, we derive the nonsymmetric bosonization coefficients from the solutions of the RG flow equations. Since $h_{i,i+\pm 1}^{(0)}$’s are all zero as shown in Eq. (43), we will focus on the terms involving $h_{ij}^\mu$.

A. The uniform and staggered scaling fields at low energies

Below the energy scale $\Lambda_s$, the differences among the sites within a unit cell are smeared out and our RG analysis stops. At this stage, the coupling to the scaling fields is
\[
- \sum_n \sum_{\alpha=x,y,z} \int d\tau h_n^\alpha (b; \tau, n) S_{n+4n} (\tau), \tag{49}
\]
in which $b > \Lambda_0 / \Lambda_s$. In addition, the $K + 2J$ term becomes indistinguishable from the U(1) symmetric interaction $1/2 (K + 2J) \sum_{\gamma, k} [S_\gamma S_{k+1} + S_k S_{k+1}]$, and the $\Gamma$ interaction cancels due to the $\epsilon(\gamma)$ factor in Eq. (3). Therefore, below the scale $\Lambda_s$, although the RG flow continues to renormalize the scaling fields, such renormalizations respect the U(1) symmetry and there is no further U(1) breaking effect. In view of this, for the purpose of a qualitative understanding of the U(1) breaking effects in the bosonization coefficients, we will not discuss the flow equations below $\Lambda_s$, bearing in mind that they only give rise to some overall U(1) preserving factors.

When the cutoff is further lowered below $\Lambda_L$, the only spin degrees of freedom are $S^a_1$ and $S^a_{2}$ defined in Eq. (23), since the wavevectors far from 0 and $\pi$ have all been integrated out. We make a comment on the low energy field theory at the scale $\Lambda_L$. As explained in Eq. (24), below $\Lambda_L$, the fermion model can be approximated as a 1+1-dimensional Dirac fermion, and the spin-charge separation is applicable. The low energy field theory contains a spin part and a charge part. The charge Hamiltonian has a $\cos(\sqrt{8\tau} \phi)$ term due to the repulsive Hubbard interaction where $\phi$ is the charge boson, which eventually opens a charge gap at the energy scale $m_c$ (where the mass acquires the same order of magnitude as the cutoff). The spin Hamiltonian is of the XXZ type, since the smeared $K + 2J$ interaction lowers the symmetry of the low energy Hamiltonian from SU(2) to U(1). Clearly, the low energy theory has an emergent U(1) symmetry below the energy scale $\Lambda_L$. It is worth to mention that although U(1) breaking renormalizations have already stopped at the scale $\Lambda_s$, it is not legitimate to talk about a low energy theory at $\Lambda_s$, since $\Lambda_s \sim \Lambda_0 / 4$ is still in the high energy region.

To express Eq. (49) in terms of $S^a_1$ and $S^a_{2}$ when the energy scale is below $\Lambda_L$, we should first project Eq. (49) to left and right movers of the fermions, and then rewrite
the expression using $S^\alpha_j$ and $S^\alpha_s$. Clearly, the projection of $S^\alpha_{j+4n}$ is given by

$$S^\alpha_{j+4n}(n) = \frac{1}{2}(c^+_l \sigma^\alpha c_R + c^+_R \sigma^\alpha c_L)$$

$$+ (-)^{\frac{1}{2}}(c^+_l \sigma^\alpha c_R + c^+_R \sigma^\alpha c_L).$$

(50)

Plugging Eqs. (23,50) into Eq. (49), we arrive at

$$- \sum\alpha \int d\tau dx (h^\alpha_{u} J^\alpha + h^\alpha_{s} N^\alpha),$$

(51)

in which the uniform and staggered scaling fields $h^\alpha_{u}, h^\alpha_{s}$ are given by

$$h^\alpha_{u} = \sum_{j=1}^{4} h^\alpha_{j},$$

$$h^\alpha_{s} = \sum_{j=1}^{4} (-)^{j} h^\alpha_{j},$$

(52)

B. Derivations of the bosonization coefficients

Plugging Eq. (48) into Eq. (52), $h^\alpha_{u}$ and $h^\alpha_{s}$ (defined below the scale $\lambda_L$) can be expressed in terms of $h^\alpha_{j(0)}$ as

$$h^\alpha_{u} = \sum_{\nu=x,y,z} \sum_{l=1}^{4} D_{l}^{\alpha\nu} h_{l(0)}^{(0)\nu},$$

$$h^\alpha_{s} = \sum_{\nu=x,y,z} \sum_{l=1}^{4} (-)^{l} C_{l}^{\alpha\nu} h_{l(0)}^{(0)\nu},$$

(53)

in which $D_{l}^{\alpha\nu}$ and $C_{l}^{\alpha\nu}$ are some numerical factors. Notice that the low energy fields $J^\alpha$ and $N^\alpha$ live at an energy scale below $m_c$ where the charge sector has been gapped out, leaving only the spin degrees of freedom. When the energy scale is further lowered from $\Lambda_L$ to below $m_c$, $S^\alpha_u$ and $S^\alpha_s$ become just $J^\alpha$ and $N^\alpha$, respectively, since $S^\alpha_u$ ($S^\alpha_s$) and $J^\alpha$ ($N^\alpha$) both correspond to the zero- ($\pi$-) wavevector component of the low energy spin operator $S^\alpha (\tau)$ defined in Eq. (22). As mentioned earlier, the RG flow between $\Lambda_L$ and $m_c$ respects the emergent U(1) symmetry. Hence, up to some additional U(1) symmetric renormalization factors, the coupling to scaling fields in Eq. (51) becomes

$$- \sum\alpha \int d\tau dx (h^\alpha_{u} J^\alpha + h^\alpha_{s} N^\alpha)$$

(54)

below the scale $m_c$.

Recall that performing functional derivatives $\partial / \partial h^\alpha_{u}$, $\partial / \partial h^\alpha_{s}$, and $\partial / \partial h^\alpha_{u}$ on the free energy can give the correlation functions involving $S^{\alpha}_u$, $J^\alpha$, and $N^\alpha$, respectively. Using

$$\frac{\partial}{\partial h_{(0)\nu}^{(0)}} = \sum_{\alpha=x,y,z} \left[ \frac{\partial h^\alpha_{u}}{\partial h_{l}^{(0)\nu}} \frac{\partial}{\partial h^\alpha_{u}} + \frac{\partial h^\alpha_{s}}{\partial h_{l}^{(0)\nu}} \frac{\partial}{\partial h^\alpha_{s}} \right]$$

(55)

we see from Eq. (53) that

$$D_{l}^{\alpha\nu} = \frac{\partial h^\alpha_{u}}{\partial h_{l}^{(0)\nu}}, \quad C_{l}^{\alpha\nu} = \frac{\partial h^\alpha_{s}}{\partial h_{l}^{(0)\nu}}.$$  

(56)

In particular, it can be seen from Eq. (55) that $D_{l}^{\alpha\nu}$ and $C_{l}^{\alpha\nu}$ in Eq. (53) are related to the bosonization coefficients defined in Eq. (7) by

$$D_{l}^{\alpha\beta} = \sum_{\nu=x,y,z} E_{ij}^{\alpha\nu} h_{j(0)}^{(0)\nu}, \quad C_{l}^{\alpha\beta} = \sum_{\nu=x,y,z} E_{ij}^{\alpha\nu} h_{j(0)}^{(0)\nu},$$

(59)

in which the explicit expressions of the coefficients $E_{ij}^{\alpha\nu}$ can be read from Eq. (48). Plugging Eq. (58) into Eq. (59) and comparing with Eqs. (53,57), we obtain

$$D_{l}^{\alpha\beta} = \sum_{\nu=x,y,z} E_{ij}^{\alpha\nu} h_{j(0)}^{(0)\nu}, \quad C_{l}^{\alpha\beta} = \sum_{\nu=x,y,z} (-)^{i+j} E_{ij}^{\alpha\nu},$$

(59)

which give the bosonization coefficients via Eq. (57).

From Eq. (59), the explicit expressions of the ten bosonization coefficients up to first orders in $K+2J$ and $\Gamma$ can be derived as

$$a_D = b[1 - (K+2J) \int d\ln b \cdot (\lambda_{11} + \lambda_{21} + \lambda_{31} + \lambda_{41})]$$

$$b_D = 0$$

$$c_D = b \Gamma \int d\ln b \cdot (\lambda_{11} - \lambda_{21} - \lambda_{31} + \lambda_{41})$$

$$h_D = b \Gamma \int d\ln b \cdot (\lambda_{11} - \lambda_{21} + \lambda_{31} + \lambda_{41})$$

$$i_D = b,$$

(60)

and

$$a_C = b[1 - (K+2J) \int d\ln b \cdot (\lambda_{11} - \lambda_{21} + \lambda_{31} - \lambda_{41})]$$

$$b_C = 0$$

$$c_C = b \Gamma \int d\ln b \cdot (\lambda_{11} + \lambda_{21} - \lambda_{31} - \lambda_{41})$$

$$h_C = b \Gamma \int d\ln b \cdot (\lambda_{11} + \lambda_{21} - \lambda_{31} - \lambda_{41})$$

$$i_C = b,$$

(61)

in which $\lambda_{ij}$’s are functions of $b$ as determined by Eq. (35).

It can be seen from Eqs. (60,61) that up to first order in $K+2J$ and $\Gamma$, the coefficients $b_D$ and $b_C$ vanish. In
fact, they start to appear at second order. Take $b_D$ as an example. It can be observed from the flow equations that $h_0^j$ contributes to the flow of $h_1^j$, and $h_1^j$ contributes to the flow of $h_2^j$. As a result, $h_2^j$ is affected by $h_0^j$, eventually leading to a nonzero $b_D$. However, this is clearly a second order effect. Also notice that in Eqs. (60-61), there are the relations $c_D = h_D$, $c_C = h_C$. However, these equalities are not expected to hold when higher order terms are included.

We make some comments on the effects of the RG flow below the energy scale $\Lambda_L$. The scaling fields $h_0^\alpha (\eta = u, s$ and $\alpha = x, y, z)$ are related to $h_0^\alpha (b_L)$ ($b_L = \Lambda_0/\Lambda_L \ll b$) via the following relations

$$h_0^\alpha (b) = \sum_{\beta} M_{\alpha \beta}^{(\eta)} h_0^\beta (b_L),$$

(62)
in which the matrix $M^{(\eta)}$ is a function of $b$ (for fixed $b_L$) and has U(1) symmetry since the U(1) breaking renormalization along the RG flow has already stopped at the scale $\Lambda_2$ (which is greater than $\Lambda_L$). Using the chain rule of partial derivatives

$$\frac{\partial}{\partial h_1^{(0)\nu}} = \sum_{\eta = u, s} \sum_{\alpha, \beta = x, y, z} \frac{\partial h_0^\alpha (b_L)}{\partial h_1^{(0)\nu}} \frac{\partial h_0^\alpha (b)}{\partial h_0^\beta (b_L)} \frac{\partial}{\partial h_0^\beta (b_L)},$$

(63)
we see that the matrices $D_1 (b)$, $C_1 (b)$ are related to $D_1 (b_L)$, $C_1 (b_L)$ via

$$D_1 (b) = D_1 (b_L) (M^{(u)})^T,$n$$

$$C_1 (b) = C_1 (b_L) (M^{(s)})^T.$$

(64)

When $b$ satisfies $\Lambda_0 / b < m_c$, Eq. [63] produces the bosonization formulas, and $D_1 (b)$, $C_1 (b)$ become the matrices of bosonization coefficients in Eq. [7]. It is clear from Eq. [64] that all the bosonization coefficients $D^{(\alpha \beta)}_1$, $C^{(\alpha \beta)}_1$ are affected by the RG flow below $\Lambda_L$, though in a U(1) invariant manner. For example, in the special SU(2) case (i.e., the matrices $M^{(\eta)}$ have SU(2) symmetry, not just U(1) symmetry, which applies to the SU(2)_1 line in Fig. 2), $D^{(\alpha \beta)}_1 = r^{(u)} D^{(\alpha \beta)}_1 (b_L)$ and $C^{(\alpha \beta)}_1 = r^{(s)} C^{(\alpha \beta)}_1 (b_L)$ acquire an overall renormalization factor $r^{(u)}$ and $r^{(s)}$, respectively, where $M_{11}^{(\alpha \beta)} = r^{(u)} \delta_{\alpha \beta}$ and $M_{12}^{(\alpha \beta)} = r^{(s)} \delta_{\alpha \beta}$.

C. Values of the bosonization coefficients

From Eqs. (60-61), it can be observed that $a_D, a_C \sim O(1)$ and $c_D, h_D, c_C, h_C \sim O(1)$, whereas $b_D, b_C$ are second order in $K + 2J$ and $\Gamma$. Therefore, in the weak coupling limit (i.e., $|K + 2J|/J, |\Gamma|/J \ll 1$), we have

$$|a_C| \sim |a_D| \gg |c_D| \sim |h_D| \sim |c_C| \sim |b_D| \sim |b_C|.$$  

(65)

Table II is taken from Ref. 44, from which it can be seen that the predicted hierarchy in Eq. [65] is indeed satisfied, even though the value of $K + 2J$ is already large (equal to 1).

Next we define $\lambda_D$ and $\lambda_C$ as

$$\lambda_D (b) = \lambda_{11} (b) - \lambda_{21} (b) - \lambda_{31} (b) + \lambda_{41} (b),$$

$$\lambda_C (b) = \lambda_{11} (b) + \lambda_{21} (b) - \lambda_{31} (b) - \lambda_{41} (b).$$

(66)

Using $\lambda_{41} = \lambda_{45}$, as well as the inversion and translation symmetries, we obtain $\lambda_{21} = \lambda_{41}$, which demonstrates that up to one-loop level there is the relation

$$\lambda_D (b) = \lambda_C (b).$$

(67)

Hence it enough to consider $\lambda_C (b)$. Fig. 8 shows $\lambda_C (b)$ as a function of $\ln b$ obtained by numerically calculating the integral in Eq. [35], and it can be seen that $\lambda_C (b)$ is always negative. We note that the integral $\int d \ln b \cdot \lambda_C (b)$ converges when $b$ is integrated from 0 to $b_s \sim 4$. When $b \ll 1$, the integration in Eq. [35] is restricted within a narrow range $\theta \sim b$ due to the factor $f (\nu, m, \theta, b)$. Let $x = \ln b$, and split $\int_{-\infty}^{\infty} dx \lambda_C (x)$ as $\int_{-\infty}^{0} dx \lambda_C (x) + \int_{0}^{\infty} dx \lambda_C (x)$ where $x_s \sim \ln 4$ and $\eta \ll 1$. Since $\int_{-\infty}^{0} dx \lambda_C (x)$ goes like $\int_{-\infty}^{0} dx e^x$ which converges, we see that $\int_{-\infty}^{\infty} dx \lambda_C (x)$ is a converging integral. As a result, we conclude from Eq. (60) and Eq. (61) that RG predicts

$$c_C < 0, h_C < 0, c_D < 0, h_D < 0.$$  

(68)
D. Comparison with numerics

Next we check if the predictions in Eq. (68) are consistent with the numerical results. The method for numerically determining the signs of the bosonization coefficients has been discussed in detail in Supplementary Materials in Ref. 44. In this subsection, we follow the method in Ref. 44. We will focus on the “C” coefficients, since they correspond to $N^\alpha (\alpha = x, y, z)$ which are relevant operators and open a spin gap at low energies. Appendix C discusses the numerical determinations of the “D” coefficients, which are not successful, and the reasons remain not clear.

Throughout this subsection, we work in the four-sublattice rotated frame and take the parameters as $K + 2J = 1$, $J = -1$, $\Gamma = 0.35$ in accordance with Ref. 44. DMRG numerical simulations are performed on a system of $L = 144$ sites with periodic boundary conditions. The bond dimension $m$ and truncation error $\epsilon$ in DMRG simulations are taken as $m = 1400$ and $\epsilon = 10^{-9}$.

Applying a small staggered magnetic field $h^z$ along $z$-direction, the low energy Hamiltonian can be derived as $-h^z C_f \int dx N^z$. Since $N^z$ is a relevant operator, a spin gap opens and a nonzero expectation value ($N^z$) is developed in the low energy theory. Using the non-symmorphic bosonization formulas, the spin expectation values are

\[
\langle \hat{S}_{1+4n} \rangle = \langle N^z \rangle (a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}^z_{2+4n} \rangle = \langle N^z \rangle (a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}_{3+4n} \rangle = \langle N^z \rangle (a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}^z_{4+4n} \rangle = \langle N^z \rangle (a_C, -b_C, -c_C).
\]

(69)

Taking $h^z = 10^{-3}$, DMRG simulations are able to verify the pattern in Eq. (69), with

\[
\langle N^z \rangle h_C = -4.5 \times 10^{-4},
\]

\[
\langle N^z \rangle i_C = 0.0119.
\]

(70)

This shows that

\[
h_C/i_C = -0.0378.
\]

(71)

Notice that $i_C$ is the dominant coefficient, and we expect that it does not change sign compared with the U(1) symmetric case for the microscopic Hamiltonian (i.e., when $K + 2J = 0$ and $\Gamma = 0$). Therefore, $h_C < 0$ as determined from Eq. (71), which is consistent with the prediction in Eq. (68). In addition, Table II gives a ratio $|h_C/i_C|$ equal to 0.0380 where the values are obtained from studying spin correlation functions. It can be seen that the two approaches (magnetic field response vs. correlation functions) are fully consistent with each other.

Next applying a small staggered magnetic field $h^z$ along $x$-direction, the low energy Hamiltonian can be derived as $-h^z (a_C \int dx N^x - b_D \int dx J^y)$. Since the scaling dimension of $N^x$ is smaller than that of $J^y$, we expect that a nonzero expectation value ($N^x$) develops in the low energy theory. Then the spin expectation values can be determined as follows from the non-symmetric bosonization formulas,

\[
\langle \hat{S}_{1+4n} \rangle = \langle N^x \rangle (-a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}^z_{2+4n} \rangle = \langle N^x \rangle (a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}_{3+4n} \rangle = \langle N^x \rangle (-a_C, -b_C, -c_C),
\]

\[
\langle \hat{S}^z_{4+4n} \rangle = \langle N^x \rangle (a_C, -b_C, -c_C).
\]

(72)

Since $a_C$ is the dominant coefficient, again $a_C$ is expected to be positive. The patterns in Eq. (72) are verified by DMRG numerics, with the following values

\[
\langle N^x \rangle a_C = 0.0890,
\]

\[
\langle N^x \rangle b_C = 1.54 \times 10^{-4},
\]

\[
\langle N^x \rangle c_C = -0.00431.
\]

(73)

which give the ratios as

\[
b_C/a_C = 0.0017,
\]

\[
c_C/a_C = -0.00484.
\]

(74)

Hence the sign of $c_C$ is consistent with the prediction in Eq. (68). However, Table II gives a ratio $|c_C/a_C| = 0.189$, not consistent with the result in Eq. (74). The reason for such discrepancy is unclear, and one possibility may be the neglection of the $J^y$ term in the analysis.

VI. SUMMARY

In summary, we have performed an RG study on the origin of the U(1) breaking terms in the bosonization formulas in the Luttinger liquid phase of the one-dimensional spin-1/2 Kitaev-Heisenberg-Gamma model with an antiferromagnetic Kitaev interaction. The RG analysis provides explanations for the origin of the ten non-universal bosonization coefficients in the abelian bosonization formulas of the spin operators. It can also give predictions on the signs and order of magnitude of these bosonization coefficients. Our work is helpful to understand the rich physics related to non-symmetric symmetries in the gapless Luttinger liquid phases of the one-dimensional Kitaev spin models.

Appendix A: Explicit forms of the Hamiltonians

The Hamiltonian in the unrotated frame is two-site periodic, which has the form

\begin{align}
H_{2n+1,2n+2} &= KS_{2n+1}^xS_{2n+2}^x + \Gamma(S_{2n+1}^yS_{2n+2}^z + S_{2n+1}^zS_{2n+2}^y) + J\bar{S}_{2n+1} \cdot \bar{S}_{2n+2}, \\
H_{2n+2,2n+3} &= KS_{2n+2}^yS_{2n+3}^y + \Gamma(S_{2n+2}^zS_{2n+3}^x + S_{2n+2}^xS_{2n+3}^z) + J\bar{S}_{2n+2} \cdot \bar{S}_{2n+3}.
\end{align}

(A1)

After the four-sublattice rotation, the Hamiltonian becomes four-site periodic, given by

\begin{align}
H'_{4n+1,4n+2} &= (K + 2J)S_{4n+1}^xS_{4n+2}^x - JS_{4n+1} \cdot \bar{S}_{4n+2} + \Gamma(S_{4n+1}^yS_{4n+2}^z + S_{4n+1}^zS_{4n+2}^y), \\
H'_{4n+2,4n+3} &= (K + 2J)S_{4n+2}^yS_{4n+3}^y - JS_{4n+2} \cdot \bar{S}_{4n+3} + \Gamma(S_{4n+2}^zS_{4n+3}^x + S_{4n+2}^xS_{4n+3}^z), \\
H'_{4n+3,4n+4} &= (K + 2J)S_{4n+3}^zS_{4n+4}^z - JS_{4n+3} \cdot \bar{S}_{4n+4} + \Gamma(S_{4n+3}^yS_{4n+4}^x + S_{4n+3}^xS_{4n+4}^y), \\
H'_{4n+4,4n+5} &= (K + 2J)S_{4n+4}^yS_{4n+5}^y - JS_{4n+4} \cdot \bar{S}_{4n+5} - \Gamma(S_{4n+4}^zS_{4n+5}^x + S_{4n+4}^xS_{4n+5}^z).
\end{align}

(A2)

Appendix B: Explicit forms of the non-Abelian bosonization formulas

In the four-sublattice rotated frame, the explicit forms of the abelian bosonization formulas in the Luttinger liquid phase in Fig. 2 are given by

\begin{align}
S_{1+4n}^x &= a_D J^x + b_D J^y + h_D J^z - a_C N^x - b_C N^y - h_C N^z, \\
S_{1+4n}^y &= b_D J^x + a_D J^y - h_D J^z - a_C N^x + b_C N^y + h_C N^z, \\
S_{1+4n}^z &= c_D J^x - c_D J^y + i_D J^z - c_C N^x + c_C N^y - i_C N^z, \\
S_{2+4n}^x &= a_D J^x - b_D J^y - h_D J^z + a_C N^x - b_C N^y - h_C N^z, \\
S_{2+4n}^y &= -b_D J^x + a_D J^y - h_D J^z - a_C N^x + b_C N^y + h_C N^z, \\
S_{2+4n}^z &= -c_D J^x + c_D J^y + i_D J^z - c_C N^x + c_C N^y + i_C N^z, \\
S_{3+4n}^x &= a_D J^x + b_D J^y - h_D J^z - a_C N^x - b_C N^y + h_C N^z, \\
S_{3+4n}^y &= b_D J^x + a_D J^y + h_D J^z - a_C N^x - b_C N^y - h_C N^z, \\
S_{3+4n}^z &= -c_D J^x + c_D J^y + i_D J^z + c_C N^x + c_C N^y - i_C N^z, \\
S_{4+4n}^x &= a_D J^x - b_D J^y + h_D J^z + a_C N^x - b_C N^y + h_C N^z, \\
S_{4+4n}^y &= -b_D J^x + a_D J^y + h_D J^z - a_C N^x + b_C N^y + h_C N^z, \\
S_{4+4n}^z &= c_D J^x + c_D J^y + i_D J^z + c_C N^x + c_C N^y + i_C N^z.
\end{align}

Appendix C: Non-Abelian bosonization of 1D repulsive Hubbard model at half filling

Here we give a quick review of the non-Abelian bosonization method (for details, see Ref. [19]). The 1D spin-1/2 Dirac fermion exhibits the phenomenon of spin-charge separation and can be decomposed into an SU(2)_1 spin boson \( g \) and a U(1) charge boson \( \phi \), where the actions in real time for the SU(2) matrix \( g \) and the real scalar \( \phi \) are given by

\begin{align}
S_g &= \frac{1}{8\pi} \int d^2 x Tr(\partial_\mu g^{-1} \partial^\mu g) + \frac{1}{12\pi} \int d^3 x e^{\nu\lambda} Tr(\partial_\mu \bar{g} g^{-1} \partial_\nu \bar{g} g^{-1} \partial_\lambda \bar{g}), \\
S_\phi &= \frac{1}{2} \int d^2 x \partial_\mu \phi \partial^\mu \phi,
\end{align}

(C1)

in which \( \bar{g} \) is an extension of \( g \) from two-dimensional spacetime to three-dimensional, and the velocities in \( S_g \) and \( S_\phi \) have been absorbed into a redefinition of time. We note that because of the topological nature of the second term (i.e., WZW term) in \( S_g \), the partition function does not depend on the way of extension. In terms of \( g \) and \( \phi \), the hopping term between the left and right movers can be bosonized as follows

\[ c_L c_R^+ = \text{const.} g e^{i\sqrt{\tau} \phi}. \]
where const. is a real constant. When a repulsive Hubbard interaction $U > 0$ is introduced, $S_y$ and $S_\phi$ are changed into

$$S'_y = S_y + \frac{2U}{\tau} \int d^2 x \vec{J}_L \cdot \vec{J}_R,$$

$$S'_\phi = \frac{1}{2} \left( 1 + \frac{U}{2\pi \tau} \right) \int d^2 x \partial_\mu \phi \partial^\mu \phi - \lambda_\phi U \int d^2 x \cos(\sqrt{8\pi\phi}),$$  \hspace{1cm} (C3)

in which $\lambda_\phi > 0$ is a constant, and the WZW current operators $\vec{J}_L$ and $\vec{J}_R$ are defined as

$$\vec{J}_L = \frac{i}{4\pi} \text{Tr}(\partial_+ g \cdot g^{-1} \vec{\sigma}),$$

$$\vec{J}_R = -\frac{i}{4\pi} \text{Tr}(g^{-1} g^{-1} \partial_- \vec{\sigma}),$$  \hspace{1cm} (C4)

where $\partial_\pm = \partial_t \pm \partial_x$. It can be shown that the spin sector remains gapless since $\vec{J}_L \cdot \vec{J}_R$ is marginally irrelevant. However, a gap opens in the charge sector since the $\cos(\sqrt{8\pi\phi})$ term is relevant at low energies. The scaling of the charge gap can be solved as $m_c \sim e^{-U/(\pi t)}$.

The above analysis shows that in the weak-$U$ limit, the low energy physics of the 1D repulsive Hubbard model is described by the SU(2) WZW theory. On the other hand, we know that according to the standard second order perturbation, the large-$U$ limit reduces to the SU(2) AFM Heisenberg model. Since there is no phase transition between the weak-$U$ and large-$U$ limits, the low energy physics of the SU(2) AFM Heisenberg model is also described by the SU(2) WZW theory. This provides a nonabelian bosonization description for the low energy physics of the AFM Heisenberg model in 1D.

**Appendix D: Evaluation of Feynman diagrams**

1. **Evaluation of diagram in Fig. 5**

We need to express the interactions and the spin operators in the frequency and momentum space. The interaction term is

$$\int d\tau \sum_n S_{\beta+4n}^0(\tau) S_{\beta+4n}^0(\tau) = \frac{1}{N\beta} \int d\tau \sum_{k_1,k_2,k_3,k_4} c^\dagger(k_1) \frac{1}{2} \sigma^\alpha c(k_2) \cdot c^\dagger(k_3) \frac{1}{2} \sigma^\beta c(k_4) e^{i(\omega_1 - \omega_2 + \omega_3 - \omega_4)\tau} e^{i(k_1 - k_2) \cdot (i+4n)a\hat{x}} e^{i(k_1 - k_4) \cdot (j+4n)a\hat{x}},$$  \hspace{1cm} (D1)

in which $k = (i\omega, \vec{k})$ where $\omega$ is Matsubara frequency and $\vec{k}$ is the wavevector in space (we define the spatial wavevector as a vector to distinguish it from the spacetime combined index $k$, even though the system is 1D and $\vec{k}$ is in essence a scalar), $a$ is the lattice spacing, $N$ is the system size, $\beta$ is the inverse of the temperature, $n$ is summed over the unit cells, and $\hat{x}$ is the unit vector in the spatial direction. Using the identity

$$\frac{1}{N} \sum_n e^{i(\vec{k}_1 - \vec{k}_2 + \vec{k}_3 - \vec{k}_4) \cdot 4n a\hat{x}} = \frac{1}{4} \sum_{m=1} \delta_{\vec{k}_1 - \vec{k}_2 + \vec{k}_3 - \vec{k}_4, \frac{\pi}{2a} m\hat{x}},$$  \hspace{1cm} (D2)

Eq. (D1) can be written as

$$\frac{\Delta}{N\beta} \frac{1}{4} \sum_{m} \sum_{k_1,k_2,k_3,k_4} e^{i(\vec{k}_1 - \vec{k}_2) \cdot (i-j)a\hat{x}} e^{-i\frac{\pi}{2a} m\hat{x}} \delta_{k_1-k_2+k_3-k_4, \frac{\pi}{2a} m\hat{x}} c^\dagger(k_1) \frac{1}{2} \sigma^\alpha c(k_2) \cdot c^\dagger(k_3) \frac{1}{2} \sigma^\beta c(k_4),$$  \hspace{1cm} (D3)

i.e.,

$$\frac{\Delta}{N\beta} \frac{1}{4} \sum_{m} \sum_{k,k'q} e^{i\vec{q} \cdot (i-j)a\hat{x}} e^{-i\frac{\pi}{2a} m\hat{x}} c^\dagger(k+q) \frac{1}{2} \sigma^\alpha c(k) \cdot c^\dagger(k'-q) \frac{1}{2} \sigma^\beta c(k' + \frac{\pi}{2a} m\hat{x}),$$  \hspace{1cm} (D4)

where

$$c^\dagger(k) = \frac{1}{\sqrt{N\beta}} \int d\tau \sum_{j=1}^N e^{i\tau} e^{i(\omega\tau - \vec{k} \cdot j a\hat{x})}.$$  \hspace{1cm} (D5)
By defining the Fourier transform $h_\alpha^q(q)$ as

$$h_\alpha^q(q) = \frac{1}{\sqrt{N\beta}} \int d\tau \sum_{n=1}^{N/4} h_\alpha^q(\tau, n) e^{i(\omega \tau - q 4n a \hat{x})}, \tag{D6}$$

the coupling to the magnetic field becomes

$$\int d\tau \sum_n h_\alpha^q(\tau, n) S_{\alpha i+4n}^\alpha(\tau) = \frac{1}{4} \sum_{kq} e^{i\bar{q} \cdot \bar{a} \bar{a}} e^{i\bar{z} m l} h_\alpha^\nu(-q) c^\dagger(k + \frac{\pi}{2a} m \hat{x}) \frac{1}{2} \sigma^\nu c(k - q). \tag{D7}$$

Notice that $\bar{q} \in [0, \frac{\pi}{2a})$ in $h_\alpha^q(q)$ since $h_\alpha^q(n)$ is defined every four sites.

We set the momentum transfer $q'$ in $h_\alpha^q(q')$ as $|q'| \sim 0$ (both $S_\alpha^\nu$ and $S_\alpha^\alpha$ correspond to $|q'| \sim 0$, which is the reason why they are not separated above the energy scale $\Lambda_s$). The expression corresponding to the diagram in Fig. 5 is given by

$$\frac{1}{4N\beta} \sum_m e^{-i\bar{z} m} \sum_{kpq} e^{i\bar{q} (i-j) \bar{a} \bar{a}} c^\dagger(k + q + \frac{\pi}{2a} \bar{m} \hat{x}) \frac{1}{2} \sigma^\nu c(k) e^{-i\bar{q} (i-j) \bar{a} \bar{a}} \times \langle c^\dagger(p - q) \frac{1}{2} \sigma^\nu c(p + \frac{\pi}{2a} m \hat{x}) c^\dagger(k' + \frac{\pi}{2a} m' \hat{x}) \frac{1}{2} \sigma^\alpha c(k' - q') \rangle_l. \tag{D8}$$

Since the free fermion propagator is diagonal in the frequency-momentum space, there are the following constraints ($\bar{m} = 1, 2, 3, 4$)

$$m' = m + \bar{m}, \quad p = k' + \frac{\pi}{2a} \bar{m}, \quad q = q' + \frac{\pi}{2a} \bar{m}. \tag{D9}$$

Plugging Eq. (D9) into Eq. (D8) and rearranging the terms, we obtain the following alternative expression for Eq. (D8),

$$\frac{1}{4} \sum_m e^{i\bar{z} m} \sum_{kpq} e^{i\bar{q} (i-j) \bar{a} \bar{a}} h_\alpha^\nu(-q') c^\dagger(k + q' + \frac{\pi}{2a} \bar{m} \hat{x}) \frac{1}{2} \sigma^\nu c(k) e^{-i\bar{q} (i-j) \bar{a} \bar{a}} \times \frac{1}{4N\beta} \sum_m \sum_k e^{-i\bar{z} (m+\bar{m}) (i-j) \bar{a} \bar{a}} \langle c^\dagger(k' - q') \frac{1}{2} \sigma^\nu c(k' + \frac{\pi}{2a} (m + \bar{m}) \hat{x}) c^\dagger(k' + \frac{\pi}{2a} (m + \bar{m}) \hat{x}) \frac{1}{2} \sigma^\alpha c(k' - q') \rangle_l. \tag{D10}$$

In Eq. (D10), the factor $e^{-i\bar{q} (i-j) \bar{a} \bar{a}}$ can be set as 1 since $\bar{q}'$ is a slowly varying variable. In fact, if we expand the exponential $e^{-i\bar{q} (i-j) \bar{a} \bar{a}}$, $|\bar{q}'|^n$ becomes gradients in the real space, which renders the $n \neq 0$ terms less relevant than the leading $n = 0$ term in the RG sense. This justifies in a more rigorous way why $e^{-i\bar{q} (i-j) \bar{a} \bar{a}}$ can be taken as 1.

Then by using Eq. (D7), it can be checked that Eq. (D10) becomes

$$\lambda_{jl} \delta_{\nu\alpha} \Delta \ln b \cdot \int d\tau \sum_n h_\alpha^\nu(\tau, n) S^\alpha_{\nu j}(\tau, n), \tag{D11}$$

in which

$$\lambda_{jl} \Delta \ln b = -\frac{\alpha}{8} \sum_m e^{-i\bar{z} m (i-j)} \int_{\Lambda/b}^\Lambda d^2 k G(k) G(k + \frac{\pi}{2a} m \hat{x}), \tag{D12}$$

where $G(k)$ is the free fermion Green’s function defined as

$$G(k) = \frac{1}{i\omega - \epsilon(k)}. \tag{D13}$$

In Eq. (D13), $\epsilon(k)$ is the free fermion dispersion which includes the chemical potential term.
The expression corresponding to Fig. 6 is

$$
\frac{1}{16\pi^2} \sum_{kq} \sum_m \sum_{k'q'} e^{-i\vec{q} \cdot \vec{m}} e^{i\vec{q} \cdot \vec{m}' + i\vec{q} \cdot \vec{m}'' + i\vec{q} \cdot \vec{m}'''} e^{i\vec{q} \cdot \vec{m}'''} h^{a'}_{a''} (-q') c^l (k' + \frac{\pi}{2} m') \frac{1}{2} \sigma^\alpha c (k' - q') c^l (p - q - \frac{\pi}{2} m) \frac{1}{2} \sigma^\nu c (p).
$$

(D14)

Momentum conservation requires

$$
k = k' + \frac{\pi}{2a} (m + \tilde{m}),
$$

$$
q = p - k' + q' - \frac{\pi}{2a} m,
$$

$$
m' = m + \tilde{m}.
$$

(D15)

Then it can be shown that Eq. (D14) becomes

$$
\frac{1}{16\pi^2} \sum_{kq} \sum_m e^{i\vec{q} \cdot \vec{m}} e^{i\vec{q} \cdot \vec{m}' + i\vec{q} \cdot \vec{m}''} e^{i\vec{q} \cdot \vec{m}'''} h^{a'}_{a''} (-q') c^l (p + q' + \frac{\pi}{2a} \tilde{m}) \frac{1}{2} \sigma^\alpha \sigma^\nu c (p)
$$

$$
\times \frac{1}{4} \sum_{k'} \sum_{m} e^{i\vec{q}' \cdot \vec{m}} e^{i\vec{q}' \cdot \vec{m}'} e^{i\vec{q}' \cdot \vec{m}''} h^{a}_{a'} (m + \tilde{m}) (l - i) \frac{1}{2} \sigma^\nu \sigma^\alpha \bar{c} (p') G (k' + \frac{\pi}{2a} (m + \tilde{m}) \hat{x}) G (k' - q'),
$$

(D16)

in which the factor of two before the Green’s function comes from the sum over the spin degree of freedom, and $\sum_{k'}$ is restricted within the momentum shell, i.e., the last modes. Notice that

$$
\int d\tau \sum_n c^l_{i+4n} \frac{1}{2} \sigma^\nu c_{j+4n} h^{a}_{a'} (n) = \frac{1}{4\pi^2} \sum_{pq} \sum_m e^{i\vec{q} \cdot \vec{m}} e^{i\vec{q} \cdot \vec{m}' + i\vec{q} \cdot \vec{m}''} e^{i\vec{q} \cdot \vec{m}'''} h^{a'}_{a''} (-q') c^l (p + q' + \frac{\pi}{2a} \tilde{m}) \frac{1}{2} \sigma^\nu \sigma^\alpha c (p).
$$

(D17)

Plugging Eq. (D17) into Eq. (D16) and neglecting the $e^{i\vec{q}' \cdot \vec{m}'} (l) \hat{x}$ factor in Eq. (D16) since $q'$ is a very small wavevector, we obtain

$$
\lambda_{ij} \Delta \ln b \int d\tau \sum_n h^{l \mu \nu}_{l'} s^{\mu \nu}_{i+4n} (\tau),
$$

(D18)

where the coefficient $\lambda_{ij}$ is

$$
\lambda_{ij} \Delta \ln b = a \sum_m e^{i\vec{q} \cdot \vec{m} (l - i)} \int_{\Lambda/b} d^2 k' e^{i\vec{k}' \cdot \vec{m}} e^{i\vec{k}' \cdot \vec{m}'} e^{i\vec{k}' \cdot \vec{m}''} G (k' + \frac{\pi}{2a} \tilde{m} \hat{x}).
$$

(D19)

Notice that shifting $l$ by a multiple of 4 does not affect the result in Eq. (D19), hence we can impose the condition $l \geq \min \{i, j\}$. Apparently, Eq. (D19) is invariant under spatial translation $(i, j, l \rightarrow i + t, j + t, l + t)$ and inversion $(i, j, l \rightarrow -i, -j, -l)$, as it must be.

Appendix E: Explicit RG flow equations

The explicit flow equations for $h^{\mu}_{i} (1 \leq l \leq 4$ and $\mu = x, y, z$) are

$$
\frac{dh^{l}_{i}}{d\ln b} = h^{l}_{i} - (K + 2J) \sum_j \lambda_{2j} h^{l}_{j} + \Gamma \sum_j \lambda_{4j} h^{l}_{j},
$$

$$
\frac{dh^{l}_{j}}{d\ln b} = h^{l}_{j} - (K + 2J) \sum_j \lambda_{4j} h^{l}_{j} - \Gamma \sum_j \lambda_{2j} h^{l}_{j},
$$

$$
\frac{dh^{l}_{j}}{d\ln b} = h^{l}_{j} + \Gamma \sum_j \lambda_{4j} h^{l}_{j} - \Gamma \sum_j \lambda_{2j} h^{l}_{j},
$$

$$
\frac{dh^{l}_{i}}{d\ln b} = h^{l}_{i} - (K + 2J) \sum_j \lambda_{1j} h^{l}_{j} - \Gamma \sum_j \lambda_{3j} h^{l}_{j},
$$

$$
\frac{dh^{l}_{j}}{d\ln b} = h^{l}_{j} - (K + 2J) \sum_j \lambda_{3j} h^{l}_{j} - \Gamma \sum_j \lambda_{1j} h^{l}_{j},
$$

$$
\frac{dh^{l}_{z}}{d\ln b} = h^{l}_{z} - \Gamma \sum_j \lambda_{3j} h^{l}_{j} - \Gamma \sum_j \lambda_{1j} h^{l}_{j},
$$

(E1)

(E2)
\[
\frac{dh_3^x}{d\ln b} = h_3^x - (K + 2J) \sum_j \lambda_{ij}h_j^z - \Gamma \sum_j \lambda_{2j}h_j^z,
\]
\[
\frac{dh_3^y}{d\ln b} = h_3^y - (K + 2J) \sum_j \lambda_{ij}h_j^x + \Gamma \sum_j \lambda_{2j}h_j^x,
\]
\[
\frac{dh_3^z}{d\ln b} = h_3^z - \Gamma \sum_j \lambda_{ij}h_j^x + \Gamma \sum_j \lambda_{2j}h_j^x,
\]
(E3)

\[
\frac{dh_4^x}{d\ln b} = h_4^x - (K + 2J) \sum_j \lambda_{3j}h_j^z + \Gamma \sum_j \lambda_{1j}h_j^z,
\]
\[
\frac{dh_4^y}{d\ln b} = h_4^y - (K + 2J) \sum_j \lambda_{1j}h_j^y + \Gamma \sum_j \lambda_{3j}h_j^y,
\]
\[
\frac{dh_4^z}{d\ln b} = h_4^z + \Gamma \sum_j \lambda_{1j}h_j^x + \Gamma \sum_j \lambda_{3j}h_j^y,
\]
(E4)
in which \(\lambda_{41}\) and \(\lambda_{14}\) should be understood as \(\lambda_{45}\) and \(\lambda_{54}\), respectively.

**Appendix F: Invariance of RG flow equations under symmetries**

Apparently, Eqs. (38) does not respect the U(1) symmetry. We will verify that they are invariant under the nonsymmetric symmetries in Eq. (4).

1) Eq. (38) remains invariant under \(h_l^\mu \to -h_l^\mu\), hence time reversal symmetry is satisfied.

2) Suppose we shift \(l\) to \(l + 1\), and perform the rotation on spin indices by \(R_z = R(\hat{z}, -\frac{\pi}{2})\), then Eq. (38) becomes

\[
\frac{dh_{l+1}^{R_{\mu}}}{d\ln b} = h_{l+1}^{R_{\mu}} - \sum_{\gamma,k} (K + 2J) [\delta_{l+1,i}^{R_{\mu},\gamma} \lambda_{jk}^{\gamma} + \delta_{l+1,j}^{R_{\mu},\gamma} \lambda_{ik}^{\gamma}] - \sum_{\gamma,k} \epsilon(\gamma) [\delta_{l+1,i}^{R_{\mu},\alpha} \lambda_{jk}^{\alpha} + \delta_{l+1,j}^{R_{\mu},\alpha} \lambda_{ik}^{\alpha}] + \delta_{l+1,j}^{R_{\mu}, \alpha} \lambda_{ik}^{\alpha}.
\]
(F1)

Define \(R_z'\) as \(R_z'(x,y,\bar{x},\bar{y}) = (y,\bar{x},\bar{y},x)\). Then \(i + 1, j + 1 > R_z'\gamma\). Notice that \(R_z\alpha \neq R_z\beta \neq R_z\gamma\) if \(\alpha \neq \beta \neq \gamma\), and \(\epsilon(R_z'\gamma) = (-1)^{i+1}\epsilon(\gamma)\) where \(\gamma = < i, j >\). Then we can change the dummy variable from \(\gamma\) to \(R_z'\gamma\) and also from \(k\) to \(k + 1\). As a result, Eq. (F1) becomes

\[
\frac{dh_{l+1}^{R_{\mu}}}{d\ln b} = h_{l+1}^{R_{\mu}} - \sum_{\gamma,k} (K + 2J) [\delta_{l+1,i+1}^{R_{\mu},\gamma} \lambda_{j+1,k+1}^{R_z\gamma} + \delta_{l+1,j+1}^{R_{\mu},\gamma} \lambda_{i+1,k+1}^{R_z\gamma}] - \sum_{\gamma,k} \epsilon(\gamma) [\delta_{l+1,i+1}^{R_{\mu},\alpha} \lambda_{j+1,k+1}^{R_z\alpha} + \delta_{l+1,j+1}^{R_{\mu},\alpha} \lambda_{i+1,k+1}^{R_z\alpha}] + \delta_{l+1,j+1}^{R_{\mu}, \alpha} \lambda_{i+1,k+1}^{R_z\alpha},
\]
(F2)
in which \(i, j, \alpha, \beta\) have been changed to \(i + 1, j + 1, R_z\alpha, R_z\beta\), respectively, in accordance with changing \(\gamma\) to \(R_z\gamma\). Using \(\lambda_{jk} = \lambda_{j+1,k+1}\) and \(\delta_{l\gamma} = \delta_{R_{\mu},R_z\gamma}\), we obtain

\[
\frac{dh_{l+1}^{R_{\mu}}}{d\ln b} = h_{l+1}^{R_{\mu}} - \sum_{\gamma,k} (K + 2J) [\delta_{l,i}^{R_{\mu},\gamma} \lambda_{jk}^{R_z\gamma} + \delta_{l,j}^{R_{\mu},\gamma} \lambda_{ik}^{R_z\gamma}] - \sum_{\gamma,k} \epsilon(\gamma) [\delta_{l,i}^{R_{\mu},\alpha} \lambda_{jk}^{R_z\alpha} + \delta_{l,j}^{R_{\mu},\alpha} \lambda_{ik}^{R_z\alpha}] + \delta_{l,j}^{R_{\mu}, \alpha} \lambda_{ik}^{R_z\alpha},
\]
(F3)

Using the fact that the site index \(i\) in Eq. (F5) is the left point of the bond \(\gamma\), we see that

\[
(-1)^{i+1} = (-1)^{\delta_{\alpha,z} + \delta_{\beta,z}}.
\]
(F4)
Hence, we note that the sign factor \((-)^{i-1}\) in the second term in the right hand side of Eq. (F5) can be replaced by either \((-)^{\delta_{\nu},\alpha + \delta_{\nu},x}\) (for the $R_{k+1}^{\alpha \beta}$ term), or \((-)^{\delta_{\nu},\alpha + \delta_{\nu},x}\) (for the $R_{k+1}^{R_{\alpha \beta}}$ term), since in whichever case the sign factor is \((-)^{\delta_{\nu},\alpha + \delta_{\nu},x}\) because of the Kronecker delta $\delta_{\mu \alpha}$ (for the $R_{k+1}^{R_{\alpha \beta}}$ term), and $\delta_{\mu \beta}$ (for the $R_{k+1}^{R_{\alpha \beta}}$ term). Therefore, Eq. (F5) can be re-written as

$$\frac{d h_{R_{k+1}^{R_{\mu \gamma}}}}{d \ln b} = h_{R_{k+1}^{R_{\mu \gamma}}} - \sum_{\gamma, k} (K + 2J) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right]$$

$$- \sum_{\gamma, k} \epsilon(\gamma) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right]$$

$$\left. + \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right].$$  \hspace{1cm} (F5)

On the other hand, using $R_{y}(S^x, S^y, S^z) \rightarrow (-S^y, S^x, S^z)$, it can be seen that the invariance of the RG flow equations under the symmetry operation $R_y T_a$ exactly requires Eq. (F5). Hence we conclude that the flow equations have the symmetry imposed by $R_y T_a$.

3) Suppose we perform an operation on $h_{y \gamma}^\alpha$ (1 \leq i \leq 4, \alpha = x, y, z) as

$$h_{y \gamma}^\alpha \rightarrow h_{y \gamma}^{R_{\mu \gamma}},$$  \hspace{1cm} (F6)

in which $R_y$ is $R(\hat{\gamma}, \pi)$ for short. Then Eq. (F8) becomes

$$\frac{d h_{R_{y \gamma}^{R_{\mu \gamma}}}}{d \ln b} = h_{R_{y \gamma}^{R_{\mu \gamma}}} - \sum_{\gamma, k} (K + 2J) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$- \sum_{\gamma, k} \epsilon(\gamma) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$\left. + \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right].$$  \hspace{1cm} (F7)

Define $R_y(x, y, z) = (\bar{x}, y, \bar{y})$. Then \(5 - i, 5 - j) = R_y \gamma). Notice that $R_y \alpha \neq R_y \beta \neq R_y \gamma$ if $\alpha \neq \beta \neq \gamma$, and $\epsilon(R_y \gamma) = (-)^{i} \epsilon(\gamma)$ where $\gamma < i, j >$. Then we can change the dummy variable from $\gamma$ to $R_y \gamma$ and also from $k$ to $5 - k$. As a result, Eq. (F7) becomes

$$\frac{d h_{R_{y \gamma}^{R_{\mu \gamma}}}}{d \ln b} = h_{R_{y \gamma}^{R_{\mu \gamma}}} - \sum_{\gamma, k} (K + 2J) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$- \sum_{\gamma, k} \epsilon(\gamma) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$\left. + \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right].$$  \hspace{1cm} (F8)

In which, $i, j, \alpha, \beta$ have been changed to $5 - j, 5 - i, R_y \alpha, R_y \beta$, respectively, in accordance with changing $\gamma$ to $R_y \gamma$. Using $\lambda_{jk} = \lambda_{5-5, \gamma}$ and $\delta_{\mu \gamma} = \delta_{R_y \mu, R_y \gamma}$, we obtain

$$\frac{d h_{R_{y \gamma}^{R_{\mu \gamma}}}}{d \ln b} = h_{R_{y \gamma}^{R_{\mu \gamma}}} - \sum_{\gamma, k} (K + 2J) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$- \sum_{\gamma, k} \epsilon(\gamma) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right]$$

$$\left. + \delta_{\mu \nu, \gamma} \lambda_{jk} R_{y \gamma}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{y \gamma}^{R_{\gamma \nu}} \right].$$  \hspace{1cm} (F9)

Using the fact that the site index $i$ in Eq. (F5) is the left point of the bond $\gamma$, we see that

$$(-)^i = (-)^{\delta_{\nu},x + \delta_{\nu},x + \delta_{\nu},x + \delta_{\nu},x}.$$  \hspace{1cm} (F10)

Hence, we note that the sign factor \((-)^i\) in the second term in the right hand side of Eq. (F8) can be replaced by either \((-)^{\delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha}}\) (for the $R_{k+1}^{R_{\mu \gamma}}$ term), or \((-)^{\delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha}}\) (for the $R_{k+1}^{R_{\mu \gamma}}$ term), since in whichever case the sign factor is \((-)^{\delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha} + \delta_{\nu,\alpha}}\) because of the Kronecker delta $\delta_{\mu \alpha}$ (for the $R_{k+1}^{R_{\mu \gamma}}$ term), and $\delta_{\mu \beta}$ (for the $R_{k+1}^{R_{\mu \gamma}}$ term).

On the other hand, using $R_{y}(S^x, S^y, S^z) \rightarrow (-S^y, S^x, -S^z)$, it can be seen that the invariance of the RG flow equations under the symmetry operation $R_y I$ exactly requires Eq. (F9). Hence we conclude that the flow equations have the symmetry imposed by $R_y I$. 

$$\frac{d h_{R_{k+1}^{R_{\mu \gamma}}}}{d \ln b} = h_{R_{k+1}^{R_{\mu \gamma}}} - \sum_{\gamma, k} (K + 2J) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right]$$

$$- \sum_{\gamma, k} \epsilon(\gamma) \left[ \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right]$$

$$\left. + \delta_{\mu \nu, \gamma} \lambda_{jk} R_{k+1}^{R_{\gamma \nu}} + \delta_{\mu \nu, \gamma} \lambda_{ik} R_{k+1}^{R_{\gamma \nu}} \right].$$  \hspace{1cm} (F10)
Appendix G: Numerical determination for the signs of the “D” coefficients

In this appendix, we study the signs of the five “D” coefficients. As in Sec. [V D], we work in the four-sublattice rotated frame and take the parameters as \( K + 2J = 1, J = -1, \Gamma = 0.35 \). DMRG numerical simulations are performed on a system of \( L = 144 \) sites with periodic boundary conditions. The bond dimension \( m \) and truncation error \( \epsilon \) in DMRG simulations are taken as \( m = 1400 \) and \( \epsilon = 10^{-9} \).

We add a small uniform magnetic field along the \( z \)-direction as

\[
-h_0 \sum_n (S^x_{1+4n} + S^y_{2+4n} + S^z_{3+4n} + S^z_{4+4n}).
\]

The low energy Hamiltonian can be derived as \(-h_0^2 \epsilon_D \int dx J^z\). Using the nonsymmorphic bosonization formulas, the spin expectation values are expected to be

\[
\langle \vec{S}_{1+4n} \rangle = \langle J^z \rangle (h_D, -h_D, i_D),
\]

\[
\langle \vec{S}_{2+4n} \rangle = \langle J^z \rangle (-h_D, -h_D, i_D),
\]

\[
\langle \vec{S}_{3+4n} \rangle = \langle J^z \rangle (-h_D, h_D, i_D),
\]

\[
\langle \vec{S}_{4+4n} \rangle = \langle J^z \rangle (h_D, h_D, i_D).
\]

Choosing \( h_0 = 10^{-3} \), DMRG numerical simulations give

\[
S^x \simeq -1.004 \times 10^{-6} \times (+, -, - ,+)
\]

\[
S^y \simeq -1.004 \times 10^{-6} \times (-, - , + ,+)
\]

\[
S^z \simeq 5.25 \times 10^{-7} \times (+, +, +, +).
\]

Comparing with Eq. (G2), we obtain

\[
\langle J^z \rangle h_D = -1.004 \times 10^{-6},
\]

\[
\langle J^z \rangle i_D = 5.25 \times 10^{-7}.
\]

If we add the following mixture of the magnetic fields in the \( xy \)-plane,

\[
-h_x^y \sum_n (S^y_{1+4n} + S^y_{2+4n} + S^y_{3+4n} + S^y_{4+4n}) + b_c \sum_n (-S^x_{1+4n} + S^x_{2+4n} - S^x_{3+4n} + S^x_{4+4n}).
\]

then the low energy Hamiltonian is

\[
-h_x^y (a_c a_D - b_c b_D) \int dx J^y.
\]

Using the nonsymorphic bosonization formulas, the spin expectation values are expected to be

\[
\langle \vec{S}_{1+4n} \rangle = \langle J^y \rangle (b_D, a_D, -c_D),
\]

\[
\langle \vec{S}_{2+4n} \rangle = \langle J^y \rangle (-b_D, a_D, -c_D),
\]

\[
\langle \vec{S}_{3+4n} \rangle = \langle J^y \rangle (b_D, a_D, c_D),
\]

\[
\langle \vec{S}_{4+4n} \rangle = \langle J^y \rangle (-b_D, a_D, c_D).
\]

Choosing \( h_x^y = 10^{-3} \), DMRG numerical simulations give

\[
S^x \simeq -9.53 \times 10^{-5} \times (+, -, +, -)
\]

\[
S^y \simeq 1.30 \times 10^{-6} \times (+, +, +, +)
\]

\[
S^z \simeq -4.13 \times 10^{-6} \times (-, -, +, +).
\]

From Eq. (G6) and Eq. (G12), the ratios can be determined as

\[
h_D/i_D = -1.91,
\]

\[
b_D/a_D = -73.3,
\]

\[
c_D/a_D = -3.18.
\]
predictions), the absolute values of the ratios in Eq. (G13) severely violate the relations in Eq. (65). The huge discrepancies in the “D” coefficients when magnetic field responses are studied remain puzzling, and the reasons are unclear.
