Nearly convex sets: fine properties and domains or ranges of subdifferentials of convex functions

Sarah M. Moffat, Walaa M. Moursi, and Xianfu Wang

Dedicated to R.T. Rockafellar on the occasion of his 80th birthday.

July 28, 2015

Abstract

Nearly convex sets play important roles in convex analysis, optimization and theory of monotone operators. We give a systematic study of nearly convex sets, and construct examples of subdifferentials of lower semicontinuous convex functions whose domain or ranges are nonconvex.

2000 Mathematics Subject Classification: Primary 52A41, 26A51, 47H05; Secondary 47H04, 52A30, 52A25.

Keywords: Maximally monotone operator, nearly convex set, nearly equal, relative interior, recession cone, subdifferential with nonconvex domain or range.

1 Introduction

In 1960s Minty and Rockafellar coined nearly convex sets \[22, 25\]. Being a generalization of convex sets, the notion of near convexity or almost convexity has been gaining popu-

larity in the optimization community, see [6, 11, 12, 13, 16]. This can be attributed to the applications of generalized convexity in economics problems, see for example, [19, 21]. One reason to study nearly convex sets is that for a proper lower semicontinuous convex function its subdifferential domain is always nearly convex [24, Theorem 23.4, Theorem 6.1], and the same is true for the domain of each maximally monotone operator [26, Theorem 12.41]. Maximally monotone operators are extensively studies recently [1, 2, 3, 4, 27]. Another reason is that to study possibly nonconvex functions, a first endeavor perhaps should be to study functions whose epigraphs are nearly convex, see, e.g., [13].

All these motivate our systematic study of nearly convex sets. Some properties of nearly convex sets have been partially studied in [6, 11, 12, 13] from different perspectives. The purpose of this paper is to give new proofs to some known results, provide further characterizations, and extend known results on calculus, relative interiors, recession cones, and applications. Although nearly convex sets need not be convex, many results on convex sets do extend. We also construct proper lower semicontinuous convex functions whose subdifferential mappings have domains being neither closed nor open; or highly nonconvex.

We remark that nearly convex was called *almost convex* in [11, 12, 13]. Here, we adopt the term *nearly convex* rather than *almost convex* because of the relationship with nearly equal sets which was noted in [6]. Note that this definition of nearly convex does not coincide with the one provided in [11, Definition 2] and [12], where nearly convex is a generalization of midpoint convexity.

The remainder of the paper is organized as follows. Some basic notations and facts about convex sets and nearly convex sets are given in Section 2. Section 3 gives new characterizations of nearly convex sets. In Section 4 we give calculus of nearly convex sets and relative interiors. In Section 5 we study recessions of nearly convex sets. Section 6 is devoted to apply results in Section 4 and Section 5 to study maximality of sum of several maximally monotone operators and closedness of nearly convex sets under a linear mapping. In Section 7 we construct examples of proper lower semicontinuous convex functions with prescribed nearly convex sets being their subdifferential domain. As early as 1970s, Rockafellar provided a convex function whose subdifferential domain is not convex [24]. We give a detailed analysis of his classical example and use it to generate new examples with pathological subdifferential domains. Open problems appear in Section 8. Appendix A contains some proofs of Section 7.
2 Preliminaries

2.1 Notation and terminology

Throughout this paper, we work in the Euclidean space $\mathbb{R}^n$ with norm $\| \cdot \|$ and inner product $\langle \cdot, \cdot \rangle$. For a set $C \subseteq \mathbb{R}^n$ let $\text{cl} C$ denote the closure of $C$, and $\text{aff} C$ the affine hull of $C$; that is, the smallest affine set containing $C$. The key object we shall study is:

**Definition 2.1 (near convexity)** A set $E \subseteq \mathbb{R}^n$ is nearly convex if there exists a convex set $C \subseteq \mathbb{R}^n$ such that $C \subseteq E \subseteq \text{cl} C$.

Obviously, every convex set is nearly convex, but there are many nearly convex sets which are not convex. See Figure 1 for two nearly convex sets.

![Figure 1: A GeoGebra snapshot. Left: Neither open nor closed convex set. Right: Nearly convex but not convex set](image)

Note that nearly convex sets do not have nice algebra as convex sets do [24 Section 3], as the following two simple examples illustrate.

**Example 2.2** The nearly convex set $C \subseteq \mathbb{R}^2$ given by

$$C := \{(x_1, x_2) \mid -1 < x_1 < 1, x_2 > 0\} \cup \{(-1,0), (1,0)\}.$$ 

has $2C \neq C + C$, since

$$2C = \{(x_1, x_2) \mid -2 < x_1 < 2, x_2 > 0\} \cup \{(-2,0), (2,0)\},$$

$C + C = 2C \cup (0,0)$. 

On the contrary, $2C = C + C$ whenever $C$ is a convex set [24 Theorem 3.2].

**Example 2.3** Define

$$E_1 := \{ (x_1, x_2) \mid x_1 \geq 0, x_2 \in \mathbb{R} \} \setminus \{ (0, x_2) \mid |x_2| < 1 \},$$

$$E_2 := \{ (x_1, x_2) \mid x_1 \leq 0, x_2 \in \mathbb{R} \} \setminus \{ (0, x_2) \mid |x_2| < 1 \}.$$

The set $E_1 \cap E_2 = \{ (0, x_2) \mid |x_2| \geq 1 \}$ is not nearly convex. On the contrary, $E_1 \cap E_2$ is convex if both $E_1, E_2$ are convex.

Let $B(x, \varepsilon) \subset \mathbb{R}^n$ be the closed ball with radius $\varepsilon > 0$ and centered at $x$, and let $I$ be an index set $I := \{1, 2, \ldots, m\}$ for some integer $m$. We use $\text{conv } C$ for the convex hull of $C$. The interior of $C$ is $\text{int } C$, the core is

$$\text{core } C := \{ x \in C \mid (\forall y \in \mathbb{R}^n)(\exists \varepsilon > 0) [x - \varepsilon y, x + \varepsilon y] \subseteq C \},$$

and the relative interior is

$$\text{ri } C := \{ x \in \text{aff } C \mid \exists \varepsilon > 0, (x + \varepsilon B(0, 1)) \cap (\text{aff } C) \subseteq C \}.$$

The recession cone of $C$ is

$$\text{rec } C := \{ y \in \mathbb{R}^n \mid (\forall \lambda \geq 0) \lambda y + C \subseteq C \}. \quad (1)$$

The lineality space of $C$ is the largest subspace contained in $\text{rec } C$, see [24, page 65] for more on lineality spaces. We denote the projection operator onto the set $C \subseteq \mathbb{R}^n$ by $P_C$ and the normal cone operator by $N_C$.

For a set-valued mapping $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, the domain is $\text{dom } A := \{ x \in \mathbb{R}^n \mid Ax \neq \emptyset \}$, the range is $\text{ran } A := \bigcup_{x \in \mathbb{R}^n} Ax$, and the graph is $\text{gra } A := \{(x, u) \in \mathbb{R}^n \times \mathbb{R}^n \mid u \in Ax\}$. $A$ is monotone if $(\forall (x, u) \in \text{gra } A)(\forall (y, v) \in \text{gra } A) \quad \langle x - y, u - v \rangle \geq 0$, and maximally monotone if there exists no monotone operator $B$ such that $\text{gra } A$ is a proper subset of $\text{gra } B$.

### 2.2 Auxiliary results on convex sets

Properties of convex sets play a prominent role in the paper, we need to review some key results.

**Fact 2.4 (Rockafellar)** Let $C$ and $D$ be convex subsets of $\mathbb{R}^n$, and let $\lambda \in \mathbb{R}$. Then the following hold:
(i) $\text{ri } C$ and $\text{cl } C$ are convex.

(ii) $C \neq \emptyset \Rightarrow \text{ri } C \neq \emptyset$.

(iii) $\text{cl } (\text{ri } C) = \text{cl } C$.

(iv) $\text{ri } C = \text{ri } (\text{cl } C)$.

(v) $\text{aff}(\text{ri } C) = \text{aff } C = \text{aff } (\text{cl } C)$.

(vi) $\text{ri } C = \text{ri } D \iff \text{cl } C = \text{cl } D \iff \text{ri } C \subseteq D \subseteq \text{cl } C$.

(vii) $\text{ri } \lambda C = \lambda \text{ri } C$.

(viii) $\text{ri } (C + D) = \text{ri } C + \text{ri } D$.

Proof. (i)&(ii): See [24, Theorem 6.2]. (iii)&(iv): See [24, Theorem 6.3]. (v) See [24, Theorem 6.2]. (vi): See [24, Corollary 6.3.1]. (vii): See [24, Corollary 6.6.1]. (viii) See [24, Corollary 6.6.2]. ■

Fact 2.5 [24, Theorem 6.5] Let $C_i$ be a convex set in $\mathbb{R}^n$ for $i = 1, \ldots, m$ such that $\bigcap_{i=1}^{m} \text{ri } C_i \neq \emptyset$. Then

$$\text{cl } \left( \bigcap_{i=1}^{m} C_i \right) = \bigcap_{i=1}^{m} \text{cl } C_i,$$

and

$$\text{ri } \left( \bigcap_{i=1}^{m} C_i \right) = \bigcap_{i=1}^{m} \text{ri } C_i.$$

Fact 2.6 [24, Theorem 6.1] Let $C$ be a convex set in $\mathbb{R}^n$, $x \in \text{ri } C$, and $y \in \text{cl } C$. Then

$$[x, y] \subseteq \text{ri } C.$$

Fact 2.7 [24, Theorem 6.6] Let $C$ be a convex set in $\mathbb{R}^n$ and let $A$ be a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$. Then

$$\text{ri } (AC) = A(\text{ri } C),$$

and

$$A(\text{cl } C) \subseteq \text{cl } (AC).$$

Fact 2.8 [24, Theorem 6.7] Let $C$ be a convex set in $\mathbb{R}^n$ and let $A$ be a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$ such that $A^{-1}(\text{ri } C) \neq \emptyset$. Then

$$\text{ri } (A^{-1} C) = A^{-1}(\text{ri } C),$$

and

$$\text{cl } (A^{-1} C) = A^{-1}(\text{cl } C).$$
Fact 2.9 [24, Theorem 8.1 & Theorem 8.2] Let $C$ be a nonempty convex subset in $\mathbb{R}^n$. Then $\text{rec } C$ is a convex cone and $0 \in \text{rec } C$. If in addition $C$ is closed then $\text{rec } C$ is closed.

Fact 2.10 [24, Theorem 8.3] Let $C$ be a nonempty convex subset in $\mathbb{R}^n$. Then $\text{rec } (\text{ri } C) = \text{rec } (\text{cl } C)$.

Fact 2.11 [24, Theorem 9.1] Let $C$ be a nonempty convex subset in $\mathbb{R}^n$ and let $A$ be a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$. Suppose that $(\forall z \in \text{rec } (\text{cl } C) \setminus \{0\})$ with $Az = 0$ we have that $z$ belongs to the lineality space of $\text{cl } C$. Then

$$\text{cl } (AC) = A(\text{cl } C),$$
and

$$\text{rec } A(\text{cl } C) = A[\text{rec } (\text{cl } C)].$$

Fact 2.12 [24, Corollary 9.1.1] Let $(E_i)_{i \in I}$ be a family of nonempty convex subsets in $\mathbb{R}^n$ satisfying the following condition: if $(\forall i \in I)(\exists z_i \in \text{rec } (\text{cl } E_i))$ and $\sum_{i \in I} z_i = 0$ then $(\forall i \in I)z_i$ belongs to the lineality space of $\text{cl } E_i$. Then

$$\text{cl } (E_1 + \cdots + E_m) = \text{cl } E_1 + \cdots + \text{cl } E_m,$$

and

$$\text{rec } [\text{cl } (E_1 + \cdots + E_m)] = \text{rec } (\text{cl } E_1) + \cdots + \text{rec } (\text{cl } E_m).$$

2.3 Auxiliary results on nearly convex sets

Near equality introduced in [6] provides a convenient tool to study nearly convex sets and ranges of maximally monotone operators.

Definition 2.13 (near equality) Let $C$ and $D$ be subsets of $\mathbb{R}^n$. We say that $C$ and $D$ are nearly equal, if

$$\text{cl } C = \text{cl } D \text{ and } \text{ri } C = \text{ri } D.$$

and denote this by $C \approx D$.

Fact 2.14 [6, Lemma 2.7] Let $E$ be a nearly convex subset of $\mathbb{R}^n$, say $C \subseteq E \subseteq \text{cl } C$, where $C$ is a convex subset of $\mathbb{R}^n$. Then

$$E \approx \text{cl } E \approx \text{ri } E \approx \text{conv } E \approx \text{ri conv } E \approx C.$$

In particular, the following hold.

(i) $\text{cl } E$ and $\text{ri } E$ are convex.
(ii) If \(E \neq \emptyset\), then \(\text{ri} \, E \neq \emptyset\).

Fact 2.15 [6 Proposition 2.12(i),(ii),(iii)] Let \(E_1\) and \(E_2\) be nearly convex subsets of \(\mathbb{R}^n\). Then
\[
E_1 \approx E_2 \iff \text{ri} \, E_1 = \text{ri} \, E_2 \iff \text{cl} \, E_1 = \text{cl} \, E_2.
\] (6)

Fact 2.16 [6 Proposition 2.5] Let \(A, B\) and \(C\) be subsets of \(\mathbb{R}^n\) such that \(A \approx C\) and \(A \subseteq B \subseteq C\). Then \(A \approx B \approx C\).

Fact 2.17 (See [26 Theorem 12.41].) Let \(A : \mathbb{R}^n \rightharpoonup \mathbb{R}^n\) be maximally monotone. Then \(\text{dom} \, A\) and \(\text{ran} \, A\) are nearly convex.

Remark 2.18 Fact 2.17 can not be localized. Suppose that \(A := P_{B(0,1)}\) is the projection onto the unit ball in \(\mathbb{R}^2\), which is a gradient mapping of the continuous differentiable convex function \(f : \mathbb{R}^2 \to \mathbb{R}\) given by
\[
f(x) := \begin{cases} 
\|x\|^2/2 & \text{if } \|x\| \leq 1, \\
\|x\|-1/2 & \text{if } \|x\| > 1.
\end{cases}
\]

(i) Let \(S := \{(x,y) \in \mathbb{R}^2 \mid x + y > 2, x > 0, y > 0\}\) be open convex. The set \(\text{ran} \, P_{B(0,1)}(S) = \{(x,y) \in \mathbb{R}^2 \mid x^2 + y^2 = 1, x > 0, y > 0\}\) is not nearly convex.

(ii) Let \(S := \{(x,y) \in \mathbb{R}^2 \mid x + y \geq 2, x \geq 0, y \geq 0\}\) be closed convex. The set \(\text{ran} \, P_{B(0,1)}(S) = \{(x,y) \in \mathbb{R}^2 \mid x^2 + y^2 = 1, x \geq 0, y \geq 0\}\) is not nearly convex.

We refer readers to [9, 10, 4, 24, 27] for more materials on convex analysis and monotone operators.

3 Characterizations and basic properties of nearly convex sets

Utilizing near equality, in [6] the authors provide the following characterizations of nearly convex sets.

Fact 3.1 (characterization of near convexity) [6 Lemma 2.9] Let \(E \subseteq \mathbb{R}^n\). Then the following are equivalent:

(i) \(E\) is nearly convex.
(ii) $E \approx \text{conv } E$.

(iii) $E$ is nearly equal to a convex set.

(iv) $E$ is nearly equal to a nearly convex set.

(v) $\text{ri conv } E \subseteq E$.

We now provide further characterizations of nearly convex sets.

**Theorem 3.2** Let $E$ be a nonempty subset of $\mathbb{R}^n$. Then the following are equivalent:

(i) $E$ is nearly convex.

(ii) $\text{ri } E$ is convex and $\text{cl } (\text{ri } E) = \text{cl } E$.

(iii) $(\forall x \in \text{ri } E) (\forall y \in E) [x, y] \subseteq \text{ri } E$.

(iv) $\text{cl } E$ is convex and $\text{ri}(\text{cl } E) \subseteq \text{ri } E$.

**Proof.** (i)$\Rightarrow$(ii) This follows from Fact 2.14. (ii)$\Rightarrow$(i) We have $\text{ri } E \subseteq E \subseteq \overline{E} = \text{cl } (\text{ri } E)$. Since $\text{ri } E$ is convex, $E$ is nearly convex. (ii)$\Rightarrow$(iii) Since $E$ is nearly convex, by Fact 2.14 (i) $\text{cl } E$ is convex. Using Fact 2.6 applied to the convex set $\text{cl } E$ we conclude that $(\forall x \in \text{ri } E) (\forall y \in \text{cl } E) [x, y] \subseteq \text{ri } E = \text{ri } E$. In particular, $(\forall x \in \text{ri } E) (\forall y \in E) [x, y] \subseteq \text{ri } E$. (iii)$\Rightarrow$(ii) Let $x \in \text{ri } E$ and $y \in \text{ri } E$. Then $[x, y] = [x, y] \cup \{y\} \subseteq \text{ri } E \cup \text{ri } E = \text{ri } E$, that is $\text{ri } E$ is convex. It is obvious that $\text{cl } (\text{ri } E) \subseteq \text{cl } E$. Now we show that $\text{cl } E \subseteq \text{cl } (\text{ri } E)$. Indeed, let $y \in \text{cl } E$. Then $(\exists (y_n)_{n \in \mathbb{N}}) \subseteq E$ such that $y_n \to y$. Therefore $(\forall x \in \text{ri } E) [x, y_n] \subseteq \text{ri } E$, and consequently $[x, y] \subseteq \text{cl } E$. That is, $(y_n)_{n \in \mathbb{N}} \subseteq \text{cl } E$, hence $y \in \text{cl } (\text{ri } E)$, and therefore $\text{cl } E \subseteq \text{cl } (\text{ri } E)$, as claimed. (i)$\Rightarrow$(iv) This follows from Fact 2.14 (iv)$\Rightarrow$(i). Since $E$ is nonempty we have $\text{cl } E$ is nonempty and convex by assumption, hence $\text{cl } (\text{ri } E) = \text{cl } E$. Now $\text{ri}(\text{cl } E) \subseteq \text{ri } E \subseteq \text{cl } E = \text{cl } (\text{ri } E)$, hence $\text{ri}(\text{cl } E) \approx E$. Since $\text{cl } E$ is convex we have $\text{ri}(\text{cl } E)$ is convex. It follows from Fact 3.1 (iii) that $E$ is nearly convex. 

**Theorem 3.3** Let $E$ be a nonempty subset in $\mathbb{R}^n$. Then $E$ is nearly convex if and only if $E = C \cup S$ where $C$ is a nonempty convex subset of $\mathbb{R}^n$ and $S \subseteq \text{cl } C \setminus \text{ri } C$.

**Proof.** ($\Rightarrow$) Suppose that $E$ is nearly convex, and notice that $E = \text{ri } E \cup (E \setminus \text{ri } E)$. Set

$$
C := \text{ri } E \quad \text{and} \quad S := E \setminus \text{ri } E \subseteq \text{cl } E \setminus \text{ri } E.
$$

(7)

Since $E$ is nearly convex, it follows from Fact 2.14 that $C$ is nonempty and convex. Moreover $\text{cl } E = \text{cl } (\text{ri } E) = \text{cl } C$. Therefore $E = C \cup S$ with $C$ convex and $S \subseteq \text{cl } C \setminus \text{ri } C$. ($\Leftarrow$) Conversely, assume that $E = C \cup S$ where $C$ is a nonempty convex subset of $\mathbb{R}^n$ and
$S \subseteq \text{cl} C \setminus \text{ri} C$. Clearly, $S \subseteq \partial(\text{cl} C)$, where $\partial(\text{cl} C)$ is the relative boundary of $\text{cl} C$. Hence $\text{ri} E = \text{ri} C$ and consequently $\text{ri} E$ is nonempty and convex. Moreover, since $\text{cl} S \subseteq \text{cl} C$, we have $\text{cl} E = \text{cl}(C \cup S) = \text{cl} C \cup \text{cl} S = \text{cl} C$ and consequently $\text{cl} E$ is convex. Finally notice that

$$\text{ri} C = \text{ri} E \subseteq E \subseteq \text{cl} E = \text{cl} C = \text{cl}(\text{ri} C).$$

That is $E \approx \text{ri} C$ and hence $E$ is nearly convex by Fact 3.1(iii).

To study the relationship among core, interior and relative interior of a nearly convex set, we need two facts.

**Fact 3.4** Let $C$ be a convex set in $\mathbb{R}^n$. Then $\text{int} C = \text{core} C$. Moreover, if $\text{int} C \neq \emptyset$ then $\text{int} C = \text{ri} C$.

**Proof.** For the first part, see [8, Remark 2.73] or [4, Proposition 6.12]. The second part is clear from [24, pg 44].

**Fact 3.5** [6, Proposition 2.20] Let $E$ be a nearly convex subset of $\mathbb{R}^n$. Then $\text{int} E = \text{int}(\text{cl} E)$.

**Theorem 3.6** Let $E$ be a nonempty nearly convex subset in $\mathbb{R}^n$. Then the following hold:

(i) $\text{core} E = \text{int} E$.

(ii) If $\text{int} E \neq \emptyset$ then $\text{int} E = \text{ri} E$.

(iii) $\text{aff}(\text{ri} E) = \text{aff} E = \text{aff}(\text{cl} E)$.

**Proof.** (i) Since $E$ is nonempty and nearly convex, $\text{cl} E$ is nonempty and convex by Fact 2.14(i). Using Fact 3.5 and Fact 3.4 applied to the convex set $\text{cl} E$ we have

$$\text{int}(\text{cl} E) = \text{int} E \subseteq \text{core} E \subseteq \text{core}(\text{cl} E) = \text{int}(\text{cl} E).$$

Hence $\text{int} E = \text{core} E$, as claimed.

(ii) Notice that Fact 3.5 gives $\emptyset \neq \text{int} E = \text{int}(\text{cl} E)$. Moreover since $E$ is nearly convex, Fact 2.14 implies that $\text{ri} E = \text{ri}(\text{cl} E)$. Applying Fact 3.4 to the convex set $\text{cl} E$ gives

$$\text{int} E = \text{int}(\text{cl} E) = \text{ri}(\text{cl} E) = \text{ri} E.$$ (10)

(iii) It follows from Fact 2.14 that

$$\text{ri} E = \text{ri}(\text{ri} E) \quad \text{and} \quad \text{cl}(\text{ri} E) = \text{cl} E.$$ (11)
Using (11) and Fact 2.4(v) applied to the convex set $r_i E$ we have

$$\text{aff}(r_i E) = \text{aff}[\text{cl} (r_i E)] = \text{aff}(\text{cl} E).$$  \hspace{1cm} (12)

Under mild assumptions, a nearly convex set is in fact convex as our next result shows.

**Definition 3.7** We say that a set $E \subseteq X$ is relatively strictly convex if $[x, y] \subseteq r_i E$ whenever $x, y \in E$.

**Proposition 3.8** Let $E \subseteq \mathbb{R}^n$ be nearly convex. Then the following hold:

(i) If $E$ is relatively strictly convex, then $E$ is convex.

(ii) If $E$ is open, then $E$ is convex.

(iii) If $E$ is closed, then $E$ is convex.

(iv) If for every $x, y \in E \setminus r_i E$, we have $[x, y] \subseteq E$, then $E$ is convex.

**Proof.**

(i) Let $x, y \in E$. As $E$ is relatively strictly convex, $[x, y] \subseteq r_i E \subseteq E$, so $[x, y] \subseteq E$. Hence $E$ is convex.

(ii) For a nearly convex set $E$, we have $r_i E = r_i C$ where $C$ is a convex set. When $E$ is open and $\text{int} E \neq \emptyset$, by Theorem 3.6(ii) we have $E = r_i E = r_i C = \text{int} C$ is convex. Hence $E$ is convex.

(iii) Since there exists a convex set $C$ such that $C \subseteq E \subseteq \text{cl} C$ and $E$ closed, we have $E = \text{cl} C$, so $E$ is convex.

(iv) Let $x, y \in E$. If one of $x, y$ is in $r_i E$, then $[x, y] \subseteq E$; if both $x, y \in E \setminus r_i E$, then the assumption guarantees $[x, y] \subseteq E$. Hence $E$ is convex.

\section{4 Calculus and relative interiors of nearly convex sets}

In this section we extend the calculus for convex sets provided in [24, Section 6 and Section 8] to nearly convex sets. More precisely, we study the properties of images and pre-images of nearly convex sets under linear transforms. One distinguished feature is that when two nearly convex sets are nearly equal, their linear images or linear inverse images are also nearly equal. We start with
Proposition 4.1  

(i) Let \( E \subseteq \mathbb{R}^n \) be nearly convex, and \( \lambda \in \mathbb{R} \). Then \( \text{ri}(\lambda E) = \lambda \text{ri} E \).

(ii) If \((\forall i \in I) E_i \subseteq \mathbb{R}^n \) be nearly convex, then
\[
\text{ri}(E_1 \times \cdots \times E_m) = \text{ri} E_1 \times \cdots \times \text{ri} E_m,
\]
and
\[
\text{cl}(E_1 \times \cdots \times E_m) = \text{cl}(\text{ri} E_1) \times \cdots \times \text{cl}(\text{ri} E_m).
\]

Proof. (i) As \( E \) is nearly convex set, there exists a convex set \( C \subseteq \mathbb{R}^n \) such that \( \text{ri} E = \text{ri} C \). Then \( \text{ri}(\lambda E) = \text{ri}(\lambda C) = \lambda \text{ri} C = \lambda \text{ri} E \) by Fact 2.4(vii).

(ii) By Fact 2.14, we have
\[
\text{ri}(E_1 \times \cdots \times E_m) = \text{ri}[\text{cl}(E_1 \times \cdots \times E_m)] = \text{ri}(\text{cl} E_1 \times \cdots \times \text{cl} E_m)
\]
\[= \text{ri}(\text{cl} E_1) \times \cdots \times \text{ri}(\text{cl} E_m) = E_1 \times \cdots \times \text{ri} E_m.
\]
Also by Fact 2.14, \( \text{cl}(E_1 \times \cdots \times E_m) = \text{cl} E_1 \times \cdots \times \text{cl} E_m = \text{cl}(\text{ri} E_1) \times \cdots \times \text{cl}(\text{ri} E_m) \).

Theorem 4.2 Let \( E \) be a nearly convex set in \( \mathbb{R}^n \) and let \( A : \mathbb{R}^n \to \mathbb{R}^m \) be a linear transformation. Then the following hold:

(i) \( A(E) \) is nearly convex.

(ii) \( AE \approx A(\text{ri} E) \approx A(\text{cl} E) \).

(iii) \( \text{ri}(AE) = A \text{ri} E \).

Proof. (i) Since \( E \) is nearly convex we have \( \text{ri} E \) is convex. It follows from Fact 2.14 that \( \text{cl} E = \text{cl} \text{ri} E \). Moreover Fact 2.7 applied to the convex set \( \text{ri} E \) implies that \( A(\text{cl}(\text{ri} E)) \subseteq \text{cl} A(\text{ri} E) \). Therefore,
\[
A(\text{ri} E) \subseteq A(E) \subseteq A(\text{cl} E) = A(\text{cl}(\text{ri} E)) \subseteq \text{cl} A(\text{ri} E).
\]
Since \( A \) is linear and \( \text{ri} E \) is convex, we conclude that \( A(\text{ri} E) \) is convex, hence by (13) \( A(E) \) is nearly convex.

(ii) It follows from Fact 2.14 (13) and the fact that \( A(\text{ri} E) \) is convex that
\[
AE \approx A(\text{ri} E).
\]
To show \( A(\text{ri} E) \approx A(\text{cl} E) \), applying (14) to the convex set \( \text{cl} E \) we obtain \( A(\text{cl} E) \approx A(\text{ri}(\text{cl} E)) \). Since \( E \) is nearly convex, we have \( \text{ri} E = \text{ri}(\text{cl} E) \) by Fact 2.14, hence \( A(\text{cl} E) \approx A(\text{ri} E) \), and (ii) holds.
(iii) By (ii) and Fact 2.7 we have
\[ \text{ri}(AE) = \text{ri}[A(\text{cl } E)] = A(\text{ri}(\text{cl } E)) = A(\text{ri } E). \]

\[ \square \]

**Remark 4.3** Theorem 4.2(i)&(iii) was proved in [13, Lemmas 2.3, 2.4], our proof is different from theirs.

**Corollary 4.4** Let \( (\forall i \in I) E_i \) be nearly convex sets in \( \mathbb{R}^n \). Then
\[ \text{ri}(E_1 + \cdots + E_m) = \text{ri } E_1 + \cdots + \text{ri } E_m. \]

**Proof.** Apply Theorem 4.2(iii) and Proposition 4.1(ii) with \( A : (x_1, \ldots, x_m) \mapsto \sum_{i \in I} x_i \) where \( x_i \in \mathbb{R}^n \), and \( E := E_1 \times \cdots \times E_m \). \[ \square \]

**Theorem 4.5** Let \( A : \mathbb{R}^n \to \mathbb{R}^m \) be a linear transformation and let \( E \subseteq \mathbb{R}^m \) be a nearly convex set such that \( A^{-1}(\text{ri } E) \neq \emptyset \). Then

(i) \( A^{-1}E \) is nearly convex,

(ii) \( \text{ri}(A^{-1}E) = A^{-1}(\text{ri } E) \),

(iii) \( \text{cl } [A^{-1}(E)] = A^{-1}(\text{cl } E) \).

**Proof.** As \( E \) is nearly convex, there exists a convex set \( C \) such that \( C \subseteq E \subseteq \text{cl } C \) and \( \text{ri } E = \text{ri } C \). The assumption \( A^{-1}(\text{ri } E) \neq \emptyset \) is equivalent to \( A^{-1}(\text{ri } C) \neq \emptyset \), so \( A^{-1}(\text{ri } C) \neq \emptyset \) by Fact 2.4(iv). Because \( A^{-1}(\text{ri } C) \neq \emptyset \), by Fact 2.8 we have \( \text{cl } [A^{-1}(C)] = A^{-1}(\text{cl } C) \). Then
\[ A^{-1}(C) \subseteq A^{-1}(E) \subseteq A^{-1}(\text{cl } C) \subseteq \text{cl } [A^{-1}(\text{cl } C)] = \text{cl } [A^{-1}(C)] \]
which gives \( A^{-1}(C) \subseteq A^{-1}(E) \subseteq \text{cl } [A^{-1}(E)] \), so (i) holds. It also follows that \( \text{ri}(A^{-1}(E)) = \text{ri}(A^{-1}(C)) \). By Fact 2.8
\[ \text{ri}(A^{-1}(C)) = A^{-1}(\text{ri } C) = A^{-1}(\text{ri } E). \]

Therefore (ii) holds. (iii) follows from
\[ \text{cl } [A^{-1}(E)] = \text{cl } [A^{-1}(C)] = A^{-1}(\text{cl } C) = A^{-1}(\text{cl } E). \]

\[ \square \]

**Remark 4.6** Theorem 4.5 was proven in [13, Theorem 2.2, Corollary 2.1]. However our proof is different.
**Theorem 4.7** Let \( A : \mathbb{R}^n \to \mathbb{R}^m \) be a linear transformation and let \( E \subseteq \mathbb{R}^m \) be a nearly convex set such that \( A^{-1}(\text{ri}\ E) \neq \emptyset \). Then \( A^{-1}(E) \approx A^{-1}(\text{ri}\ E) \approx A^{-1}(\text{cl}\ E) \).

**Proof.** First notice that since \( E \) is nearly convex we have \( \text{ri}\ E \) and \( \text{cl}\ E \) are convex and \( \text{ri}\ E = \text{ri}(\text{cl}\ E) \), hence \( A^{-1}(\text{ri}(\text{cl}\ E)) = A^{-1}(\text{ri}\ E) \neq \emptyset \). Using Fact 2.14 we have

\[
\text{ri}\ E = \text{ri}(\text{ri}\ E). \tag{15}
\]

Applying Fact 2.8 to the convex sets \( \text{ri}\ E \) and \( \text{cl}\ E \) we have

\[
A^{-1}(\text{ri}\ E) = A^{-1}(\text{ri}(\text{ri}\ E)) = \text{ri} A^{-1}(\text{ri}\ E) \tag{16}
\]

\[
A^{-1}(\text{ri}\ E) = A^{-1}(\text{ri}(\text{cl}\ E)) = \text{ri} A^{-1}(\text{cl}\ E). \tag{17}
\]

Since \( \text{ri}\ E \) and \( \text{cl}\ E \) are convex we have

\[
A^{-1}(\text{ri}\ E) \quad \text{and} \quad A^{-1}(\text{cl}\ E) \quad \text{are convex.} \tag{18}
\]

Moreover, it follows from (16) and (17) that \( \text{ri} A^{-1}(\text{ri}\ E) = \text{ri} A^{-1}(\text{cl}\ E) \). Therefore, using Fact 2.15 we conclude that

\[
A^{-1}(\text{ri}\ E) \approx A^{-1}(\text{cl}\ E). \tag{19}
\]

Notice that \( A^{-1}(\text{ri}\ E) \subseteq A^{-1}(E) \subseteq A^{-1}(\text{cl}\ E) \). Therefore using (19) and Fact 2.16 we conclude that \( A^{-1}(E) \approx A^{-1}(\text{ri}\ E) \approx A^{-1}(\text{cl}\ E) \). ■

The next result generalizes Rockafellar’s Fact 2.5 to nearly convex sets. Our proof is different from the one given in [13, Theorem 2.1].

**Corollary 4.8** Let \( E_i \) be nearly convex sets in \( \mathbb{R}^n \) for all \( i \in I \) such that \( \bigcap_{i=1}^m \text{ri}\ E_i \neq \emptyset \). Then the following hold:

(i) \( \bigcap_{i=1}^m E_i \) is nearly convex.

(ii) \( \bigcap_{i=1}^m \text{ri}\ E_i = \text{ri} \bigcap_{i=1}^m E_i. \)

(iii) \( \text{cl} \bigcap_{i=1}^m E_i = \bigcap_{i=1}^m \text{cl}\ E_i. \)

**Proof.** Define \( A : \mathbb{R}^n \to \mathbb{R}^n \times \cdots \times \mathbb{R}^n \) by \( A\mathbf{x} := (\mathbf{x}, \ldots, \mathbf{x}) \) where \( \mathbf{x} \in \mathbb{R}^n \). The set \( E := E_1 \times \cdots \times E_m \) is nearly convex. The results follow by combining Theorems 4.5, 4.7 ■

13
Corollary 4.9 Let $E_1$ and $E_2$ be nearly convex sets in $\mathbb{R}^n$ such that $E_1 \approx E_2$ and let $A : \mathbb{R}^n \to \mathbb{R}^m$ be a linear transformation. The following hold.

(i) $AE_1 \approx AE_2$,

(ii) If $A^{-1}(\text{ri} \ E_1) \neq \emptyset$, then $A^{-1}E_1 \approx A^{-1}E_2$.

Proof. Indeed, since $E_1 \approx E_2$ we have $\text{ri} \ E_1 = \text{ri} \ E_2$. It follows from Theorem 4.2 that

$$AE_1 \approx A(\text{ri} \ E_1) = A(\text{ri} \ E_2) \approx AE_2.$$  \hfill (20)

This gives (i). For (ii) apply Theorem 4.7. \hfill ■

5 Recession cones of nearly convex sets

In this section we extend several of the results for the calculus of recession cones in [24, Chapter 8] to nearly convex sets. Intuitively, it would seem that most recession cone results on convex sets should hold for nearly convex sets. Unfortunately, this is not the case. On the positive side, we establish that $\text{rec} \ E$ of a nearly convex set $E$ is nearly convex provided that $\text{span}(E - E) = \text{rec}(\text{cl} \ E) - \text{rec}(\text{cl} \ E)$.

Fact 5.1 [24, Theorem 8.1] Let $C$ be a nonempty convex subset of $\mathbb{R}^n$. Then $\text{rec} \ C$ is a convex cone and $0 \in \text{rec} \ C$. Moreover,

$$\text{rec} \ C = \{ y \in \mathbb{R}^n \mid y + C \subseteq C \}.$$ \hfill (21)

When $E$ is nonempty nearly convex subset of $\mathbb{R}^n$, the characterization (21) may fail to be equivalent to (1) as illustrated in the following example. Let $\mathbb{N}$ denote the set of natural numbers.

Example 5.2 Suppose that $E := \{ (x, y) \mid y \geq x^2, x \geq 0 \} \setminus \{ (0, 0) \times \mathbb{N} \} \subseteq \mathbb{R}^2$. Notice that the set $\bar{E} = \{ (x, y) \mid y \geq x^2, x \geq 0 \}$ is convex and $E \approx \bar{E}$ and therefore $E$ is nearly convex by Fact 3.1(iii). Clearly $(\forall y \in \{ 0 \} \times \mathbb{N}) \ y + E \subseteq E$, however $y \notin \text{rec} \ E = \{ 0 \}$, since $(\forall \lambda \in \mathbb{R}_+ \setminus \mathbb{N}) \ \lambda y + E \not\subseteq E$.

Lemma 5.3 Let $E$ be a nonempty nearly convex subset in $\mathbb{R}^n$. Then $\text{rec}(\text{ri} \ E) = \text{rec}(\text{cl} \ E)$, in particular, a closed convex cone.
Proof. Since $E$ is nearly convex, it follows that $\text{ri} E$ and $\text{cl} E$ are convex sets. Fact 2.14 gives $\text{ri}(\text{ri} E) = \text{ri} E$ and $\text{cl}(\text{ri} E) = \text{cl} E$. Applying Fact 2.10 to the convex set $\text{ri} E$ we conclude that
\[
\text{rec}(\text{ri} E) = \text{rec}[\text{ri}(\text{ri} E)] = \text{rec}[\text{cl}(\text{ri} E)] = \text{rec}(\text{cl} E).
\] (22)
As $\text{cl} E$ is closed convex, Fact 2.9 completes the proof. ■

**Proposition 5.4** Given $(\forall i \in I) \ E_i \subseteq \mathbb{R}^n$. Then the following hold:

(i) $\text{rec}(E_1 \times \cdots \times E_m) = \text{rec} E_1 \times \cdots \times \text{rec} E_m$.

(ii) If, in addition, each $E_i$ is nearly convex, then
\[
\text{rec}[\text{cl}(E_1 \times \cdots \times E_m)] = \text{rec}(\text{cl} E_1) \times \cdots \times \text{rec}(\text{cl} E_m) = \text{rec}(\text{ri} E_1) \times \cdots \times \text{rec}(\text{ri} E_m).
\]

Proof. (i) This follows from the definition recession cone (1).

(ii) By (i) and Lemma 5.3, we have
\[
\text{rec}[\text{cl}(E_1 \times \cdots \times E_m)] = \text{rec}(\text{cl} E_1) \times \cdots \times \text{rec}(\text{cl} E_m)
\]
\[
= \text{rec}(\text{ri} E_1) \times \cdots \times \text{rec}(\text{ri} E_m).
\]

The following result is folklore, and we omit its proof.

**Fact 5.5** Let $S \subseteq \mathbb{R}^n$ be nonempty, and $K \subseteq \mathbb{R}^n$ be a convex cone. Then the following hold:

(i) The set $S$ is bounded if and only if $\text{cl} S$ is bounded.

(ii) For every $x \in S$,
\[
\text{aff}(S) = \{x\} + \text{span}(S - S).
\] (23)
In addition, if $0 \in S$, then $\text{span} S = \text{aff} S = \text{span}(S - S)$.

(iii) $\text{span}(S - S) = \text{span}(\text{cl} S - \text{cl} S)$.

(iv) $K - K = \text{span} K$.

**Fact 5.6** [24, Theorem 8.4] Let $C$ be a nonempty closed convex subset in $\mathbb{R}^n$. Then $C$ is bounded if and only if $\text{rec} C = \{0\}$. 

15
**Proposition 5.7** Let $E$ be a nonempty nearly convex subset in $\mathbb{R}^n$. Then $E$ is bounded if and only if $\text{rec}(\text{cl} E) = \{0\}$.

**Proof.** Since $E$ is nearly convex, $\text{cl} E$ is a nonempty closed convex. Using Fact 5.5(i) and Fact 5.6 applied to $\text{cl} E$ we conclude that

$$E \text{ is bounded } \iff \text{cl} E \text{ is bounded } \iff \text{rec}(\text{cl} E) = \{0\}. \quad (24)$$

The following example shows that $\text{rec}(\text{cl} E) = \{0\}$ cannot be replaced by $\text{rec} E = \{0\}$.

**Example 5.8** The almost convex set

$$E := \{(x_1, x_2) \mid -1 \leq x_1 \leq 1, x_2 \in \mathbb{R}\} \setminus \{(x_1, x_2) \mid x_1 = \pm 1, -1 < x_2 < 1\}$$

has $\text{rec} E = \{(0, 0)\}$, but $E$ is unbounded.

**Lemma 5.9** Let $S$ be a nonempty subset of $\mathbb{R}^n$. Then $S \subseteq \text{rec}(\text{cl} S)$.

**Proof.** Let $y \in \text{rec} S$ and let $s \in \text{cl} S$. Then $(\exists (s_n)_{n \in \mathbb{N}}) \subseteq S$ such that $s_n \to s$. Since $(\forall n \in \mathbb{N}) s_n \in S$, it follows from that definition of $\text{rec} S$ that $(\forall n \in \mathbb{N}) (\forall \lambda \geq 0) \lambda y + s_n \in S$, hence $\lambda y + s_n \to \lambda y + s \in \text{cl} S$. That is $y \in \text{rec}(\text{cl} S)$, which completes the proof.

We are now ready for the main result of this section.

**Proposition 5.10** Let $E$ be a nonempty nearly convex subset of $\mathbb{R}^n$. Suppose that

$$\text{span}[\text{rec}(\text{cl} E)] = \text{span}(\text{cl} E - \text{cl} E), \quad (25)$$

equivalently,

$$\text{rec}(\text{cl} E) - \text{rec}(\text{cl} E) = \text{span}(E - E). \quad (26)$$

Then the following hold:

(i) $\text{ri}[\text{rec}(\text{cl} E)] \subseteq \text{rec} E$.

(ii) $\text{rec} E$ is nearly convex.

(iii) $\text{rec} E \approx \text{ri}[\text{rec}(\text{cl} E)]$.

(iv) $\text{rec}(\text{ri} E) \approx \text{rec} E \approx \text{rec}(\text{cl} E)$. 

16
Proof. Observe that (25) and (26) are equivalent because of Fact 5.5(iii)&(iv).

(i) Let \( y \in \text{ri}[\text{rec}(\text{cl}E)] \subseteq \text{rec}(\text{cl}E) \). Then \((\exists \epsilon > 0)\) such that

\[
B(y, \epsilon) \cap \text{aff}[\text{rec}(\text{cl}E)] \subseteq \text{rec}(\text{cl}E).
\]

Therefore \((\forall x \in \text{cl}E), x + y \in \text{cl}E, \) and

\[
x + (B(y, \epsilon) \cap \text{aff}[\text{rec}(\text{cl}E)]) \subseteq \text{cl}E.
\]

Using Fact 5.5(ii) (25) and (28) we have

\[
B(x + y, \epsilon) \cap \text{aff}(E) = B(x + y, \epsilon) \cap (x + \text{span}(E - E)) = x + (B(y, \epsilon) \cap \text{span}(E - E)) = x + (B(y, \epsilon) \cap \text{aff}[\text{rec}(\text{cl}E)]) \subseteq \text{cl}E.
\]

That is, \( x + y \in \text{ri}(\text{cl}E) \). Since \( E \) is nearly convex we have \( \text{ri}(\text{cl}E) = \text{ri}E \), hence \( x + y \in \text{ri}E \subseteq E \). In particular, it follows from (29) that \((\forall z \in E) z + y \in E \). Note that \( \text{rec}(\text{cl}E) \) is a cone, and \( \text{aff}[\text{rec}(\text{cl}E)] \) is a subspace. For every \( \lambda > 0, \lambda y \in \text{ri}[\text{rec}(\text{cl}E)] \), multiplying (27) by \( \lambda > 0 \) gives

\[
B(\lambda y, \lambda \epsilon) \cap \text{aff}[\text{rec}(\text{cl}E)] \subseteq \text{rec}(\text{cl}E).
\]

The above arguments show that \((\forall z \in E) z + \lambda y \in E \). Consequently \( y \in \text{rec}E \), as claimed.

(ii)&(iii) Since \( E \) is nearly convex we have \( \text{cl}E \) is a nonempty closed convex set. Therefore by Fact 2.9 and Fact 2.4(i)&(iii) applied to the convex set \( \text{rec}(\text{cl}E) \) we have \( \text{rec}(\text{cl}E) \) is a nonempty closed convex cone, \( \text{ri}[\text{rec}(\text{cl}E)] \) is a nonempty convex set and

\[
\text{rec}(\text{cl}E) = \text{cl}[\text{rec}(\text{cl}E)] = \text{cl}(\text{ri}[\text{rec}(\text{cl}E)]).
\]

It follows from Lemma 5.9 that \( \text{rec}E \subseteq \text{rec}(\text{cl}E) \). Therefore using (i) we have

\[
\text{ri}[\text{rec}(\text{cl}E)] \subseteq \text{rec}E \subseteq \text{rec}(\text{cl}E) = \text{cl}[\text{rec}(\text{cl}E)] = \text{cl}(\text{ri}[\text{rec}(\text{cl}E)]).
\]

Using Fact 2.14 we conclude that \( \text{rec}E \) is nearly convex and \( \text{rec}E \approx \text{ri}[\text{rec}(\text{cl}E)] \), as claimed. (iv) It follows from (30) that

\[
\text{cl}(\text{rec}E) = \text{cl}[\text{rec}(\text{cl}E)].
\]

Since \( \text{rec}E \) is nearly convex by (ii), and \( \text{rec}(\text{cl}E) \) is convex by Fact 2.9, it follows from (31) and Fact 2.15 that \( \text{rec}E \approx \text{rec}(\text{cl}E) \). Now combine with Lemma 5.3.

The following example shows that in Theorem 5.10, condition (25) cannot be removed.
Example 5.11 Suppose that $E$ is as defined in Example 5.2. Then $\{0\} = \text{rec} E \ncong \text{rec} \overline{E} = R_+ \cdot (0, 1)$. Note that (25) fails because $\text{span}(E - E) = \mathbb{R}^2 \neq \{0\} \times \mathbb{R} = \text{span}[\text{rec}(\text{cl} E)]$.

Unfortunately, in general we do not know whether the recession cone of a nearly convex set is nearly convex. We leave this as an open question.

6 Applications

In this section, we apply results in Section 5 and Section 4 to study the maximality of a sum of maximally monotone operators and the closedness of linear images of nearly convex sets.

6.1 Maximality of a sum of maximally monotone operators

Fact 6.1 (See, e.g., [26, Corollary 12.44].) Let $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ and $B : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be maximally monotone such that $\text{ri dom} A \cap \text{ri dom} B \neq \emptyset$. Then $A + B$ is maximally monotone.

One can apply Fact 6.1 and Corollary 4.8 to show the following well-known result.

Theorem 6.2 Let $\{ A_i \}_{i \in I}$ be finite family of maximally monotone operators from $\mathbb{R}^n \rightrightarrows \mathbb{R}^n$ such that $\cap_{i=1}^m \text{ri dom} A_i \neq \emptyset$. Then $A_1 + \cdots + A_m$ is maximally monotone.

Proof. We proceed via induction. When $m = 2$, the proof follows from Fact 6.1. Next, assume that for $m \in \mathbb{N}$ with $m \geq 2$ we have $\cap_{i=1}^m \text{ri}(\text{dom} A_i) \neq \emptyset$ implies that $A_1 + \cdots + A_m$ is maximally monotone. Now suppose that $\cap_{i=1}^{m+1} \text{ri}(\text{dom} A_i) \neq \emptyset$. By Fact 2.17, for all $i \in \{1, \ldots, m+1\}$, dom $A_i$ is nearly convex set. Moreover, by Corollary 4.8(ii),

$$\cap_{i=1}^{m+1} \text{ri dom} A_i = \cap_{i=1}^m \text{ri dom} A_i \cap \text{ri dom} A_{m+1} = \text{ri} (\cap_{i=1}^m \text{dom} A_i) \cap \text{ri dom} A_{m+1} = \text{ri dom}(A_1 + \cdots + A_m) \cap \text{ri dom} A_{m+1}.$$ 

Therefore, $\cap_{i=1}^{m+1} \text{ri dom} A_i \neq \emptyset$ implies that $\cap_{i=1}^m \text{ri dom} A_i \neq \emptyset$ and that $\text{ri dom}(A_1 + \cdots + A_m) \cap \text{ri dom} A_{m+1} \neq \emptyset$. By the inductive hypothesis we have $A_1 + \cdots + A_m$ is maximally monotone. The proof then follows from applying Fact 6.1 to the maximally monotone operators $A_1 + \cdots + A_m$ and $A_{m+1}$. \qed
6.2 Further closedness results

**Theorem 6.3** Let \( E \) be a nonempty nearly convex subset in \( \mathbb{R}^n \) and let \( A \) be a linear transformation from \( \mathbb{R}^n \) to \( \mathbb{R}^m \). Suppose that \( (\forall z \in \text{rec}(\text{cl} E) \setminus \{0\}) \) with \( Az = 0 \) we have that \( z \) belongs to the lineality space of \( \text{cl} E \). Then

\[
\text{cl} AE = A(\text{cl} E),
\]

and

\[
\text{rec} A(\text{cl} E) = A(\text{rec}(\text{cl} E)).
\]

**Proof.** Since \( E \) is nonempty and nearly convex, it follows from Fact 2.14 that \( \text{ri} E \) is a nonempty convex subset and \( \text{cl} (\text{ri} E) = \text{cl} E \). Therefore by assumption on \( E \) we have \( (\forall z \in \text{rec}(\text{cl} (\text{ri} E)) \setminus \{0\} = \text{rec}(\text{cl} E) \setminus \{0\}) \) with \( Az = 0 \) we have that \( z \) belongs to the lineality space of \( \text{cl} (\text{ri} E) = \text{cl} E \). Using Theorem 4.2(ii) we have

\[
\text{cl} AE = \text{cl} [A(\text{ri} E)].
\] \hspace{1cm} (32)

Using (32), Fact 2.11 applied to the nonempty convex set \( \text{ri} E \), and Fact 2.14 we obtain

\[
\begin{align*}
\text{cl} AE &= \text{cl} [A(\text{ri} E)] = A(\text{cl} (\text{ri} E)) = A(\text{cl} E), \\
\text{rec} A(\text{cl} E) &= \text{rec} A(\text{cl} (\text{ri} E)) = A(\text{rec}(\text{cl} (\text{ri} E))) = A(\text{rec}(\text{cl} E)),
\end{align*}
\] \hspace{1cm} (33)

as claimed. \hspace{1cm} ■

As a consequence, we have:

**Corollary 6.4** Let \( (E_i)_{i \in I} \) be a family of nonempty nearly convex subsets in \( \mathbb{R}^n \) satisfying the following condition: if \( (\forall i \in I)(\exists z_i \in \text{rec}(\text{cl} E_i)) \) and \( \sum_{i \in I} z_i = 0 \) then \( (\forall i \in I)z_i \) belongs to the lineality space of \( \text{cl} E_i \). Then

\[
\text{cl} (E_1 + \cdots + E_m) = \text{cl} E_1 + \cdots + \text{cl} E_m = \text{cl} (\text{ri} E_1) + \cdots + \text{cl} (\text{ri} E_m),
\]

and

\[
\text{rec}[\text{cl} (E_1 + \cdots + E_m)] = \text{rec}(\text{cl} E_1) + \cdots + \text{rec}(\text{cl} E_m) = \text{rec}(\text{ri} E_1) + \cdots + \text{rec}(\text{ri} E_m).
\]

**Proof.** Define a linear mapping \( A : \mathbb{R}^n \times \cdots \times \mathbb{R}^n \rightarrow \mathbb{R}^n \) by \( A(x_1, \ldots, x_m) := x_1 + \cdots + x_m \) where \( x_i \in \mathbb{R}^n \). The set \( E := E_1 \times \cdots \times E_m \) is nearly convex in \( \mathbb{R}^n \times \cdots \times \mathbb{R}^n \). It suffices to apply Theorem 6.3, Lemma 5.3, and Proposition 5.4. \hspace{1cm} ■

Corollary 6.4 generalizes Fact 2.12 from convex sets to nearly convex sets.
7 Examples of nearly convex sets as ranges or domains of subdifferential operators

It is natural to ask: is every nearly convex set a domain or a range of the subdifferential of a lower semicontinuous convex function, or a domain or a range of a maximally monotone operator? While we cannot answer the question, we construct some interesting proper lower semicontinuous convex functions with prescribed domains or ranges of subdifferentials. Our constructions rely on the sum rule of subdifferentials for a sum of convex functions, while each convex function has a subdifferential domain with specific properties.

Recall that for a proper lower semicontinuous convex function \( f : \mathbb{R}^n \rightarrow ]-\infty, +\infty] \), its subdifferential at \( x \in \mathbb{R}^n \) is

\[
\partial f(x) := \{ u \in \mathbb{R}^n \mid (\forall y \in \mathbb{R}^n) \langle y - x, u \rangle + f(x) \leq f(y) \}
\]

when \( f(x) < +\infty \); and \( \partial f(x) := \emptyset \) when \( f(x) = +\infty \). If \( f \) is continuous at \( x \) (e.g., when \( x \in \text{int dom } f \)), then \( \partial f(x) \neq \emptyset \); if \( f \) is differentiable at \( x \), then \( \partial f(x) = \{ \nabla f(x) \} \). Fact 8.2 provides a convenient tool to compute \( \partial f \). A celebrated result due to Rockafellar states that the subdifferential mapping \( \partial f \) is a maximally monotone operator, see, e.g., [26, Theorem 12.17], [28, Theorem 3.1.11]. In [24, page 218], Rockafellar gave a proper lower semicontinuous convex function whose subdifferential domain is not convex. (Rockafellar’s function is Example 7.5 when \( \alpha = 1 \).) According to Fact 2.17, \( \text{dom } \partial f \) must be nearly convex. The Fenchel conjugate \( f^* \) of \( f \) is defined by

\[
(\forall x^* \in \mathbb{R}^n) \quad f^*(x^*) := \sup \{ \langle x^*, x \rangle - f(x) \mid x \in \mathbb{R}^n \}.
\]

The conjugate \( f^* \) is a proper lower semicontinuous convex function as long as \( f \) is, and \( \partial f^* = (\partial f)^{-1} \). The indicator function of a set \( C \subseteq \mathbb{R}^n \) is

\[
\iota_C(x) := \begin{cases} 
0 & \text{if } x \in C; \\
+\infty & \text{otherwise.}
\end{cases}
\]

A brief orientation about our main achievements in this section is as follows. We show that: Every open or closed convex set in \( \mathbb{R}^n \) is a domain of a subdifferential mapping, so are their intersections under a constraint qualification; Every nearly convex set in \( \mathbb{R} \) is a domain of a subdifferential mapping; In \( \mathbb{R}^2 \) every polyhedral sets with its edges removed but keeping its vertices is a domain of a subdifferential mapping.
7.1 Some general results

A set $A \subseteq \mathbb{R}^n$ is absorbing if for every $x \in \mathbb{R}^n$ there exists $s_x$ such that $x \in tA$ when $t > s_x$. Define the gauge function of $A$ by

$$\rho_A(x) := \inf \{ t \mid t > 0, x \in tA \}.$$ 

Then $\rho_A$ is finite-valued, nonnegative, and positive homogeneous.

**Theorem 7.1** Let $C \subseteq \mathbb{R}^n$ be open convex set. Then there exists a lower semicontinuous convex function $g : \mathbb{R}^n \to ]-\infty, +\infty]$ such that such that $\text{ran } \partial g = C$, equivalently, $\text{dom } \partial g^* = C$.

**Proof.** Take $x_0 \in C$, and let $A := C - x_0$. Define the lower semicontinuous convex function

$$g(x) := \begin{cases} \frac{1}{1 - \rho_A(x)} & \text{if } x \in A, \\ +\infty & \text{otherwise.} \end{cases}$$

The convexity of $g$ follows from that $\rho_A$ is a finite-valued convex function on $\mathbb{R}^n$, $A = \{ x \in \mathbb{R}^n \mid \rho_A(x) < 1 \}$ by [15] Exercise 2.15, and that $t \mapsto \frac{1}{1-t}$ is increasing and convex on $[0, 1)$. Since

$$\partial g(x) = \begin{cases} \frac{\partial \rho_A(x)}{(1 - \rho_A(x))^2} & (\forall x \in A), \\ \emptyset & \text{otherwise,} \end{cases}$$

we have $\text{dom } \partial g = A$, so $\text{ran } \partial g^* = \text{ran}(\partial g)^{-1} = A$. Then $\text{ran } (g^* + \langle x_0, \cdot \rangle) = A + x_0 = C$. $\blacksquare$

**Theorem 7.2** Every nonempty closed convex set $C \subseteq \mathbb{R}^n$ is a domain or range of a subdifferential mapping of a proper lower semicontinuous convex function.

**Proof.** The proper lower semicontinuous convex function $i_C$ has $\partial i_C = N_C$ so that $\text{dom } \partial i_C = C$. Its Fenchel conjugate $\sigma_C := i^*_C$ has $\text{ran } \partial \sigma_C = \text{ran}(\partial i_C)^{-1} = C$. $\blacksquare$

**Corollary 7.3** Assume that $(\forall i = 1, \ldots, m)$ $O_i \subseteq \mathbb{R}^n$ is open convex, that $(\forall j = 1, \ldots, k)$ $F_j \subseteq \mathbb{R}^n$ is closed convex, and that

$$(\cap_{i=1}^m O_i) \cap (\cap_{j=1}^k F_j) \neq \emptyset. \quad (34)$$

Then there exists a lower semicontinuous convex function $f : \mathbb{R}^n \to ]-\infty, +\infty]$ such that $\text{dom } \partial f = (\cap_{i=1}^m O_i) \cap (\cap_{j=1}^k F_j)$, equivalently, $\text{ran } \partial f^* = (\cap_{i=1}^m O_i) \cap (\cap_{j=1}^k F_j)$. 

21
Proof. Without loss of generality, we can assume $0 \in \bigcap_{i=1}^{m}O_{i}\cap \text{ri} \bigcap_{j=1}^{k}F_{j}$. For each $O_{i}$, as in Theorem 7.1 define a lower semicontinuous convex function

$$g_{i}(x) := \begin{cases} 
\frac{1}{1-\rho_{O_{i}}(x)} & \text{if } x \in O_{i}, \\
+\infty & \text{otherwise}.
\end{cases}$$

For each $F_{j}$, as in Theorem 7.2 define a lower semicontinuous convex function $\iota_{F_{j}}$. For the lower semicontinuous convex function

$$f := g_{1} + \cdots + g_{m} + \iota_{F_{1}} + \cdots + \iota_{F_{k}},$$

the constraint qualification (34) guarantees that the subdifferential sum rule applies, see, e.g., [24, Theorem 23.8] or [4, Corollary 16.39]. This gives

$$\partial f = \partial g_{1} + \cdots + \partial g_{m} + \partial \iota_{F_{1}} + \cdots + \partial \iota_{F_{k}}.$$

Therefore, the subdifferential operator $\partial f$ has

$$\text{dom } \partial f = (\bigcap_{i=1}^{m} \text{dom } \partial g_{i}) \bigcap (\bigcap_{j=1}^{k} \text{dom } \partial \iota_{F_{j}}) = (\bigcap_{i=1}^{m}O_{i}) \bigcap (\bigcap_{j=1}^{k}F_{j}).$$

\[\blacksquare\]

7.2 Nearly convex sets in $\mathbb{R}$

Suppose that $C$ is a nonempty nearly convex subset of $\mathbb{R}$. Then either $C$ is a singleton or $C$ is an interval, and consequently $C$ is convex.

**Theorem 7.4** Suppose that $C$ is a nonempty nearly convex (hence convex) subset of $\mathbb{R}$. Then there exists a proper lower semicontinuous convex function $f : \mathbb{R} \to ]-\infty, +\infty]$ such that $\text{dom } \partial f = C$. Consequently, $\text{ran } \partial f^{*} = C$.

**Proof.** We argue by cases.

Case (i): $C$ is closed. This covers $C := (-\infty, +\infty), (-\infty, b], [a, +\infty), [a, b]$ where $a, b \in \mathbb{R}$. We let $f := \iota_{C}$. Then $\partial f = N_{C}$ has $\text{dom } \partial f = C$.

Case (ii): $C := (a, +\infty)$ or $(-\infty, b)$. We only consider $C = (a, +\infty)$, since the arguments for $C := (-\infty, b)$ is similar. Let

$$f(x) := \begin{cases} 
\frac{1}{x-a} & \text{if } x > a, \\
+\infty & \text{otherwise}.
\end{cases}$$
Then 
\[ \partial f(x) = \begin{cases} 
-\frac{1}{(x-a)^2} & \text{if } x > a, \\
\emptyset & \text{otherwise}, 
\end{cases} \]
has \( \text{dom} \, \partial f = (a, +\infty) \).

In the remaining cases, we can and do assume \( a, b \in \mathbb{R} \).

Case (iii): If \( C := ]a, b[ \) with \( a, b \in \mathbb{R} \) and \( a < b \), we put
\[
\begin{align*}
f(x) := \begin{cases} 
\left(-\frac{b-a}{\pi}\ln\cos\left(\frac{\pi(x-a)}{b-a} - \frac{\pi}{2}\right) \right) & \text{if } a < x < b, \\
+\infty & \text{otherwise}.
\end{cases}
\end{align*}
\]
Then
\[
\partial f(x) = \begin{cases} 
\tan\left(\frac{\pi}{b-a}(x-a) - \frac{\pi}{2}\right) & \text{if } a < x < b, \\
\emptyset & \text{otherwise}.
\end{cases}
\]
has \( \text{dom} \, \partial f = (a, b) \).

Case (iv): \( C \) is half-open interval. Suppose without loss of generality that \( C := ]a, b] \) with \( a, b \in \mathbb{R} \) and \( a < b \). We put
\[
\begin{align*}
f(x) := \begin{cases} 
-(\ln(x-a) - \frac{x}{b-a}) & \text{if } a < x \leq b, \\
+\infty & \text{otherwise}.
\end{cases}
\end{align*}
\]
Then
\[
\partial f(x) = \begin{cases} 
\frac{1}{a-x} - \frac{1}{a-b} & \text{if } a < x < b, \\
[0, +\infty] & \text{if } x = b, \\
\emptyset & \text{otherwise}.
\end{cases} \tag{35}
\]
has \( \text{dom} \, \partial f = (a, b] \).

\[7.3\] Nearly convex sets in \( \mathbb{R}^2 \)

We start with a complete analysis of the classical example by Rockafellar \([24, \text{page } 218]\). Often in literature, it only gives that \( \text{dom} \, \partial f \) is not convex without details. His function is modified for the convenience of our later constructions. The set of nonpositive real numbers is \( \mathbb{R}_- := \{ x \in \mathbb{R} \mid x \leq 0 \} \).
Example 7.5 Let \( \alpha > 0 \) and define \( f(\xi_1, \xi_2) : \mathbb{R}^2 \to [-\infty, +\infty] \) by

\[
f(\xi_1, \xi_2) := \begin{cases}
\max \left\{ \alpha - \frac{1}{2} \xi_1^2, |\xi_2| \right\} & \text{if } \xi_1 \geq 0, \\
+\infty & \text{otherwise}.
\end{cases}
\] (36)

Then \( \partial f(\xi_1, \xi_2) = \)

\[
\begin{cases}
\emptyset & \text{if } \xi_1 < 0, \\
\emptyset & \text{if } \xi_1 = 0, \text{ and } |\xi_2| < \alpha, \\
\mathbb{R}_- \times \{1\} & \text{if } \xi_1 = 0, \text{ and } \xi_2 \geq \alpha, \\
\mathbb{R}_- \times \{-1\} & \text{if } \xi_1 = 0, \text{ and } \xi_2 \leq -\alpha, \\
\text{conv} \left\{ \left( -\frac{1}{2} \xi_1^{-1/2}, 0 \right), (0,1) \right\} & \text{if } \xi_2 = \alpha - \sqrt{\xi_1}, \text{ and } 0 < \xi_1 < \alpha^2, \\
\text{conv} \left\{ \left( -\frac{1}{2} \xi_1^{-1/2}, 0 \right), (0,-1) \right\} & \text{if } -\xi_2 = \alpha - \sqrt{\xi_1}, \text{ and } 0 < \xi_1 < \alpha^2, \\
\left( -\frac{1}{2} \xi_1^{-1/2}, 0 \right) & \text{if } 0 < \xi_1 < \alpha^2, \text{ and } \alpha - \sqrt{\xi_1} > |\xi_2|, \\
(0,1) & \text{if } 0 < \xi_1 < \alpha^2, \text{ and } \xi_2 > \alpha - \sqrt{\xi_1}, \\
(0,-1) & \text{if } 0 < \xi_1 < \alpha^2, \text{ and } -\xi_2 > \alpha - \sqrt{\xi_1}, \\
\text{conv} \left\{ \left( -\frac{1}{2} \xi_1^{-1/2}, 0 \right), (0,1), (0,-1) \right\} & \text{if } \xi_1 = \alpha^2, \text{ and } \xi_2 = 0, \\
\text{conv} \left\{ (0,1), (0,-1) \right\} & \text{if } \xi_1 > \alpha^2, \text{ and } \xi_2 = 0, \\
(0,1) & \text{if } \xi_1 > \alpha^2, \text{ and } \xi_2 > 0, \\
(0,-1) & \text{if } \xi_1 > \alpha^2, \text{ and } -\xi_2 > 0.
\end{cases}
\] (37)

Consequently,

\[
\text{ran } \partial f = \{ (\xi_1, \xi_2) \mid \xi_1 \leq 0, |\xi_2| \leq 1 \},
\] (38)

and the domain of \( \partial f \)

\[
\text{dom } \partial f = \{ (\xi_1, \xi_2) \mid \xi_1 > 0, \xi_2 \in \mathbb{R} \} \cup \{ (0, \xi_2) \mid |\xi_2| \geq \alpha \}
\] (39)

is almost convex but not convex. Moreover, the Fenchel conjugate of \( f \) is \( f^*(x_1^*, x_2^*) = \)

\[
\begin{cases}
0 & \text{if } x_1^* \leq 0 \text{ and } |x_2^*| = 1, \text{ or } x_1^* = 0 \text{ and } |x_2^*| < 1, \\
\alpha^2 x_1^* & \text{if } \frac{1}{2\alpha} \leq x_1^* \leq 0, \text{ and } |x_2^*| \leq 1 + 2\alpha x_1^*, \\
-\frac{(1-|x_2^*|)^2}{4x_1^2} - \alpha (1 - |x_2^*|) & \text{if } x_1^* < 0, \text{ and } \max\{0, 1 + 2\alpha x_1^*\} \leq x_2^* \leq 1, \\
-\frac{(1-|x_2^*|)^2}{4x_1^2} - \alpha (1 - |x_2^*|) & \text{if } x_1^* < 0, \text{ and } -1 \leq x_2^* \leq \min\{0, -(1 + 2\alpha x_1^*)\}, \\
+\infty & \text{otherwise}.
\end{cases}
\] (40)
See Appendix A for its proof. A different example is given in [7].

Figure 2: A Maple [20] snapshot. Left: Plot of \( f \) with \( \alpha = 1 \). Right: Plot of \( f^* \) with \( \alpha = 1 \).

**Example 7.6** Let \( \alpha \geq 0 \). Define \( f : \mathbb{R}^2 \to ]-\infty, +\infty[ \) by

\[
  f(x_1, x_2) := \begin{cases} 
  \max\{\alpha - \sqrt{x_1}, x_2\} & \text{if } x_1 \geq 0, \\
  +\infty & \text{otherwise}.
  \end{cases}
\]

Then

\[
  \partial f(x_1, x_2) = \begin{cases} 
  (-1/2x_1^{-1/2}, 0) & \text{if } x_1 > 0, \text{ and } x_2 < \alpha - \sqrt{x_1}, \\
  \text{conv}\{(0,1), (-1/2x_1^{-1/2}, 0)\} & \text{if } x_1 > 0, \text{ and } x_2 = \alpha - \sqrt{x_1}, \\
  \{(0,1)\} & \text{if } x_1 > 0, \text{ and } x_2 > \alpha - \sqrt{x_1}, \\
  \emptyset & \text{if } x_1 = 0, \text{ and } x_2 < \alpha, \\
  \mathbb{R}_- \times \{1\} & \text{if } x_1 = 0, \text{ and } x_2 \geq \alpha, \\
  \emptyset & \text{if } x_1 < 0.
  \end{cases}
\]

In particular, \( \text{dom} \partial f = \{(x_1, x_2) \mid x_1 \geq 0\} \setminus \{(0, x_2) \mid x_2 < \alpha\} \) is neither open nor closed, but it is convex. The same holds for the range

\[
  \text{ran} \partial f = \{(x_1, x_2) \mid x_1 \leq 0, 0 \leq x_2 \leq 1\} \setminus \{(0, x_2) \mid 0 \leq x_2 < 1\}.
\]

See Appendix A for its proof.
We are finally positioned to construct proper lower semicontinuous convex functions on $\mathbb{R}^2$ whose subdifferential domains are nearly polyhedral sets but nonconvex. Recall that $C \subseteq \mathbb{R}^n$ is said to be polyhedral if it can be expressed as the intersection of a finite family closed half spaces or hyperplanes, i.e.,

$$C = \left( \cap_{i=1}^m \{ x \in \mathbb{R}^n | f_i(x) \leq 0 \} \right) \cap \left( \cap_{j=1}^k \{ x \in \mathbb{R}^n | f_j(x) = 0 \} \right)$$

where each $f_i$ is affine.

**Theorem 7.7** In $\mathbb{R}^2$, every polyhedral set $C$ having a nonempty interior and having edges removed but keeping all its vertices is a domain of a subdifferential mapping of a proper lower semicontinuous convex function on $\mathbb{R}^2$.

**Proof.** Each polyhedral set is closed and convex [26 Example 2.10]. Associated each edge $[x_i, x_{i+1}]$ of $C$, one can find a closed half space $H_i \subseteq \mathbb{R}^2$ contains $C$ and has $[x_i, x_{i+1}]$ in its boundary. By using translation, rotation, and dilation for the convex function in Example 7.5, we can get a lower semicontinuous convex function $f_i : \mathbb{R}^2 \to ]-\infty, +\infty]$ such that $\text{dom} \partial f_i = H_i \setminus [x_i, x_{i+1}]$. For each edge of the form emanating from $x_j$ in the direction $v_j$: $R_j = \{ x_j + \tau v_j \mid \tau \geq 0 \}$, one can find a closed half space $H_j \subseteq \mathbb{R}^2$ containing $C$ and has $R_j$ in its boundary. Again, by using translation, rotation, and dilation for the convex function in Example 7.6, we get a lower semicontinuous convex function $f_j : \mathbb{R}^2 \to ]-\infty, +\infty]$ such that $\text{dom} \partial f_j = H_j \setminus \{ x_j + \tau v_j \mid \tau > 0 \}$. Define the lower semicontinuous convex function $f : \mathbb{R}^2 \to ]-\infty, +\infty]$ by

$$f := \iota_{\text{cl}C} + \sum_{i \in I} f_i + \sum_{j \in J} f_j.$$

As $\text{int} C \neq \emptyset$, by the subdifferential sum rule we have $\partial f = \partial \iota_{\text{cl}C} + \sum_{i \in I} \partial f_i + \sum_{j \in J} \partial f_j$. The maximally monotone operator $\partial f$ has $\text{dom} \partial f = C$. $\blacksquare$

Immediately from Theorem 7.7 we see that each set in Figure 3 is the subdifferential domain of a proper lower semicontinuous convex function on $\mathbb{R}^2$. 

---

26
As a concrete example, we have

**Example 7.8** Suppose that \( f : \mathbb{R}^2 \to [\pm \infty) \) is defined as \( f := \sum_{i \in I} f_i \), where \( I := \{1, 2, 3, 4\} \) and \((\forall i \in I) f_i \) are defined as

\[
\begin{align*}
  f_1 : \mathbb{R}^2 &\to \mathbb{R} : (x, y) \mapsto \max \left\{ \sqrt{2} - \sqrt{\frac{1}{\sqrt{2}} (2 + x - y)}, \frac{1}{\sqrt{2}} (2 + x + y) \right\}, \\
  f_2 : \mathbb{R}^2 &\to \mathbb{R} : (x, y) \mapsto \max \left\{ 3 - \sqrt{1 + y}, |x| \right\}, \\
  f_3 : \mathbb{R}^2 &\to \mathbb{R} : (x, y) \mapsto \max \left\{ 1 - \sqrt{1 - y}, |x| \right\}, \\
  f_4 : \mathbb{R}^2 &\to \mathbb{R} : (x, y) \mapsto \max \left\{ \sqrt{2} - \sqrt{\frac{1}{\sqrt{2}} (2 - x - y)}, \frac{1}{\sqrt{2}} (-2 + x - y) \right\}.
\end{align*}
\]

Then \( f \) is a proper, convex, lower semicontinuous function and

\[
\text{dom } \partial f = \text{ran}(\partial f)^{-1} = \text{ran } \partial f^* = \{(x, y) \mid |x| < 3, |y| < 1, 2 + x - y > 0, 2 - x - y > 0\} \cup \{(1, 1), (-1, 1), (3, -1), (-3, -1)\},
\]

as shown in Figure 4.
Figure 4: The function $f$ and $\text{dom } \partial f$ of Example 7.8.

Proof. Let

$$g_\alpha : \mathbb{R}^2 \to \mathbb{R} : (x, y) \mapsto \begin{cases} \max \{ \alpha - \sqrt{x}, |y| \}, & \text{if } x \geq 0; \\ +\infty, & \text{otherwise}, \end{cases}$$

and

$$R_\theta = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}.$$ 

Then (\forall (x, y) \in \mathbb{R}^2) we have,

$$f_1(x, y) = g_\sqrt{2}(R_{\pi/4}((x, y) - (-2, 0))),$$
$$f_2(x, y) = g_3(R_{-\pi/2}((x, y) - (0, -1))),$$
$$f_3(x, y) = g_1(R_{\pi/2}((x, y) - (0, 1))),$$
$$f_4(x, y) = g_\sqrt{2}(R_{5\pi/4}((x, y) - (2, 0))).$$

As $\partial f = \sum_{i \in I} \partial f_i$, using Example 7.5 and particularly (39), we see that

$$\text{dom } \partial f = \cap_{i \in I} \text{dom } \partial f_i$$
$$= \{(x, y) \mid |x| < 3, |y| < 1, 2 + x - y > 0, 2 - x - y > 0\} \cup \{(1, 1), (-1, 1), (3, -1), (-3, -1)\}.$$ 

Using [4, Proposition 16.24] we have $(\partial f)^{-1} = \partial f^*$, which completes the proof. ■

We finish this section by remarking that each set in Figure 1 is a subdifferential domain of a proper lower semicontinuous convex function. For the first set, use $f := t_{B(0, 1)} +$
$g_1 + g_2$ where each $g_i$ has dom $\partial g_i$ being an open convex set whose boundary consists of one dotted line part of the unit circle and two dotted rays tangent to the circle. For the second set, use $f := t_{B(0,1)} + g_1 + g_2$ where each $g_i$ is obtained by rotation and translation of Rockafellar’s function, and dom $\partial g_i$ is a closed half space with an open line segment on its boundary removed.

8 Discussions and open problems

In this paper we systematically study nearly convex sets: criteria for near convexity; topological properties such as relative interior, interior, recession cone of nearly convex sets; formulas for the relative interiors and closures of nearly convex sets, which are linear image or inverse image of other nearly convex sets. Rockafellar provided the first convex function whose subdifferential domain is not convex. To build more examples, we compute the subdifferential and the Fenchel conjugate of an modified Rockafellar’s function. It turns out every polyhedral set in $\mathbb{R}^2$ with edges removed but keeping its vertices is a domain of the subdifferential mapping of a proper lower semicontinuous convex function.

Although we have constructed some proper lower semicontinuous convex functions whose subdifferential mappings have prescribed domain or ranges, the general problem is still unsolved. Let us note that

**Theorem 8.1** Let $C \subseteq \mathbb{R}^n$ (not necessarily convex). Then there exists a monotone operator (not necessarily maximal monotone) $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ such that ran $A = C$.

**Proof.** Consider the projection operator $P_C : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. Then $P_C$ is monotone because $\text{gra} \ P_C \subseteq \text{gra} \ P_{cl C}$, and $P_{cl C}$ is monotone by [26, Proposition 12.19]. Clearly ran $P_C = C$.

According to [26, Theorem 12.20], a closed set $C \subseteq \mathbb{R}^n$ is convex if and only if $P_C$ is maximally monotone. Therefore, it is the maximality to force $C$ having more structural properties.

We finish the paper with three open questions:

(i) Is every convex set a domain or range of a subdifferential mapping of a proper lower semicontinuous convex function (or a maximally monotone operator) in $\mathbb{R}^n$ with $n \geq 2$?

(ii) Is every nearly convex set a domain or range of a subdifferential mapping of a
proper lower semicontinuous convex function (or a maximally monotone operator) in $\mathbb{R}^n$ with $n \geq 2$?

(iii) What is the intrinsic difference between the ranges of subdifferentials of proper lower semicontinuous convex functions and the ranges of maximally monotone operators?

**Appendix A**

We shall need two facts. The first one is a structural characterization of $\partial f$ when a convex function $f$ is lower semicontinuous, and $\nabla f$ is not empty. (See also [26, Theorem 12.67] for the structure of maximally monotone operators.) The second one concerns the domain of the Fenchel conjugate of convex functions.

**Fact 8.2** ([24, Theorem 25.6]) Let $f$ be a closed proper convex function such that $\text{dom } f$ has a non-empty interior. Then

$$\partial f(x) = \text{cl}(\text{conv } S(x)) + K(x), \quad \forall x,$$

where $K(x)$ is the normal cone to $\text{dom } f$ at $x$ (empty if $x \not\in \text{dom } f$) and $S(x)$ is the set of all limits of sequence of the form $\nabla f(x_1), \nabla f(x_2), \ldots$, such that $f$ is differentiable at $x_i$, and $x_i$ tends to $x$.

**Lemma 8.3** Assume that $f : \mathbb{R}^n \rightarrow ]-\infty, +\infty]$ is proper lower semicontinuous convex function. If $\text{ran } \partial f$ is closed, then $\text{dom } f^* = \text{ran } \partial f$.

**Proof.** As $\text{ran } \partial f = \text{dom } \partial f^*$, by the Bronsted-Rockafellar’s theorem [23, Theorem 3.17] or [4, Proposition 16.28], we obtain $\text{ran } \partial f \subseteq \text{dom } f^* \subseteq \text{cl}(\text{ran } \partial f)$. Therefore, the result holds.

**I. Proof of Example 7.5**

**Proof.** First, we calculate $\partial f$. We argue by cases:
(i) \( \alpha - \sqrt{\xi_1} > |\xi_2|, \ 0 < \xi_1 < \alpha^2: \nabla f(\xi_1, \xi_2) = \left\{ \left(-\frac{1}{2}\xi_1^{-1/2}, 0\right) \right\} \) because \( f(\xi_1, \xi_2) = \alpha - \xi_1^{1/2} \).

(ii) \( \xi_1 = 0, |\xi_2| < \alpha: \partial f(0, \xi_2) = \emptyset. \) Indeed, by \( \lim_{(x_1, x_2) \to (0, \xi_2)} \nabla f(x_1, x_2) = \lim_{(x_1, x_2) \to (0, \xi_2)} (-\frac{1}{2}x_1^{-1/2}, 0) \) does not exists. Apply Fact 8.2

(iii) \( \xi_1 = 0, \xi_2 \geq \alpha: \partial f(0, \xi_2) = \mathbb{R}_+ \times \{1\}. \) Note that \( \text{dom} f(0, \xi_2) = \mathbb{R}_+ \times \{0\}. \) When \( x_2 > \alpha - \sqrt{\xi_1}, a^2 > x_1 > 0, \) we have \( f(x_1, x_2) = x_2, \) so

\[
\lim_{(x_1, x_2) \to (0, \xi_2)} \nabla f(x_1, x_2) = \{0, 1\};
\]

When \( \alpha - \sqrt{\xi_1} > x_2, 0 < x_1 < \alpha^2, x_2 > 0, \) we have \( f(x_1, x_2) = \alpha - x_1^{1/2}, \) so

\[
\lim_{(x_1, x_2) \to (0, \xi_2)} \nabla f(x_1, x_2) = \lim_{(x_1, x_2) \to (0, \xi_2)} (-\frac{1}{2}x_1^{-1/2}, 0)
\]
does not exist. Apply Fact 8.2 to obtain \( \partial f(0, \xi_2). \)

(iv) \( \xi_1 = 0, \xi_2 \leq -\alpha: \partial f(0, \xi_2) = \mathbb{R}_- \times \{-1\}. \) The arguments are similar to (iii)

(v) \( \xi_2 > \alpha - \sqrt{\xi_1}, a^2 > \xi_1 > 0: \partial f(\xi_1, \xi_2) = \{(0, 1)\} \) because \( f(\xi_1, \xi_2) = \xi_2. \)

(vi) \( \xi_2 = \alpha - \sqrt{\xi_1}, a^2 > \xi_1 > 0: \) Notice that \( f(\xi_1, \xi_2) = \max\{f_1(\xi_1, \xi_2), f_2(\xi_1, \xi_2)\}, \) where \( f_1(\xi_1, \xi_2) = \alpha - \sqrt{\xi_1} \) and \( f_2(\xi_1, \xi_2) = \xi_2. \) When \( |\xi_2| = \alpha - \sqrt{\xi_1}, \xi_1 > 0, \) and \( \xi_2 > 0, \) we have \( f_1(\xi_1, \xi_2) = f_2(\xi_1, \xi_2), \) hence it follows from [26, Theorem 10.31] that

\[
\partial f(\xi_1, \xi_2) = \text{conv} \{\nabla f_1(\xi_1, \xi_2), \nabla f_1(\xi_1, \xi_2)\} = \text{conv} \left\{ \left(-\frac{1}{2}\xi_1^{-1/2}, -\frac{1}{2}\xi_1^{-1/2}, 0\right), (0, 1) \right\}.
\]

(vii) \( -\xi_2 = \alpha - \sqrt{\xi_1}, a^2 > \xi_1 > 0: \) The proof is similar to the previous case with \( f(\xi_1, \xi_2) = \max\{f_1(\xi_1, \xi_2), f_2(\xi_1, \xi_2)\}, \) where \( f_1(\xi_1, \xi_2) = \alpha - \sqrt{\xi_1}, \) and \( f_2(\xi_1, \xi_2) = -\xi_2, \) thus

\[
\partial f(\xi_1, \xi_2) = \text{conv} \left\{ \left(-\frac{1}{2}\xi_1^{-1/2}, 0\right), (0, -1) \right\}.
\]

(viii) \( \xi_1 = \alpha^2, \xi_2 = 0: \) We have \( f(\xi_1, \xi_2) = \max\{f_1(\xi_1, \xi_2), f_2(\xi_1, \xi_2), f_3(\xi_1, \xi_2)\}, \) where \( f_1(\xi_1, \xi_2) = \alpha - \sqrt{\xi_1}, f_2(\xi_1, \xi_2) = \xi_2 \) and \( f_3(\xi_1, \xi_2) = -\xi_2, \) thus

\[
\partial f(\xi_1, \xi_2) = \text{conv} \left\{ \left(-\frac{1}{2\alpha}, 0\right), (0, 1), (0, -1) \right\}.
\]

(ix) When \( \xi_1 > \alpha^2, f(\xi_1, \xi_2) = |\xi_2| = \max\{\xi_2, -\xi_2\}. \) If \( \xi_2 > 0, \) then \( f(\xi_1, \xi_2) = \xi_2, \) so \( \partial f(\xi_1, \xi_2) = \{(0, 1)\}. \) If \( \xi_2 < 0, \) then \( f(\xi_1, \xi_2) = -\xi_2, \) so \( \partial f(\xi_1, \xi_2) = \{(0, -1)\}. \) If \( \xi_2 = 0, \) then \( \partial f(\xi_1, 0) = \text{conv}\{(0, 1), (0, -1)\} = \{0\} \times [-1, 1]. \)
Next, we calculate the Fenchel conjugate of $f$.

In view of (38), run $\partial f$ is closed, so $\text{dom } f^* = \text{ran } f$ by Lemma 8.3. Recall that
\[
 f^*(x_1^*, x_2^*) = x_1 x_1^* + x_2 x_2^* - f(x_1, x_2) \tag{45}
\]
We proceed by cases using (37).

(i) $x_1^* \leq 0$ and $x_2^* = 1$: In this case $x_1 = 0$ and $|x_2| = x_2 \geq \alpha$, hence $f(x_1, x_2) = x_2$. Therefore (45) implies that $f^*(x_1^*, x_2^*) = x_2 - x_2 = 0$.

(ii) $x_1^* \leq 0$ and $x_2^* = -1$: In this case $x_1 = 0$ and $|x_2| = -x_2 \geq \alpha$, hence $f(x_1, x_2) = -x_2$. Therefore (45) implies that $f^*(x_1^*, x_2^*) = -x_2 + x_2 = 0$.

(iii) $-1/(2\alpha) \leq x_1^* \leq 0$ and $|x_2^*| \leq 1 + 2\alpha x_1^*$: In this case, this is exactly the region given by the set $\text{conv } \left\{ (\alpha, 0), (0, 1), (0, -1) \right\} = \partial f(a^2, 0)$. Hence, by (37) we have $(x_1^*, x_2^*) \in \partial f(a^2, 0)$ so that $x_1 = a^2, x_2 = 0$ and $f(x_1, x_2) = 0$. Therefore,
\[
 f^*(x_1^*, x_2^*) = x_1 x_1^* + x_2 x_2^* - f(x_1, x_2) = a^2 \cdot x_1^* + 0 \cdot x_2^* - 0 = a^2 x_1^*. \tag{46}
\]

(iv) $x_1^* < 0$ and $\max\{0, 1 + 2\alpha x_1^*\} \leq x_2^* < 1$: In this case, this is the region given by
\[
 \bigcup \left\{ \text{conv } \left\{ (-1/2x_1^{-1/2}, 0), (0, 1) \right\} : 0 < x_1 < a^2, x_2 = \alpha - x_1^{1/2} \right\} \setminus \{(0, 1)\}.
\]
Then each $(x_1^*, x_2^*) \in \text{conv } \left\{ (-1/2\sqrt{x_1}, 0), (0, 1) \right\}$ for some $(x_1, x_2)$ satisfying $0 < x_1 < a^2, x_2 = \alpha - x_1^{1/2}$. Thus, there exists $\lambda \in ]0, 1]$ such that $x_1^* = -\lambda / \sqrt{x_1}$ and $x_2^* = 1 - \lambda$. Therefore we have $1 / \sqrt{x_1} = -2 / \sqrt{x_1}, \sqrt{x_1} = -1 - x_2^*, x_2 = \alpha - \sqrt{x_1} = \alpha + 1 - x_2^*, f(x_1, x_2) = \alpha - \sqrt{x_1} = x_2$. Now (45) implies that
\[
 f^*(x_1^*, x_2^*) = x_1 x_1^* + x_2 x_2^* - f(x_1, x_2) = (1-x_2^*) x_1^* + (\alpha + 1-x_2^*) x_2^* - (\alpha + 1-x_2^*) x_1^* = (1-x_2^*) x_2^* - (1-x_2^*) x_2^* - \alpha(1-x_2^*) = -x_2^* - \alpha(1-x_2^*).
\]

(v) $x_1^* < 0$ and $-1 < x_2^* \leq \min\{0, -(1+2\alpha x_1^*)\}$: In this case, this is the region given by
\[
 \bigcup \left\{ \text{conv } \left\{ (-1/2x_1^{-1/2}, 0), (0, -1) \right\} : 0 < x_1 < a^2, -x_2 = \alpha - x_1^{1/2} \right\} \setminus \{(0, -1)\}.
\]
Then each \((x_1^*, x_2^*)\) ∈ \(\text{conv}\left\{(-\frac{1}{2\sqrt{x_1}}, 0), (0, -1)\right\}\) for some \((x_1, x_2)\) satisfying \(0 < x_1 < \alpha^2, -x_2 = \alpha - x_1^{1/2}\). As before, let \(\lambda \in [0, 1]\). Then \(x_1^* = -\frac{\lambda}{2\sqrt{x_1}}\) and \(x_2^* = -(1 - \lambda) = \lambda - 1\). Therefore we have \(\frac{1}{\sqrt{x_1}} = -\frac{2}{\lambda} x_1^* = -\frac{2}{1+x_2^2} x_1^*, \sqrt{x_1} = -\frac{1+x_2^2}{2x_1^*}, \)
\(x_2 = -(\alpha - \sqrt{x_1}) = -\alpha - \frac{1+x_2^2}{2x_1^*}\), and \(f(x_1, x_2) = \alpha - \sqrt{x_1} = -x_2\). Now (45) implies that
\[
f^*(x_1^*, x_2^*) = x_1 x_1^* + x_2 x_2^* - f(x_1, x_2)
\]
\[
= \frac{(1+x_2^2)^2}{4x_1^*} x_1^* - (\alpha + \frac{1+x_2^2}{2x_1^*}) x_2^* - (\alpha + \frac{1+x_2^2}{2x_1^*})
\]
\[
= \frac{(1+x_2^2)^2}{4x_1^*} - (\alpha + \frac{1+x_2^2}{2x_1^*}) (x_2^* + 1) = \frac{(1+x_2^2)^2}{4x_1^*} - \frac{(1+x_2^2)^2}{2x_1^*} - \alpha (1 + x_2^*)
\]
\[
= -\frac{(1+x_2^2)^2}{4x_1^*} - \alpha (1 + x_2^*) = -\frac{(1-|x_2^*|^2)}{4x_1^*} - \alpha (1 - |x_2^*|).
\] (47)

\(\Box\) together finish the computation of \(f^*\).

Altogether, the proof is complete.

\section*{II. Proof of Example 7.6}

\textbf{Proof.} We argue by cases.

\textbf{Case 1:} \(x_2 < \alpha - \sqrt{x_1}\) and \(x_1 \geq 0\). We have \(f(x_1, x_2) := \alpha - \sqrt{x_1}\). When \(x_1 > 0\), \(f(x_1, x_2) = \alpha - \sqrt{x_1}\) so \(\partial f(x_1, x_2) = (-1/2x_1^{-1/2}, 0)\); When \(x_1 = 0\) and \(x_2 < \alpha\), \(f(0, x_2) = \alpha, \partial f(x_1, x_2) = \alpha - \sqrt{x_1}\) when \(x_1 > 0\), so \(\partial f(0, x_2) = \varnothing\).

\textbf{Case 2:} \(x_2 > \alpha - \sqrt{x_1}\) and \(x_1 \geq 0\). When \(x_1 > 0\), \(f(x_1, x_2) = x_2\), \(\partial f(x_1, x_2) = \{(0, 1)\}\); When \(x_1 = 0\), \(\partial f(0, x_2) = (0, 1) + \mathbb{R}_- \times \{0\}\).

\textbf{Case 3:} \(x_2 = \alpha - \sqrt{x_1}\). When \(x_1 > 0\), \(\partial f(x_1, x_2) = \text{conv}\{(0, 1), (-1/2x_1^{-1/2}, 0)\}\); When \(x_1 = 0\), \(x_2 = \alpha\), \(\partial f(0, \alpha) = (0, 1) + \mathbb{R}_- \times \{0\}\). \(\Box\)
