Author contributions: All authors were involved in design of experiment; Asgharzadeh F, Mostafapour A, and Khazaei M carried out the experiments and wrote the methods and results sections; Tarnava A and LeBaron TW wrote the background, discussion and conclusion; and all authors agree to final manuscript.

Institutional review board statement: The Mashhad University of Medical Sciences Committee on Animal Ethics has approved all animal protocols used in this research.

Institutional animal care and use committee statement: The Mashhad University of Medical Sciences Committee on Animal Ethics has approved all animal protocols used in this research. Reference Number: 991229; Date: July 10, 2020.

Conflict-of-interest statement: Tarnava A is involved in commercial entities with interest in the marketing of hydrogen-rich water.

Abstract

BACKGROUND
Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the world. Tumor removal remains the preferred frontline treatment; however, effective non-surgical interventions remain a high priority. 5-fluorouracil (5-FU) is a widely used chemotherapy agent, and molecular hydrogen (H₂) has been recognized for its antioxidant and anti-inflammatory effects, with research also suggesting its potential anti-tumor effects. Therefore, H₂ dissolved in water [hydrogen-rich water (HRW)], with or without 5-FU, may present itself as a novel therapeutic for CRC.

AIM
To investigate the effects of HRW, with or without 5-FU, as a novel therapeutic for CRC.
water; LeBaron TW has received travel reimbursement, honoraria, and speaking and consultancy fees from various academic and commercial entities regarding molecular hydrogen. All other authors report no conflict of interest.

Data sharing statement: No additional data are available.

ARRIVE guidelines statement: The authors have read the ARRIVE Guidelines, and the manuscript was prepared and revised according to the ARRIVE Guidelines.

METHODS
CRC was induced in the left flank of inbred Balb/c mice. A total of 24 mice bearing tumors were randomly divided into four groups (n = 6 per group) and treated as follows: (1) Control group; (2) 5-FU group that received intraperitoneal injection of 5-FU (5 mg/kg) every other day; (3) H2 group that received HRW, created and delivered via dissolving the H2-generating tablet in the animals’ drinking water, with 200 μL also delivered by oral gavage; and (4) The combination group, H2 (administered in same way as for group three) combined with 5-FU administered same way as group two.

RESULTS
Administration of HRW + 5-FU significantly improved tumor weight, tumor size, collagen content and fibrosis as compared to the CRC control group. Specifically, HRW attenuated oxidative stress (OS) and potentiated antioxidant activity (AA), whereas 5-FU treatment exacerbated OS and blunted AA. The combination of HRW + 5-FU significantly reduced tumor weight and size, as well as reduced collagen deposition and the degree of fibrosis, while further increasing OS and decreasing AA compared to administration of 5-FU alone.

CONCLUSION
Administration of HRW, with or without 5-FU, may serve as a therapeutic for treating CRC.

Key Words: Colorectal cancer; Molecular hydrogen; 5-fluorouracil; Oxidative stress; Antioxidants; Inflammation

Core Tip: Colorectal cancer is a leading cause of death and is often treated with the chemotherapy drug, 5-fluorouracil (5-FU), which has some unwanted side effects. Molecular hydrogen (H2 gas) has antioxidant, anti-inflammatory, and anti-cancer effects. H2 gas can be dissolved in water to make hydrogen-rich water (HRW). The effects of HRW, 5-FU and the combination of HRW and 5-FU in a colorectal-cancer mouse model were examined. HRW and 5-FU decreased tumor size and weight with the combination being the most effective. In contrast to 5-FU, HRW attenuated oxidative stress and improved antioxidant activity.

INTRODUCTION
Colorectal cancer (CRC) is the third leading cause of cancer-related deaths worldwide, in which statistically 3.2% of men and 2.6% of women will die from the disease[1,2]. CRC has a survival rate of 91% if detected in stage 1. However, its overall 5-year survival rate is only 65%, according to 2020 data from the American Cancer Society published on the SEER database[3]. Surgical removal of rectal cancer remains the first-line treatment of CRC. However, non-surgical treatment options serve as important treatment tools, as rates of screening and surgery approvals between various nations can lead to differences in rate of survival[4].

Molecular hydrogen (H2) has been studied extensively as a therapeutic gas, with an estimated 1500 publications to date exploring its potential therapeutic use in 170 disease models across every organ in the mammalian body. H2 can be administered through several methods, such as H2 inhalation, dissolving H2 gas in water to make hydrogen-rich water (HRW) for oral consumption or topical application, or hydrogen-rich saline.
5-fluorouracil (5-FU) is a widely used chemotherapeutic employed during cancer treatment[5]. H₂ has shown positive effects in terms of quality of life in human clinical research. For example, studies report that H₂ therapy was associated with improved liver function in patients who were administered chemotherapy, as well as reduced side effects for those receiving radiation therapy, and protective effects against radiation-induced bone marrow damage in cancer patients[6-8].

H₂ has been previously demonstrated to display anti-cancer properties when administered on its own. Hyperbaric H₂ therapy has been examined as a potential cancer therapy, revealing potent anti-tumor effects in mice with squamous cell carcinoma[9]. In a study involving mice with colon cancer, it was shown that drinking HRW dose-dependently potentiated the tumor-inhibitory activity of 5-FU by enhancing cellular apoptosis of the cancer cells[10]. In the present study, we aimed to explore the potential effects of a higher concentration of HRW than previously utilized, to further explore the effects of high-concentration HRW compared to control, 5-FU administration on its own, as well as HRW in combination with 5-FU, for the mitigation of CRC progression and accompanying outcomes.

MATERIALS AND METHODS

Chemicals and reagents
HRW was created using H₂-producing tablets (HRW Natural Health Products Inc., New Westminster BC, Canada) by dissolving it in a 500-mL beaker. HRW was made two times each day every 12 h. The concentration of HRW was > 1.5 mmol/L and remained > 0.1 mmol/L after 12 h as determined by redox titration (H2Blue; H2Sciences, Las Vegas, Nevada). 5-FU was obtained from EBEWE Pharma, Unterach, Austria. F12/Dulbecco’s Modified Eagle Medium (DMEM/F12), fetal bovine serum (FBS), penicillin (Pen) and streptomycin (Strep) were obtained from Gibco BRL, Life Technologies Inc. (Gaithersburg, MD, United States).

Cell culture
The mouse colorectal adenocarcinoma cell line CT-26 was obtained from Pasteur Institute (Tehran, Iran). CT-26 cells were cultured in DMEM/F12 medium containing 10% FBS, Pen (50 U/mL) and Strep (50 μg/mL) in a humidified atmosphere containing 5% CO₂ and 95% air at 37 °C.

Xenografts in mice: Treatment and evaluation
Tumor xenograft experiments were conducted as previously described by Golovko et al[11]. In brief, 6- to 8-wk-old female inbred Balb/c mice were injected with 5 × 10⁵ CT-26 cells (100 μL) into the left rear flank (day 0). When tumor volumes reached 80-100 mm³ (-10 d), 24 mice bearing tumors were divided randomly into four groups (n = 6 per group) and treated as follows: (1) The control group; (2) The 5-FU group received intraperitoneal injections of 5-FU (5 mg/kg) every other day; (3) The H₂ group received HRW both from drinking water and by delivering 200 μL of the solution via oral gavage; and (4) The combination group, H₂ (administered in same way as group three) combined with 5-FU (administered in the same way as group two). The tumor volume was calculated every other day according to the following formula: V = (length × width²)/2[12]. The animals were sacrificed on day 14 and the tumors were removed for further analysis.

Histological assay
Fixed tumor tissue samples were embedded in paraffin wax and then sectioned at 5 μm thickness with a microtome. The tumor tissue sections were deparaffinized and stained with Hematoxylin-Eosin for evaluation of tumor necrosis. Masson trichrome staining was also performed for evaluation of collagen content and fibrosis.

Tissue preparation for measurement of oxidative stress markers
The colon tissues samples were homogenized in ice with PBS and centrifuged. The supernatant was stored at -70 °C for the determination of the oxidative and antioxidative proteins.

Malondialdehyde measurement
Malondialdehyde (MDA) was measured by methods as previously described[13]. Briefly, 1 mL of homogenate was mixed with 2 mL of a solution containing thiobar-
bituric acid, trichloroacetic acid, and HCl in hot water (100 °C) for 45 min and centrifuged for ten minutes. The MDA levels were determined by measuring the absorbance of the solution.

**Total thiol group measurement**

We used di-thio nitrobenzoic acid (DTNB) reagent for measurement of total thiol group as previously described[13]. Briefly, 1 mL of Tris-EDTA buffer (pH = 8.6) was added to the colon homogenate and absorbance was measured. Similarly, 20 μL of DTNB reagents was added to the sample absorbance and the absorbance was measured again; subsequently, the total molar concentration of thiol was determined as previously described[14].

**Evaluation of superoxide dismutase and catalase**

Superoxide dismutase (SOD) was determined with a colorimetric assay described by Madesh et al.[15]. The method is centered on the synthesis of SOD by pyrogallol auto-oxidation and inhibition of superoxide-dependent reduction of 3-(4,5-dimethyl-thiazol-2-yl) 2,5-diphenyl tetrazolium bromide (MTT) to its formazan. Catalase was measured by evaluating the kinetics of H₂O₂ hydrolysis at 240 nm in a buffer of sodium phosphate. The velocity of the enzyme activity can be determined by converting H₂O₂ to H₂O and O₂ within 60 s of normal conditions[15].

**Ethics statement**

The Mashhad University of Medical Sciences Committee on Animal Ethics has approved all animal protocols used in this research. Reference Number: 991229; Date: July 10, 2020.

**Data analysis**

The statistical methods of this study were reviewed by Dr. Mohammad Taghi Shakeri, a member of the Biostatistic Department of Mashad University of Medical Sciences. All the results are presented as means and standard error of the mean (mean ± SEM). The differences in the mean values among different groups were determined by a one-way analysis of variance (ANOVA) using the SPSS 22.0 program. Significance was set at values of \(P < 0.05\).

**RESULTS**

**H₂ suppresses tumor growth and enhances the antitumor efficacy of 5-FU in a colon cancer xenograft model**

We studied the influence of H₂ on tumor growth in a CRC xenograft model. Administration of HRW significantly decreased tumor growth in mice (Figure 1). The suppressive effect of HRW on tumor growth was slightly, but not statistically, more potent than 5-FU, and not as effective as the combination therapy. Specifically, the average control tumor size was 2698.85 mm³, whereas the average tumor size in the HRW group was 2047.23 mm³ (24.1% suppression compared to control), while the average tumor size in the 5-FU group was 2097.32 mm³ (22.3% suppression compared to control). The combination group of HRW + 5-FU resulted in the greatest tumor size suppression, with the average size of 1177.5 mm³ (56.4% suppression compared to control) (Figure 1A).

Similarly, a comparison of tumor weight between the groups showed that both 5-FU and HRW significantly reduced tumor weight \((P < 0.05)\), and this decrease was potentiated in the combination group of HRW + 5-FU \((P < 0.001)\) (Figure 1B). Treatment with 5-FU reached statistical significance at day 12 through 14 \((P < 0.05)\) as compared to control, whereas the combination treatment of HRW + 5-FU reached significance by day 6 \((P < 0.05)\) and continued its suppressive effect at day 8 \((P < 0.01)\) and days 10-14 \((P < 0.001)\) compared to control. Moreover, combination treatment was more effective compared to 5-FU treatment alone, reaching significance by day 8 \((P < 0.05)\) with days 10 through 14 being even more significant \((P < 0.01)\).

**The effects of H₂ and 5-FU on redox status**

We investigated the effects of H₂ administered via drinking HRW on levels of markers of OS in tissue homogenates. As shown in Figure 2, HRW treatment decreased MDA levels in tumor tissues compared to control \((P < 0.05)\) and 5-FU treatment \((P < 0.001)\). However, 5-FU treatment increased MDA levels compared to control (Figure 2A, \(P <
Figure 1 Hydrogen, 5-fluorouracil and their combination reduced tumor growth and tumor weight in a murine model of colorectal cancer. A: Tumor size; B: Tumor weight change in mice treated with hydrogen-rich water (HRW), 5-fluorouracil (5-FU) and their combination. \( P < 0.05 \) and \( P < 0.001 \) compared to control, \( P < 0.01 \) compared to 5-FU, \( P < 0.05 \) compared to HRW and \( P < 0.01 \) and \( P < 0.001 \) compared to combination groups; \( n = 6 \) per group. a: \( P < 0.05 \) compare to control; b: \( P < 0.01 \) compare to control; c: \( P < 0.001 \) compare to control; d: \( P < 0.05 \) compare to \( \text{H}_2 \); e: \( P < 0.01 \) compare to 5-FU. \( \text{H}_2 \): Hydrogen; 5-FU: 5-fluorouracil.

Figure 2 Effects of hydrogen and 5-fluorouracil on the oxidative stress index in colorectal cancer. A: Malondialdehyde; B: Total thiol; C: Superoxide dismutase; D: Catalase activity. \( P < 0.05 \), \( P < 0.01 \) and \( P < 0.001 \) compared to control, \( P < 0.05 \) and \( P < 0.001 \) compared to 5-fluorouracil, \( P < 0.001 \) compared to hydrogen groups; \( n = 6 \) per group. a: \( P < 0.05 \) compare to control; b: \( P < 0.01 \) compare to control; c: \( P < 0.001 \) compare to control; d: \( P < 0.05 \) compare to \( \text{H}_2 \); e: \( P < 0.001 \) compare to \( \text{H}_2 \); f: \( P < 0.001 \) compare to 5-FU. \( \text{H}_2 \): Hydrogen; 5-FU: 5-fluorouracil; SOD: Superoxide dismutase; MDA: Malondialdehyde; CAT: Catalase.

HRW tended to improve activity of all three antioxidant markers measured. For example, HRW increased thiol concentrations (Figure 2B) compared to control (\( P < 0.01 \)) and 5-FU treatment (\( P < 0.001 \)). Additionally, we observed a trend towards an increase in SOD and catalase activity following \( \text{H}_2 \) treatment, although significance was only reached when compared to 5-FU treatment. Compared to the control group, there was a significant decrease in levels of all antioxidant markers following 5-FU treatment. In the combination group (HRW and 5-FU), a more prevalent rise in OS and suppression of AA was observed compared to 5-FU alone. MDA levels significantly increased in the combination group compared to control (Figures 2B, 2C and 2D; \( P < 0.001 \)).
0.001) and the 5-FU treatment (P < 0.05). Similarly, activity of all three antioxidants measured were suppressed by the combination compared to control and also when compared to 5-FU alone.

**H₂ and 5-FU increased necrotic areas**

Tumor necrosis was observed under a light microscope. As illustrated in Figures 3A and 3B, treatment of H₂ or 5-FU displayed interspersed tissue necrosis compared to the untreated group. In the H₂ + 5-FU group, we observed larger necrotic areas than the necrotic areas in either group alone.

**H₂ and 5-FU decreased tumor fibrosis in the colon cancer xenograft model**

We used Masson’s trichrome staining to compare the collagen deposition in tumor tissues across the treatment and control groups. Our results demonstrate that administration of either H₂ or 5-FU suppressed collagen deposition and degree of fibrosis compared to the control group (Figure 4A). The increment in percentage of collagen deposition in all treated groups was significantly decreased when compared to the control group (Figure 4B; P < 0.001). Specifically, collagen deposition percentage in the control group was 24.6%. In contrast, with both H₂ and 5-FU alone, the percentage of collagen deposition in the tumor tissue was significantly reduced to about 13% (P < 0.001). However, administration of both H₂ + 5-FU in combination further reduced the percentage of collagen deposition in tumor tissue (≈ 3%) compared to both the 5-FU group and H₂ group (P < 0.001).

**DISCUSSION**

Non-surgical treatment options to improve outcomes in CRC remains a high priority. Ideal adjuvant treatment options should aim to improve quality of life, reduce symptoms, and work synergistically with standard care. Although 5-FU remains the front-line treatment option for a variety of cancers due to its effectiveness, it also has limitations. For instance, cardiotoxicity has shown to be a serious side effect of 5-FU administration, largely due to increases in OS and suppression of endogenous antioxidant mobilization[16]. Accordingly, molecular H₂ has been proposed as a novel approach for the treatment of cardiovascular disorders due to its ability to significantly reduce the effects of OS[17].

Our results demonstrate that the combination of HRW and 5-FU treatment potentiated the beneficial anti-tumor effects of both treatments on their own, such as tumor weight, size, the degree of fibrosis and collagen content in the tumor. Enigmatically, while treatment with HRW on its own significantly improved all three measured antioxidant markers while decreasing levels of MDA, the combination therapy of HRW and 5-FU significantly blunted AA and elevated MDA levels significantly above those measured with 5-FU alone. Acute temporal increases in OS after H₂ administration have been noted in other studies, and it has been previously suggested that molecular H₂ may act as a therapeutic hormetic agent similar to exercise[18-21]. Nogueira et al.[19] (2018) examined the effects of molecular H₂ administration on exercise performance and noted an acute rise in OS in the H₂ treated group, followed by a greater antioxidant mobilization, leading to improved redox homeostasis shortly after the exercise period ended. Further, previously published human clinical research has demonstrated significant improvements in redox homeostasis following medium-term administration of HRW for 24 wk[22]. Since our short-term study was unable to determine the effects of H₂ + 5-FU administration on OS and AA over a longer treatment course, such as has been reported in previous research on HRW[23], future research is warranted to investigate this area.

When administered on its own, HRW demonstrated similar benefits in reducing tumor size compared to 5-FU. These results corroborate earlier reports that HRW can suppress early tumor formation in rats[24]. Additionally, molecular H₂ was shown to prevent tumor progression in a cell line model of lung cancer[25]. In our study, we demonstrated that HRW administration was associated with a significant decrease in pathological collagen content equivalent to that of 5-FU. In contrast to previous reports demonstrating that molecular H₂ upregulates collagen biosynthesis and expression, and corresponding to the results of another study reporting that molecular H₂ significantly reduced type III collagen depositions as observed via staining[26-28]. Molecular H₂ has shown to both be able to promote and suppress outcomes, model dependent, for many biological processes, which may indicate that contradictory reports do not undermine our understanding of the mechanisms by which H₂
Figure 3 Hydrogen and 5-fluorouracil induce necrosis in tumor tissue of colorectal cancer. A: Trichrome staining of tumor samples revealed that hydrogen (H\(_2\)) suppresses fibrosis in the murine model of colorectal cancer (collagen fiber accumulation appears in blue); B: Tumor fibrosis expressed as collagen content (%) in different groups. \(P < 0.001\) compared to control, \(P < 0.001\) compared to 5-fluorouracil, \(P < 0.01\) compared to \(H_2\) groups; \(n = 6\) per group. a: \(P < 0.001\) compare to control; b: \(P < 0.001\) compare to 5-FU; c: \(P < 0.001\) compare to \(H_2\); \(H_2\): Hydrogen; 5-FU: 5-fluorouracil.

operates. HRW demonstrated similar outcomes to 5-FU for visual results of fibrosis from mass trichrome staining. Further, molecular \(H_2\) has been previously demonstrated to reduce fibrosis in the lungs and abdomen[29,30].

Interestingly, the combination of 5-FU and HRW demonstrated significant reductions of tumor weight, size, collagen deposition and degree of fibrosis, while increasing markers of OS and blunting AA significantly beyond 5-FU alone. Previous studies have demonstrated that HRW generally reduces OS in most animal and human disease models when administered as a stand-alone intervention. Molecular \(H_2\) has been observed to work in an additive or synergistic capacity with several other interventions in various models, as demonstrated by a recent study, in which administration of high-concentration HRW alongside minocycline improved outcomes following ischemic stroke in rats[31]. Additionally, molecular \(H_2\) has shown to enhance the effects of photothermal therapy by inhibiting tumor progression in cell cultures and was also shown to act equivalently to sulfasalazine in a dextran sodium sulfate-induced mouse model of colitis, with the combination therapy of HRW + sulfasalazine demonstrating effects of significantly greater magnitude than either treatment on its own[32,33].

Treatment with 5-FU has been shown to result in DNA damage[34]. Alterations in various processes, such as nucleotide and amino acid metabolism, may lead to 5-FU resistance[35]. Autophagy plays an important role in nucleotide and amino acid metabolism, and \(H_2\) has been shown to both stimulate and mitigate autophagy for beneficial outcomes[36-40]. It has also been suggested that therapies which mediate DNA repair alongside 5-FU and other cancer treatments should be further explored as a therapeutic target[41]. For instance, it has been shown that \(H_2\) exerted significant protective effects against DNA damage in calf thymus tissue following exposure to radiation[42]. Future research is also needed in order to address both potential protective effects and long-term benefits of molecular \(H_2\) delivered in conjunction with 5-FU and other conventional cancer therapies, exploring outcomes related to DNA damage, cell signaling, and survival rates.
So far, little is known regarding the effects of various dosages and different administration methods of HRW, H\textsubscript{2} inhalation, and hydrogen-rich saline on cancer cells. To date, several routes have shown potential benefits of HRW administration for cancer treatment, including the previously cited reports using inhalation studies in humans, and HRW use in murine models. Additionally, a recent report demonstrated that the use of H\textsubscript{2}-producing reactive magnesium implants was associated with significant suppression of tumor growth in a mouse model of ovarian cancer\textsuperscript{43}. However, since H\textsubscript{2} has demonstrated protective effects on healthy cells, it could also protect and stimulate cancer cell growth. For example, H\textsubscript{2} administration has been demonstrated to induce the mitochondrial unfolded protein response, which is also a proliferative signal in various cancer cells\textsuperscript{44,45}. Therefore, the effects of different dosages and administration methods of molecular H\textsubscript{2} should be carefully analyzed to determine its effects.

**CONCLUSION**

Safe and well-tolerated adjuvant therapeutics with the potential to ameliorate the deleterious consequences of various cancer treatments, while simultaneously improving outcomes, are of high interest to cancer patients and the medical community. Molecular H\textsubscript{2} therapy demonstrates potential anti-cancer properties, as well as the ability to reduce the secondary effects of various treatments. In this study, we have shown that administered on its own, HRW demonstrates anti-cancer properties and improves markers of OS and AA compared to conventional treatment (5-FU). The combination of HRW and 5-FU suppressed tumor progression in a synergistic manner; however, the addition of HRW to 5-FU treatment increased OS levels and reduced AA. Limitations of this study include that the observation period during the study was only 14 d, with rates of survival and remission not examined. As such, interpretation of these results should be evaluated cautiously. Larger, longer-term studies are highly warranted to explore HRW as an adjuvant therapy for various cancers, alongside conventional therapy, with longer observational periods needed to address unanswered questions regarding potential positive and negative effects of molecular H\textsubscript{2} on redox homeostasis during cancer treatment.

**ARTICLE HIGHLIGHTS**

Research background

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths worldwide. Surgical removal remains the first-line treatment for CRC; however, nonsurgical options remain important tools for treatment. Currently, treatments such as 5-fluorouracil (5-FU), a widely administered chemotherapeutic agent utilized in the treatment of CRC, presents known beneficial effects, but also significant side effects. Hydrogen-rich water (HRW) has demonstrated beneficial effects in numerous species, including humans, in many disease models, including various cancers. One attractive aspect of HRW is the high safety profile and low rates of side effects combined with its promising therapeutic effects.

Research motivation

New treatments with potential positive effects in CRC are desperately needed, particularly treatments with high safety profiles and low side effects. HRW may fit the criteria as a safe potential treatment for CRC, either as a stand-alone treatment or in combination with conventional treatments.

Research objectives

We aimed to evaluate the efficacy of HRW on a CRC model compared to 5-FU and control, as well as the combination treatment of HRW and 5-FU compared to 5-FU alone, HRW alone, or control. We measured tumor size, tumor weight, fibrosis, and collagen content, as well as oxidative stress (OS) and antioxidant activity (AA) in mice with induced CRC. These objectives allow us to determine the therapeutic efficacy and mechanistic insight of HRW with or without 5-FU, as well as determine if there are additive benefits in a combinational treatment to guide future clinical studies.
Research methods
Six- to eight-week-old female inbred Balb/c mice were injected with 5 × 10^5 CT-26 cells (100 μL) into the left rear flank (day 0). When tumor volumes reached 80-100 mm^3, 24 mice bearing tumors were randomly divided into four groups. Mice were either left untreated (control) or treated with 5-FU (intraperitoneal injection, 5 mg/kg every other day), high-concentration HRW produced by magnesium tablets (ad libitum in drinking water, as well as by oral gavage 200 μL daily), or both HRW and 5-FU.

Research results
We report that molecular hydrogen dissolved in water (HRW) was as effective as 5-FU, with more preferential outcomes relating to higher AA and lower OS. Importantly, the combination of HRW and 5-FU was superior to either therapy on its own, presenting the possibility that HRW may be explored as an adjuvant therapy alongside conventional chemotherapeutics.

Research conclusions
HRW may be a novel safe adjuvant therapy for treating CRC, either as a stand-alone therapy, or preferably, alongside conventional chemotherapeutics.

Research perspectives
Clinical research to evaluate the effects of HRW as a treatment for CRC, both alone and in combination with 5-FU and other chemotherapeutics, is highly warranted.

ACKNOWLEDGEMENTS
We thank Mr. Alex Tarnava, CEO of HRW Natural Health Products Inc. for kindly donating Drink HRW tablets for this study and Mashhad University of Medical Sciences for their support.
