I. INTRODUCTION

Consider the signal recovery problem for the following linear model:

\[ y = Ax + n, \tag{1a} \]

\[ x_j \sim P_X(x), \ \forall j, \tag{1b} \]

where \( A \in \mathbb{R}^{M \times N} \) is a channel matrix (for communication applications) or a sensing matrix (for compressed sensing), \( x \in \mathbb{R}^{N \times 1} \) the signal to be recovered, \( n \in \mathbb{R}^{M \times 1} \) a vector of additive white Gaussian noise (AWGN) samples with zero mean and variance \( \sigma^2 \), and \( P_X(x) \) a probability distribution with \( E[x_j] = 0 \) and \( E[x_j^2] = 1 \). We assume that \( \{x_j\} \) are independent identically distributed (IID). Our focus is on systems with large \( M \) and \( N \).

Except when \( P_X(x) \) is Gaussian or for very small \( M \) and \( N \), finding the optimal solution to (1) (under, e.g., the minimum mean-squared error (MMSE) criterion [1]) can be computationally prohibitive. Approximate message passing (AMP) [2] offers a computationally tractable option. AMP involves the iteration between two modules: one for linear estimation (LE) based on (1a) and the other for symbol-by-symbol non-linear estimation (NLE) based on (1b). An Onsager term is introduced to regulate the correlation problem during iterative processing.

When \( A \) contains zero-mean IID Gaussian (or sub-Gaussian) entries, the dynamical behavior of AMP can be characterized by a simple scalar recursion, referred to as state evolution (SE) [2]–[4]. The latter bears similarity to density evolution [5] (including EXIT analysis [6]) for message passing decoding algorithms. However, the underlying assumptions are different: density evolution requires sparsity in \( A \) [5] while SE does not [3]. When \( A \) is IID Gaussian, it is shown in [7] that the fixed-point equation of the SE for AMP coincides with that of the MMSE performance for a large system. (The latter can be obtained using the replica method [8]–[11].) This implies that, when \( A \) is IID Gaussian, AMP is Bayes-optimal provided that the fixed-point of SE is unique.

The SE framework of AMP works with any \( P_X(x) \). Such \( P_X(x) \) can be the distribution of, e.g., amplitude or phase modulation that is widely used in signal transmission. For this reason, AMP is also suitable for communication applications such as massive MIMO detection [12], [13] and millimeter wave channel estimation [14] (in which \( A \) represents a channel matrix). AMP has also been investigated for decoding sparse regression codes [15], [16], which have theoretically capacity approaching performances.

The IID assumption for \( A \) is crucial to the SE of AMP [3], [4]. When \( A \) is not IID (especially when \( A \) is...
ill-conditioned), the accuracy of SE is not warranted and AMP may perform poorly [17]. Various algorithms have been proposed to handle more general matrices [17]–[23], but most of the existing algorithms lack accurate SE characterization. An exception is the work in [24], which considers a closely related problem and uses a method different from this paper.

The work in this paper is motivated by our observation that, the SE for AMP is still relatively reliable for a wider family of matrices other than IID Gaussian ones when the OAMP term is small. Our contributions are summarized below.

- We propose a modified AMP algorithm consisting of a de-correlated LE and a divergence-free NLE. The proposed algorithm allows LE structures beyond MF, such as pseudo-inverse (PINV) and linear MMSE (LMMSE). OAMP extends and provides new interpretations of our previous work in [26] and [27].
- We derive an SE procedure for OAMP, which is accurate if the errors are independent during the iterative process. Independency, however, is a tricky condition. We will show that the use of a de-correlated LE and a divergence-free NLE makes the errors statistically orthogonal, hence the name orthogonal AMP (OAMP). Intuitively, such orthogonality partially satisfies the independency requirement. Our numerical results indicate that the SE predictions are reliable for various matrix ensembles (e.g., IID Gaussian, partial orthogonal and some ill-conditioned ones for which AMP does not work well) and also for various LE structures as mentioned above. Thus OAMP may have wider applications than AMP.
- We derive optimal choices within the OAMP framework. We find that the fixed-point characterization of the SE is consistent with that of the optimal MMSE performance obtained by the replica method. This implies the potential optimality of OAMP. Compared with AMP, our result holds for the more general unitarily-invariant matrix ensemble.

We will provide numerical results to show that, compared with AMP, OAMP can achieve better MSE performance as well as faster convergence speed for ill-conditioned matrices. We will demonstrate the excellent performance of OAMP in communication systems with non-sparse binary phase shift keying (BPSK) signals as well as conventional sparse signals.

After we posted the preprint of this work [28], proofs were previous work in [26] and [27].

Part of the results in this paper have been published in [30]. In this paper, we provide more detailed analysis and numerical results.

Notations: Boldface lowercase letters represent vectors and boldface uppercase symbols denote matrices. \( \mathbf{0} \) for a matrix or a vector with all-zero entries, \( \mathbf{I} \) for the identity matrix with a proper size, \( a^\dagger \) for the conjugate of \( a \), \( \| a \| \) for the \( \ell_2 \)-norm of the vector \( a \), \( \text{tr}(A) \) for the trace of \( A \), \( (\eta(a))_j \equiv \eta(a_j) \cdot \text{diag}[A] \) for the diagonal part of \( A \), \( \mathcal{N}(\mu, C) \) for Gaussian distribution with mean \( \mu \) and covariance \( C \), \( E(\cdot) \) for the expectation operation over all random variables involved in the brackets, except when otherwise specified. \( E(a|b) \) for the expectation of \( a \) conditional on \( b \), \( \text{var}[a] \) for \( E \{ (a - E[a])^2 \} \), \( \text{var}[a|b] \) for \( E \{ (a - E[a|b])^2 | b \} \).

B. STATE EVOLUTION FOR AMP

Define
\[
q^t \equiv s^t - x \quad \text{and} \quad h^t \equiv r^t - x.
\]

After some manipulations, (2) can be rewritten as [3, eq. (3.3)] (with initialization \( q^0 = -x \) and \( h^0_{\text{Onsager}} = \mathbf{0} \)):

\[
\text{LE:} \quad h^t = (\mathbf{I} - A^T A) q^t + A^T n + h^t_{\text{Onsager}},
\]

\[
\text{NLE:} \quad q^{t+1} = \eta_t (x + h^t) - x, \quad (4b)
\]

where
\[
h^t_{\text{Onsager}} = \frac{N}{M} \left( \frac{1}{N} \sum_{j=1}^N \eta_{j-1} \left( x_j + h^j_{\text{Onsager}} \right) \right) \cdot (h^{t-1} - q^{t-1}).
\]

Strictly speaking, (4) is not an algorithm since it involves \( x \) that is to be estimated. Nevertheless, (4) is convenient for the analysis of AMP discussed below.

The SE for AMP refers to the following recursion:

\[
\text{LE:} \quad \tau_t^2 = \frac{N}{M} v_t^2 + \sigma^2,
\]

\[
\text{NLE:} \quad v_{t+1}^2 = E \left( \left[ \eta_t (X + \tau_t Z) - X \right]^2 \right),
\]

where \( Z \sim \mathcal{N}(0,1) \) is independent of \( X \sim P_X(x) \), and \( v_0^2 = E[X^2] \).

The formulation here is different to the standard form in [2], but they can be shown to be equivalent.
When \( A \) has IID Gaussian entries, SE can accurately characterize AMP, as shown in [3, Th. 1] below.

**Theorem 1 [3, Th. 2]:** Let \( \psi: \mathbb{R}^2 \mapsto \mathbb{R} \) be a pseudo-Lipschitz function.\(^3\) For each iteration, the following holds almost surely when \( M, N \to \infty \) with a fixed ratio

\[
\frac{1}{N} \sum_{j=1}^{N} \psi \left( h_j^t, x_j \right) \rightarrow \mathbb{E} \left\{ \psi \left( \tau_t Z, X \right) \right\},
\]

(6)

where \( \tau_t \) is given in (5).

To see the implication of Theorem 1, let \( \psi(h, x) \equiv [\eta_t(x + h) - x]^2 \) in (6). Then, Theorem 1 says that the empirical mean square error (MSE) of AMP defined by

\[
\frac{1}{N} \| \eta_t (x + h^t) - x \|^2
\]

(7)

converges to the predicted MSE (where \( \tau_t \) is obtained using SE) defined by

\[
\mathbb{E} \left\{ [\eta_t (X + \tau_t Z) - X]^2 \right\}.
\]

(8)

**C. LIMITATION OF AMP**

The assumption that \( A \) contains IID entries is crucial to theorem 1. For other matrix ensembles, SE may become inaccurate. Here is an example. Consider the following function for the NLE in AMP\(^4\)

\[
\eta_t (r^t) = \tilde{\eta}_t (r^t) - (1 - \beta) \cdot \left( \frac{1}{N} \sum_{j=1}^{N} \tilde{\eta}_t (r_j^t) \right) \cdot r^t,
\]

(9)

where \( \tilde{\eta}_t \) is the thresholding function (which is commonly used in sparse signal recovery algorithms [31]) given in (47) with \( \gamma_t = 1 \). A family of \( \eta_t \) is obtained by changing \( \beta \). In particular, \( \eta_t \) reduces to the soft-thresholding function \( \hat{\eta}_t \) when \( \beta = 1 \). We define a measure of the SE accuracy (after a sufficient number of iterations) as

\[
\mathbb{E} \equiv \frac{|\text{MSE}_{\text{sim}} - \text{MSE}_{\text{SE}}|}{\text{MSE}_{\text{sim}}},
\]

(10)

where \( \text{MSE}_{\text{sim}} \) and \( \text{MSE}_{\text{SE}} \) are the simulated and predicted MSEs in (7) and (8). Here, as the empirical MSE is still random for large but finite \( M \) and \( N \), we average it over multiple realizations.

By changing \( \beta \) from 0 to 1, we obtain a family of \( \eta_t \). The solid line in Fig. 1 shows \( E \) defined in (10) against \( \beta \) for \( A \) being IID Gaussian. We can see that SE is quite accurate in the whole range of \( \beta \) shown (with \( E < 10^{-2} \)), which is consistent with the result in Theorem 1.

However, as shown by the dashed line, SE is not reliable when \( A \) is a partial DCT matrix. The partial DCT matrix

\[
\text{is obtained by uniformly randomly selecting the rows of a discrete cosine transform (DCT) matrix, and it is widely used in compressed sensing. To see the problem, let us ignore the Onsager term. Suppose that } q' \text{ consists of IID entries with } \mathbb{E}\{|q'_j|^2\} = \nu_j^2, \text{ and } q' \text{ is independent of } A \text{ and } n. \text{ It can be verified that}
\]

\[
\tau_t \equiv \frac{1}{N} \mathbb{E}\{||h^t||^2\} = \frac{N - M}{M} \cdot \nu_j^2 + \sigma^2.
\]

Clearly, this is inconsistent with the SE in (5a). The problem is caused by the discrepancy in eigenvalue distributions: (11) above is derived from the eigenvalue distribution of a partial DCT matrix while (5a) from that of an IID Gaussian \( A \).

How about replacing (5a) by (11) for the partial DCT matrix? This is shown by the solid line with triangle markers in Fig. 1. We can see that \( E \) is still large for \( \beta > 0 \), which can be explained by the fact the Onsager term was ignored above. Interestingly, we can see that \( E \) is very small at \( \beta = 0 \), where the Onsager term vanishes for the related \( \eta_t \) in (9). This observation motivates the work presented below.

**III. ORTHOGONAL AMP**

In this section, we first introduce the concepts for de-correlated and divergence-free structures for the LE and NLE. We then discuss the OAMP algorithm and its properties.

**A. DE-CORRELATED LINEAR ESTIMATOR**

Return to (1a): \( y = Ax + n \). Let \( s \) be an estimate of \( x \). Assume that \( s \) has IID entries with \( \mathbb{E}(s_j - x_j)^2 = \sigma^2 \). Consider the linear estimation (LE) structure below [1] for \( x \)

\[
r = s + W(y - As),
\]

(12)

which is specified by \( W \). Let the singular value decomposition (SVD) of \( A \) be \( A = USU^\top \). Throughout this paper,
we will focus on the following structure for $W$

$$W = UGV^T.$$  \hfill (13)

**Definition 1 (Unitarily-Invariant Matrix):** $A = V\Sigma U^T$ is said unitarily-invariant \cite{32} if $U$, $V$ and $\Sigma$ are mutually independent, and $U$, $V$ are Haar-distributed (i.e., isotropically random).\textsuperscript{5}

Assume that $A$ is unitarily-invariant. We will say that the LE (or $W$ in (13)) is a de-correlated one if $\text{tr}(I - WA) = 0$. Given an arbitrary $W$ that satisfies (13), we can construct $W$ with $\text{tr}(I - WA) = 0$ as follows

$$W = \frac{N}{\text{tr}(WA)}\hat{W}.$$ \hfill (14)

The following are some common examples \cite{1} of such $\hat{W}$ matched filter (MF):

$$\hat{W}^\text{MF} = A^T,$$ \hfill (15a)

pseudo-inverse (PINV)\textsuperscript{6}:

$$\hat{W}^\text{PINV} = \begin{cases} A^T(\text{AA}^T)^{-1} & \text{if } M < N \\ (A^TA)^{-1}A^T & \text{if } M > N, \end{cases}$$ \hfill (15b)

linear MMSE (LMMSE):

$$\hat{W}^\text{LMMSE} = v^2A^T(v^2AA^T + \sigma^2I)^{-1}. \hfill (15c)$$

We will discuss the properties of de-correlated LE in Section III-F later.

### B. DIVERGENCE-FREE ESTIMATOR

Consider signal estimation from an observation corrupted by additive Gaussian noise

$$R = X + \tau Z,$$ \hfill (16)

where $X \sim P_X(x)$ is the signal to be estimated and is independent of $Z \sim \mathcal{N}(0, 1)$. For this additive Gaussian noise model, we define divergence-free estimator (or a divergence-free function of $R$) as follows.

**Definition 2 (Divergence-Free Estimator):** We say $\eta$: $\mathbb{R} \mapsto \mathbb{R}$ is divergence-free (DF) if

$$E\left[\eta'(R)\right] = 0.$$ \hfill (17)

A divergence-free function $\eta$ can be constructed as

$$\eta(r) = C \left(\eta'(r) - E\left[\eta'(R)\right]\right) r,$$ \hfill (18)

where $\hat{\eta}$ is an arbitrary function and $C$ an arbitrary constant.

### C. OAMP ALGORITHM

Starting with $s^0 = 0$, OAMP proceeds as

**LE:**

$$r' = s' + W_t(y - As^t). \hfill (19a)$$

**NLE:**

$$s^{t+1} = \eta_t(r'). \hfill (19b)$$

where $W_t$ is de-correlated and $\eta_t$ is divergence-free. In the final stage, the output is

$$\left(s^{t+1}\right)_{\text{out}} = \eta_t^\text{out}(r'). \hfill (20)$$

where $\eta_t^\text{out}$ is not necessarily divergence-free.

OAMP is different from the standard AMP in the following aspects:

- In (19a), $W_t$ is restricted to be de-correlated, but it still has more choices than its counterpart $A^T$ in (2a).\textsuperscript{7}

- In (19a), the function $\eta_t$ is restricted to be divergence-free. Consequently, the Onsager term vanishes.

- A different estimation function $\eta^\text{out}_t$ (not necessarily divergence-free) is used to produce a final estimate.

We will show that, under certain assumptions, restricting $W_t$ to be de-correlated and $\eta_t$ to be divergence-free ensures the orthogonality between the input and output “error” terms for both LE and NLE. The name “orthogonal AMP” comes from this fact.

### D. OAMP ERROR RECURSION AND SE

Similar to (3), define the error terms as $h' = r' - x$ and $q' = s' - x$. We can write an error recursion for OAMP (similar to that for AMP in (4)) as

**LE:**

$$h' = B_t q' + W_t n,$$ \hfill (21a)

**NLE:**

$$q^{t+1} = \eta_t(x + h'') - x,$$ \hfill (21b)

where $B_t = I - W_t A$. Two error measures are introduced:

$$\tau_t^2 \equiv \frac{1}{N} \cdot E \left[\|h''\|^2\right], \hfill (22a)$$

$$v_{r+1}^2 \equiv \frac{1}{N} \cdot E \left[\|q^{t+1}\|^2\right]. \hfill (22b)$$

The SE for OAMP is defined by the following recursion

**LE:**

$$\tau_t^2 = \frac{1}{N} \cdot E \left[\text{tr}(B_t B_t^T)\right] v_t^2 + \frac{1}{N} \cdot E \left[\text{tr}(W_t W_t^T)\right] \sigma^2,$$ \hfill (23a)

**NLE:**

$$v_{r+1}^2 = E \left[\eta_t(x + \tau_t Z) - X\right]^2,$$ \hfill (23b)

where $X \sim P_X(x)$ is independent of $Z \sim \mathcal{N}(0, 1)$. Also, at the final stage, the MSE is predicted as

$$E \left[\eta_t^\text{out}(X + \tau_t Z) - X\right]^2.$$ \hfill (24)

### E. RATIONALES FOR OAMP

It is straightforward to verify that the SE in (23) is consistent with the error recursion in (21), provided that the following two assumptions hold for every $t$.

**Assumption 1:** $h'$ in (21a) consists of IID zero-mean Gaussian entries independent of $x$.

**Assumption 2:** $q^{t+1}$ in (21b) consists of IID entries independent of $A$ and $n$.\textsuperscript{7}

---

\textsuperscript{5}It turns out that the distribution of $V$ does not affect the average performance of OAMP. The reason is that OAMP implicitly estimates $x$ based on $V^Ty$, and $V^Tn$ has the same distribution as $n$ for an arbitrary orthogonal matrix $V$ due to the unitary-invariance of Gaussian distribution \cite{32}.

\textsuperscript{6}We assume that $A$ has full rank.

\textsuperscript{7}When the entries of $A$ are IID with zero mean and variance $1/M$ (as considered in \cite{2}), $N/\text{tr}(A^TA) \approx 1$, and so $W_t = A^T$ satisfies the condition in (13) and (14).
According to our earlier assumption below (1), $x$ is IID and independent of $A$ and $n$. In OAMP, $q_{t}^{0} = -x$, so Assumption 2 holds for $t = -1$. Thus the two Assumptions will hold if we can prove that they imply each other in the iterative process. Unfortunately, so far, we cannot.

Assumptions 1 and 2 are only sufficient conditions for the SE. Even if they do not hold exactly, the SE may still be valid. In Section V, we will show that the SE for OAMP is accurate for a wide range of sensing matrices using simulation results. In the following two subsections, we will see that, with a de-correlated $W_t$ and a divergence-free $\eta_t$, Assumptions 1 and 2 can partially imply each other. We emphasize that the discussions below are to provide intuition for OAMP, which are by no means rigorous.

**F. INTUITIONS FOR THE LE STRUCTURE**

Eqn. (19a) performs linear estimation of $x$ from $y$ based on Assumption 2 (for $q_{t}^{'}$). We first consider ensuring Assumption 1 based on Assumption 2. The independence requirements in Assumption 1 are difficult to handle. We reduce our goal to remove the correlation among the variables involved. This is achieved by restricting $W_t$ to be de-correlated, as shown below. 

Proposition 1: Suppose that Assumption 2 holds and $A$ is unitarily-invariant. If $W_t$ is de-correlated, then the entries of $h_t^{'}$ are uncorrelated with those of $x$. Furthermore, the entries of $h_t^{'}$ in (21a) are mutually uncorrelated with zero-mean and identical variances.

Proof: See Appendix A.

Some comments are in order.

(i) The name “de-correlated” LE comes from Proposition 1.

(ii) Under the same conditions as Proposition 1, the input and output error vectors for LE are uncorrelated, namely, $E\{h_t^{'} (q_t^{'})^T\} = 0$.

(iii) A key condition to Proposition 1 is that the sensing matrix $A$ is unitarily invariant. Examples of such $A$ include the IID Gaussian matrix ensemble and the partial orthogonal ensemble [10]. Note that there is no restriction on the eigenvalues of $A$. Thus, OAMP is potentially applicable to a wider range of $A$ than AMP.

(iv) We can meet the de-correlated constraint using (14), in which $W_t$ can be chosen from those in (15). Thus OAMP has more choices for the LE than AMP, which makes the former potentially more efficient.

**G. INTUITIONS FOR THE NLE STRUCTURE**

We next consider ensuring Assumption 2 based on Assumption 1. From (21), if $q_t^{i+1}$ is independent of $h_t^{'}$, then it is also independent of $A$ and $n$, which can be seen from the Markov chain $A, n \rightarrow h_t^{'} \rightarrow q_t^{i+1}$. Thus it is sufficient to ensure the independency between $q_t^{i+1}$ and $h_t^{'}$. Similar to the discussion in Section III-F, we reduce our goal to ensuring orthogonality between $q_t^{i+1}$ and $h_t^{'}$.

Suppose that Assumption 1 holds, we can construct an approximate divergence-free function $\eta_t$ according to (18):

$$\eta_t (r_t) = C_t \cdot (\hat{n}_t (r_t) - \frac{1}{N} \sum_{j=1}^{N} \hat{n}_t (r_t^j)) \cdot r_t.$$  \hspace{1cm} (25)

All the numerical results about OAMP shown in Section V are based on (19) and (25).

There is an inherent orthogonality property associated with divergence-free functions.

**Proposition 2:** If $\eta$ is a divergence-free function, then 

$$E\{\tau_t Z_t \cdot \eta_t (X + \tau_t Z_t)\} = 0.$$  \hspace{1cm} (26)

Proof: From Stein’s Lemma [3], [33], we have

$$E\{Z \cdot \varphi (Z)\} = E\{\varphi' (Z)\}.$$ \hspace{1cm} (27)

for any $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ such that the expectations in (27) exist. Applying Stein’s lemma in (27) with $\varphi (Z) \equiv \eta_t (X + \tau_t Z_t)$, we have

$$E\{\tau_t Z_t \cdot \eta_t (X + \tau_t Z_t)\} = \tau_t E\{Z_t \cdot \eta_t (X + \tau_t Z_t)\}$$ \hspace{1cm} (28a)

$$= \tau_t E\{Z_t \cdot \eta_t (X + \tau_t Z_t)\}$$ \hspace{1cm} (28b)

$$= \tau_t^2 E\{\eta_t (X + \tau_t Z_t)\}$$ \hspace{1cm} (28c)

$$= \tau_t^2 E\{\eta_t (X + \tau_t Z_t)\},$$ \hspace{1cm} (28d)

where $\eta_t (X + \tau_t Z_t) \equiv \eta_t (R_t) \mid R_t = X + \tau_t Z_t$. Combining (28) with Definition 2, we arrive at (26).

Noting that $E\{Z X\} = 0$, (26) is equivalent to

$$E\{(R'_t - X) \cdot [\eta_t (R'_t) - X]\} = 0,$$  \hspace{1cm} (29)

where $R'_t \equiv X + \tau_t Z_t$. In (29), $R'_t - X$ and $\eta_t (R'_t) - X$ represent, respectively, the error terms before and after the estimation. Eqn. (29) indicates that these two error terms are orthogonal. (They are also uncorrelated as $R'_t - X$ has zero mean.) Thus the divergence-free constrain on the NLE is to establish orthogonality between $q_t^{i+1}$ and $h_t^{'}$.

**H. BRIEF SUMMARY**

If the input and output errors of the LE and NLE are independent of each other, Assumptions 1 and 2 naturally hold. However, independency is generally a tricky issue. We thus turn to orthogonality instead. The name “orthogonal AMP” comes from this fact. Propositions 1 and 2 are weaker than Assumptions 1 and 2. Nevertheless, our extensive numerical study (see Section V) indicates that the SE in (23) is indeed reliable for OAMP.

Also note that each of Propositions 1 and 2 depends on one assumption, so they do not ensure orthogonality in the overall process. Nevertheless, we observed from numerical results that the orthogonality property is accurate for with unitarily-invariant matrices.
I. MSE ESTIMATION

The MSEs \( v_T^2 = E[\|q_t\|^2]/N \) and \( \tau^2_t = E[\|h_t\|^2]/N \) can be used as parameters of \( \tilde{W}_t \) and \( \eta_t \). An example is the optimized \( \tilde{W}_t \) and \( \eta_t \) given in Lemma 1 in Section IV. We now discuss empirical estimators for \( v_T^2 \) and \( \tau^2_t \).

We can adopt the following estimator [34, eq. (71)] for \( v_T^2 \)

\[
\hat{v}_T^2 = \frac{\|y - A\hat{\lambda}^2 - M \cdot \sigma^2}{\text{tr}(A^T A)}. \tag{30}
\]

Note that \( \hat{v}_T^2 \) in (30) can be negative. We may use max(\( \hat{v}_T^2 \), \( \epsilon \)) as a practical estimator for \( v_T^2 \), where \( \epsilon \) is a small positive constant. (Setting \( \epsilon = 0 \) may cause a stability problem.)

Given \( \hat{v}_T^2 \), \( \tau^2_t \) can be estimated using (23a):

\[
\hat{\tau}_t^2 = \frac{1}{N} \text{tr}(B_t B_t^T) \cdot \hat{v}_T^2 + \frac{1}{N} \text{tr}(W_t W_t^T) \cdot \sigma^2. \tag{31}
\]

In certain cases, Eqn. (31) can be simplified to more concise formulas. For example, (31) simplifies to \( \hat{\tau}_t^2 = (N - M)/M \cdot \hat{v}_T^2 + N/M^2 \cdot \text{tr}\left(\left(AA^T\right)^{-1}\right) \cdot \sigma^2 \) when \( \tilde{W}_t \) is given by the PINV estimator in (15b) together with (14). Also, simple closed-form asymptotic expression exists for (31) for certain matrix ensembles. For example, (23a) converges to (42a), (42b) and (42c) for IID Gaussian matrices with MF, PINV and LMMSE linear estimators, respectively.

The numerical results presented in Section V are obtained based on approximations in (30) and (31).

IV. OPTIMAL STRUCTURES FOR OAMP

In this section, we derive the optimal LE and NLE structures for OAMP based on SE. We show that OAMP can potentially achieve optimal performance, provided that its SE is reliable.

A. ASYMPTOTIC EXPRESSION FOR SE

Recall that \( A = V \Sigma U^T \) and \( B = I - W_t A \). From (13) and (14), we have \( \tilde{W}_t = N / \text{tr}(W_t A) \cdot \hat{W}_t \) and \( \hat{W}_t = U \hat{G}_t V^T \). With these definitions, we can rewrite the right hand side of (23a) as follows

\[
\Phi_t(v_T^2) \equiv \left( \frac{1}{N} \sum_{i=1}^{N} g_i^2 \hat{\lambda}_i^2 \right) v_T^2 - 1 \left( \frac{1}{N} \sum_{i=1}^{N} \hat{g}_i \hat{\lambda}_i \right) + \left( \frac{1}{N} \sum_{i=1}^{N} g_i^2 \hat{\lambda}_i^2 \right) \sigma^2, \tag{32}
\]

where \( \lambda_i \) and \( \hat{g}_i \) denote the \( i \)-th diagonal entries of \( \Sigma (M \times N) \) and \( \hat{G}_t (N \times M) \), respectively. In (32), we define \( \lambda_i = \hat{g}_i = 0 \) for \( i = M + 1, \ldots, N \).

In (32), \( \Phi_t(v_T^2) \) is for fixed \( \lambda_i \) and \( \{\hat{g}_i\} \). Now, following [35], assume that the empirical cumulative distribution function (cdf) of \( \{\lambda_1^2, \ldots, \lambda_N^2\} \), denoted by

\[
\hat{F}_{\lambda} \lambda_A (\lambda) = \frac{1}{N} \sum_{i=1}^{N} \mathbb{I}(\lambda_i^2 \leq \lambda^2)
\]

converges to a limiting distribution when \( M, N \to \infty \) with a fixed ratio. Furthermore, assume that \( \hat{g}_i \) can be generated from \( \lambda_i \) as \( \hat{g}_i = \hat{g}_i(v_T^2, \lambda_i) \) with \( \hat{g}_i \) a real-valued function. Then, (32) converges to

\[
\Phi_t(v_T^2) \to \left( \frac{E[\hat{g}_i^2 \lambda_i^2]}{E[\hat{g}_i^2 \lambda_i]} \right) v_T^2 + \frac{E[\hat{g}_i^2]}{E[\hat{g}_i^2 \lambda_i]^2} \cdot \sigma^2, \tag{34}
\]

where the expectations (assumed to exist) are taken over the asymptotic eigenvalue distribution of \( A^T A \) (including the zero eigenvalues) and \( \hat{g}_i \) stands for \( \hat{g}_i(v_T^2, \lambda) \).

We further define

\[
\Psi_t (v_T^2) \equiv \left[ \eta_t (X + \tau_t Z) - X \right]^2, \tag{35}
\]

where \( \eta_t (r) \equiv C_t \cdot \left[ \hat{h}_t (r) - E[\hat{h}_t (X + \tau_t Z)] \cdot r \right] \) and \( X \) is independent of \( Z \sim N(0, 1) \). Then, (32), (23b) and (35), the SE for OAMP is given by (with \( v_0 = E[X^2] \))

\[
\begin{align*}
\text{LE:} & \quad \tau_t^2 = \Phi_t(v_T^2), \tag{36a} \\
\text{NLE:} & \quad v_{\tau_t+1}^2 = \Psi_t (v_T^2). \tag{36b}
\end{align*}
\]

The estimate for \( x \) in OAMP is generated by \( \eta_t^\text{out} \) rather than \( \eta_t \). Thus, the MSE performance of OAMP, measured by \( \|\hat{h}_t^\text{out}(r') - x\|^2/N \), is predicted as

\[
\Psi_t (v_T^2) \equiv \left[ \eta_t^\text{out} (X + \tau_t Z) - X \right]^2. \tag{37}
\]

B. OPTIMAL STRUCTURE OF OAMP

We now derive the optimal \( W_t \), \( \eta_t \) and \( \eta_t^\text{out} \) that minimize the MSE at the final iteration.

Let \( \Phi^*_t \), \( \Psi^*_t \), and \( \Psi^*_t \) be the minimums of \( \Phi_t \), \( \Psi_t \), and \( \Psi_t^\text{out} \) respectively (the minimizations are taken over \( W_t \), \( \eta_t \) and \( \eta_t^\text{out} \)). Lemmas 1 and 2 below will be useful to prove Theorem 2.

**Lemma 1:** The optimal \( W_t \) and \( \eta_t \) that minimize \( \Phi_t \) and \( \Psi_t \) in (32) and (35) are given by

\[
W_t^* = \frac{N}{\text{tr}(W_t A)} \tilde{W}_t, \tag{38a}
\]

\[
\eta_t^*(R') = C_t^* \cdot \left( \eta_t^\text{MMSE}(R') - \frac{mnse_B (\hat{\tau}_t^2)}{\hat{\tau}_t^2} \cdot R' \right). \tag{38b}
\]

where

\[
C_t^* \equiv \frac{\hat{\tau}_t^2}{\hat{\tau}_t^2 - mnse_B (\hat{\tau}_t^2)}, \tag{38c}
\]

\[
\eta_t^\text{MMSE}(R') \equiv E \left[ \|X\|^2 R' + X + \tau_t Z \right], \tag{38d}
\]

\[
mnse_B (\hat{\tau}_t^2) \equiv E \left[ \eta_t^\text{MMSE} - X \right]^2. \tag{38e}
\]

Furthermore, the optimal \( \eta_t^\text{out} \) that minimizes \( \Psi_t^\text{out} \) is given by \( \eta_t^\text{MMSE} \).

**Proof:** The optimality of \( \eta_t^\text{out} \) is by definition. The optimality of \( W_t^* \) and \( \eta_t^\text{out} \) are not so straightforward, due to the de-correlated constraint on \( W_t \) and the divergence-free constraint on \( \eta_t \). The details are given in Appendix B.
Substituting \(W^*_t; \eta^*_t\) and \((\eta^*_t)^*\) into (32), (35) and (37), and after some manipulations, we obtain

\[
\begin{align*}
\text{LE:} & \quad \Phi^*(v^2_t) = \left( \frac{1}{\text{mmse}_A(v^2_t)} - \frac{1}{v^2_t} \right)^{-1}, \quad (39a) \\
\text{NLE:} & \quad \psi^*(\tau^2_t) = \left( \frac{1}{\text{mmse}_B(\tau^2_t)} - \frac{1}{\tau^2_t} \right)^{-1}, \quad (39b) \\
\text{NLE:} & \quad (\psi^*_{\text{out}})^*(\tau^2_t) = \text{mmse}_B(\tau^2_t), \quad (39c)
\end{align*}
\]

where \(\text{mmse}_A(v^2_t) \equiv \frac{1}{N} \sum_{i=1}^{N} \frac{\sigma^2 \epsilon^2_{n}^2}{v^2_i + \sigma^2 + \epsilon^2_{n}^2}\) and \(\text{mmse}_B(\tau^2_t)\) is given in (38e). The derivations of (39a) are omitted, and the derivations for (39b) are shown in Appendix C-A. In (39), the subscript \(t\) has been omitted for the functions \(\Phi^*, \psi^*\) and \((\psi^*_{\text{out}})^*\) as they do not change across iterations.

**Lemma 2:** The functions \(\Phi^*, \psi^*,\) and \((\psi^*_{\text{out}})^*\) in (39) are monotonically increasing.

**Proof:** The monotonicity of \((\psi^*_{\text{out}})^*\) follows directly from the monotonicity of MMSE for additive Gaussian noise models [36]. The monotonicity of \(\Phi^*\) and \(\psi^*\) are proved in Appendix C-B.

According to the state evolution process, the final MSE can be expressed as

\[
\psi^*_{\text{out}}\left(\Phi_t\left(\psi^*_{t-1}\left(\cdots \left(\Phi_0\left(\frac{\eta^*_0}{\sqrt{M}}\right)\cdots\right)\right)\right)\right), \quad (40)
\]

From Lemmas 1 and 2, replacing any function (i.e., \(\Phi_t\), \(\psi_t\), and \((\psi^*_{\text{out}})^*\)) in (40) by its optimum reduces the final MSE. This leads to the following theorem.

**Theorem 2:** For the SE in (36), the final MSE in (40) is minimized by \(\{W_0^*, \ldots, W_{\infty}^*\}\), \(\{\eta_0^*, \ldots, \eta_{\infty}^*\}\) and \((\eta^*_t)^*\) given in Lemma 1.

Theorem 2 gives the optimal LE and NLE structures for the SE of OAMP. To compute \(\eta_t^*\) and \((\eta^*_t)^*\) in (38), we need to know the signal distribution \(P_x(x)\). In practical applications, such prior information may be unavailable. To approach the optimal performance for OAMP, the EM learning framework [34] or the parametric SURE approach [37] developed for AMP could be applicable to OAMP as well [38].

**C. POTENTIAL OPTIMALITY OF OAMP**

Note that the de-correlated constraint on \(W_t\) and the divergence-free constraint on \(\eta_t\) are restrictive. We now show that, provided that the SE in (36) is valid, OAMP is potentially optimal when the optimal \(\{W_t^*, \eta_t^*\}\) and \((\eta^*_t)^*\) given in Lemma 1 are used.

**Theorem 3:** When the optimal \(\{W_t^*\}\) and \(\{\eta_t^*\}\) in Lemma 1 are used, \(\{v_t^2\}\) and \(\{\tau_t^2\}\) are monotonically decreasing sequences. Furthermore, the stationary value of \(\tau_t^2\), denoted by \(\tau_{\infty}^2\), satisfies the following equation

\[
\frac{1}{\tau_{\infty}^2} = \frac{1}{\sigma^2} \cdot \text{RA}_{\tau_A}(\frac{1}{\sigma^2} \cdot \text{mmse}_B(\tau_{\infty}^2)), \quad (41)
\]

where \(\text{RA}_{\tau_A}\) denotes the R-transform [32, p. 48] w.r.t. the eigenvalue distribution of \(A^*A\).

**Proof:** See Appendix D.

Eqn. (41) is consistent with the fixed-point equation characterizing the MMSE performance for (1) (with \(A\) being unitarily-invariant) via the replica method [10, eq. (17)] [21]. This implies that OAMP can potentially achieve the optimal MSE performance. We can see that the \(\tau\)-correlated and divergence-free constraints on LE and NLE, though restrictive, do not affect the potential optimality of OAMP.

**V. NUMERICAL STUDY**

The following setups are assumed unless otherwise stated. The optimal \(\{W_t^*, \eta_t^*\}\) and \((\eta^*_t)^*\) given in Lemma 1 are adopted for OAMP. Furthermore, the approximation \(\text{mmse}_B(\tau_{\infty}^2) \approx \sum_{i=1}^{N} \text{var}(x)[v^2_t]/\eta^2\) is used for (38e). Following [17], we define SNR \(\equiv E\{\|Ax\|^2\}/E\{\|n\|^2\}\).

**A. IID GAUSSIAN MATRIX**

We start with an IID Gaussian matrix where \(A_{i,j} \sim \mathcal{N}(0, 1/M)\). Fig. 2 compares simulated MSE with SE prediction for OAMP and AMP. We first assume that the entries of \(X\) are independently BPSK modulated, so \(X\) is not sparse. This is a typical detection problem in massive MIMO applications. Fig. 2 compares simulated MSSEs with SE prediction for OAMP and AMP. In Fig. 2, OAMP-MF, OAMP-PINV and OAMP-LMMSE refer to, respectively, OAMP algorithms with the MF, PINV and LMMSE estimators given in (15) and the normalization in (14). The asymptotic SE formula in (34) becomes, respectively,

\[
\Phi^{\text{MF}}_t(\gamma^2_t) = \frac{N}{M} \cdot \gamma^2_t + \sigma^2, \quad (42a)
\]

\[
\Phi^{\text{PINV}}_t(\gamma^2_t) = \begin{cases} 
\frac{N - M}{M} \cdot \gamma^2_t + \frac{M}{N - M} \cdot \sigma^2 & \text{if } M < N \\
\frac{M}{N - M} \cdot \sigma^2 & \text{if } M > N 
\end{cases} \quad (42b)
\]

\[
\Phi^{\text{LMMSE}}_t(\gamma^2_t) = \frac{\sigma^2 + \gamma^2_t + \sqrt{\left(\sigma^2 + \gamma^2_t\right)^2 + 4\sigma^2 \gamma^2}}{2}, \quad (42c)
\]

where \(c \equiv (N - M)/M\). Comparing (42a) and (42b), we see that OAMP-PINV has better interference cancellation property than OAMP-MF (but less robust to noise). This is consistent with the observation in Fig. 2 (which represents a high SNR scenario) that OAMP-PINV can outperform OAMP-MF.

From Fig. 2, we observe good agreement between the simulated and predicted MSE for all curves. Furthermore, we see that AMP has the same convergent value as OAMP-LMMSE for IID Gaussian matrices, while the latter converges faster. Following the approach in [39], we can prove this observation but the details are omitted due to space limitation.

**B. GENERAL UNITARILY-INVARIANT MATRIX**

We next turn our attention to more general sensing matrices. Following [17], let \(A = V \Sigma U^T\), where \(V \) and \(U\) are independent Haar-distributed matrices (or isotropically random
orthogonal matrices [32]. The nonzero singular values are set to be \( \lambda_i/\lambda_{i+1} = \kappa^{1/M} \) for \( i = 1, \ldots, M - 1 \), and \( \sum_{i=1}^{M} \lambda_i = N \). Here, \( \kappa \geq 1 \) is the condition number of \( A \). We consider sparse signals, generated according to a Bernoulli-Gaussian distribution:

\[
P_X(x) = \rho \cdot N(x; 0, \rho^{-1}) + (1 - \rho) \cdot \delta(x),
\]

where \( \rho \in (0, 1] \) is a sparsity level and \( \delta(\cdot) \) is the Dirac delta function.

Fig. 3 shows the simulated and predicted MSEs for OAMP for the above ill-conditioned sensing matrix. The SE of OAMP is based on the empirical form in (32) as \( \{\lambda_i\} \) are fixed in this example. We can make the following observations.

- The performances of AMP and OAMP-MF deteriorate in this case. The SE prediction for AMP is not shown in Fig. 3 since it is noticeably different from the simulation result. (See Fig. 1 for a similar issue.)
- The performance of OAMP is strongly affected by the LE structure. OAMP-PINV and OAMP-LMMSE significantly outperform OAMP-MF.
- The most interesting point is that the SE in (36) can accurately predict the OAMP simulation results for all the LE structures in Fig. 3. We observed in simulations that such good agreement also holds for LEs beyond the three options shown in Fig. 3.

Fig. 4 compares the MSE performances of AMP, OAMP and genie-aided MMSE (where the positions of the non-zero entries are known) as the condition number of \( A \) varies. AMP with adaptive damping (AMP-damping) [17] (based on the Matlab code released by its authors\(^8\) and the parameters used in [17, Fig. 1]) and GAMP-ADMM [19] are also shown. From Fig. 4, we can see that the performance of OAMP-LMMSE is significantly better than those of AMP, AMP-damping and ADMM-GAMP for highly ill-conditioned scenarios. (ADMM-GAMP slightly outperforms OAMP-LMMSE for \( \kappa \leq 100 \) since the former involves more iterations in this example.) OAMP-PINV has worse performance than AMP when \( \kappa \geq 10 \) but performs reasonably well for large \( \kappa \). OAMP-MF does not work well and thus not included.

For the schemes shown in Fig. 4, AMP have the lowest complexity. OAMP-PINV requires one additional matrix inversion, but it can be pre-computed as it remains unchanged during the iterations. Both OAMP-LMMSE and ADMM-GAMP require matrix inversions in each iteration. As pointed out in [19], it may be possible to replace the matrix inversion

\(^8\)Available at http://sourceforge.net/projects/gampmatlab/
in ADMM-GAMP using an iterative method such as conjugate gradient [40]. Similar approximation should be possible for OAMP as well.

C. PARTIAL ORTHOGONAL MATRIX

In the examples used above, matrix inversion is involved for \( \hat{W}_{\text{PINV}} \) and \( \hat{W}_{\text{LMMSE}} \) in (15b) and (15c), so their complexity per iteration can be higher than that of AMP. (Note that the overall complexity also depends on the convergence speed, for which AMP and OAMP behave differently as seen in Fig. 4.) In the following, we will consider partial orthogonal matrices characterized by \( AA^T = N/M \cdot I \) (here \( N/M \) is a normalization constant). Then inversion operation is not necessary. For example, in this case \( \hat{W}_{\text{LMMSE}} \) is given by

\[
\hat{W}_{\text{LMMSE}} = v_t^2 A^T \left( v_t^2 AA^T + \sigma^2 I \right)^{-1}
\]

\[
= \frac{v_t^2}{N/M \cdot v_t^2 + \sigma^2} A^T.
\]

Therefore, the complexity of OAMP-LMMSE is the same as AMP.

Unitarily invariant matrices with the partial orthogonality constraint becomes partial Haar-distributed matrices (i.e., uniformly distributed among all partial orthogonal matrices). We next consider the following partial orthogonal matrix

\[ A = \sqrt{\frac{N}{M}} SU^T, \]

where \( S \) consists of \( M \) uniformly randomly selected rows of the identity matrix and \( U \) is an Haar-distributed orthogonal matrix. We will also consider deterministic orthogonal matrices, which are important in compressed sensing and found applications in, e.g., MRI [41]. For a partial orthogonal \( A \), the three approaches in Fig. 2, i.e., OAMP-MF, OAMP-PINV and OAMP-LMMSE, become identical. The related complexity is the same as AMP. In this case, the SE equation in (32) becomes

\[
\Phi_t \left( v_t^2 \right) = \frac{N}{M} \cdot v_t^2 + \sigma^2.
\]

Fig. 5 compares OAMP with AMP in recovering Bernoulli-Gaussian signals with a partial DCT matrix. Following [34], we will use the empirical phase transition curve (PTC) to characterize the sparsity-undersampling tradeoff. A recovery algorithm “succeeds” with high probability below the PTC and “fails” above it. The empirical PTCs are generated according to [34, Sec. IV-A]. We see that OAMP considerably outperforms AMP when both algorithms are fixed to 50 iterations. Even when the number of iterations of AMP is increased to 500, OAMP still slightly outperforms AMP at relatively high sparsity levels.

Fig. 6 shows the accuracy of SE for OAMP with partial orthogonal matrices. Three types of partial orthogonal matrices when \( N \) is sufficiently large (\( N = 8192 \) in this case). It should be noted that, when \( M/N \) is larger, a smaller \( N \) will suffice to guarantee good agreement between simulation and SE prediction.

The NLEs used in Figs. 2-6 are based on the optimized structure given in Lemma 1. Fig. 7 shows the OAMP SE accuracy with the following soft-thresholding function [31]:

\[
\hat{\eta}_t \left( r \right) = \max \left( |r| - \gamma_t, 0 \right) \cdot \text{sign} \left( r \right),
\]

where \( \gamma_t \geq 0 \) is a threshold and \( \text{sign}(r) \) is the sign of \( r \). According to (25), the divergence-free function \( \eta_t \) is
constructed as
\[
\eta_t(r') = C_t \left( \hat{\eta}_t(r') - \left( \frac{1}{N} \sum_{j=1}^{N} \mathbb{1}(\left| r'_j \right| > \gamma_t) \right) \cdot r' \right),
\]
(48)
where \( \mathbb{1}(\cdot) \) is the indicator function. Further, we set \( \eta_t^{\text{out}} = \hat{\eta}_t \) for simplicity. The function in (47) is not optimal under the MMSE sense in Lemma 1. However, it is near minimax for sparse signals [42] and widely studied in compressed sensing. The optimal \( C_t \) is different from that given in Lemma 1 in this case. We will not discuss details in optimizing \( C_t \) here. Rather, to demonstrate the accuracy of SE, three arbitrarily chosen values for \( C_t \) are used in Fig. 7. We see that simulation and SE predictions agree well for all cases. In particular, when \( C_t = 3 \), SE is able to predict the OAMP behavior even when iterative processing leads to worse MSE performance.

VI. CONCLUSIONS
AMP performs excellently for IID Gaussian transform matrices. The performance of AMP can be characterized by SE in this case. However, for other matrix ensembles, the SE for AMP is not directly applicable and its performance is not warranted.

In this paper, we proposed an OAMP algorithm based on a de-correlated LE and a divergence-free NLE. Our numerical results indicate that OAMP could be characterized by SE for general unitarily-invariant matrices with much relaxed requirements on the eigenvalue distribution and LE structure. This makes OAMP suitable for a wider range of applications than AMP, especially for applications with ill-conditioned transform matrices and partial orthogonal matrices. We also derived the optimal structures for OAMP and showed that the corresponding SE fixed point potentially coincides with that of the Bayes-optimal performance obtained by the replica method.

APPENDIX A
PROOF OF PROPOSITION 1
It is seen from (21b) that \( q' \) generated by the NLE is generally correlated with \( x \), which may lead to the correlation between \( x \) and \( h' \). We will see below that a de-correlated LE can suppress this correlation.

From \( A = V \Sigma U^T \), \( W_t = U G_t V^T \) and \( B = I - W_t A = U(I - G_t \Sigma) U^T \), so
\[
E \left\{ (B_t)_{i,j} \right\} = \sum_{m=1}^{N} E \left\{ U_{i,m} U_{j,m} \right\} \cdot (1 - g_m \lambda_m),
\]
(49)
where \( g_m \) and \( \lambda_m \) denote the \((m,m)\)th diagonal entries of \( G_t \) and \( \Sigma \), respectively. (We define \( g_m = \lambda_m = 0 \) for \( m = M + 1, \ldots, N \).) For a Haar distributed matrix \( U \), we have [43, Lemma 1.1 and Proposition 1.2]
\[
E\{U_{i,m} U_{j,m}\} = \begin{cases} 0 & \text{if } i \neq j, \\ N^{-1} & \text{if } i = j. \end{cases}
\]
(50)
Therefore,
\[
E \left\{ (B_t)_{i,j} \right\} = \begin{cases} 0 & \text{if } i \neq j, \\ N^{-1} \text{tr}(B_t) & \text{if } i = j. \end{cases}
\]
(51)
From the discussions in Section III-A, when \( W_t \) is de-correlated, \( \text{tr}(B_t) = \text{tr}(I - W_t A) = 0 \). Together with (51), this further implies \( E\{B_t\} = 0 \).

From Assumption 1, \( q' \) is independent of \( A \) (and so \( B_t \)). Then,
\[
E\{h'\} = E\{B_t q'\} + E\{W_t n\}
= E\{B_t\} E\{q'\} + E\{W_t\} E\{n\}
= 0.
\]
(52a)
(52b)
(52c)
From (21a), to prove \( x \) is uncorrelated with \( h' \), we only need to prove \( x \) is uncorrelated with \( B_t q' \) since \( W_t n \) is independent of \( x \). This can be verified as
\[
E \left\{ B_t q' x^T \right\} = E\{B_t\} E\{q' x^T\} = 0.
\]
(53)
Following similar procedures, we can also verify that (i) the entries in \( h' \) are uncorrelated, and (ii) the entries of \( h' \) have identical variances. We omit the details here.

APPENDIX B
PROOF OF LEMMA 1
A. OPTIMALITY OF \( W_t^* \)
We can rewrite \( \Phi_t(v_t^2) \) in (32) as
\[
\Phi_t(v_t^2) = \left( \frac{1}{N} \sum_{i=1}^{N} \hat{g}_i \lambda_i^2 (1 + \frac{\gamma_t}{\sqrt{\lambda_i^2 + \sigma^2}}) \right) - v_t^2.
\]
(54)
We now prove that \( W_t^* \) in Lemma 1 is optimal for (54). To this end, define \( \alpha_t \equiv \hat{g}_t \sqrt{\lambda_t^2 + \sigma^2} \), and \( \beta_t \equiv \lambda_t / \sqrt{\lambda_t^2 + \sigma^2} \). Applying the Cauchy-Schwarz inequality
\[
\frac{1}{N} \sum_{i=1}^{N} a_i^2 \geq \left( \frac{1}{N} \sum_{i=1}^{N} b_i^2 \right)^{-1},
\]
(55)
leads to
\[
\frac{1}{N} \sum_{i=1}^{N} \frac{\hat{g}_i^2 (v_i^2 \lambda_i^2 + \sigma^2)}{(\frac{1}{N} \sum_{i=1}^{N} \hat{g}_i \lambda_i)^2} \geq \left( \frac{1}{N} \sum_{i=1}^{N} \frac{\lambda_i^2}{v_i^2 \lambda_i^2 + \sigma^2} \right)^{-1},
\]
(56)
where the right hand side of (56) is invariant to \{\hat{g}_i\}. The minimum in (56) is reached when
\[
\hat{g}_i^* \sqrt{v_i^2 \lambda_i^2 + \sigma^2} = C \sqrt{\frac{\lambda_i^2}{v_i^2 \lambda_i^2 + \sigma^2}},
\]
(57)
where \(C\) is an arbitrary constant. From (57),
\[
\hat{g}_i^* = C \frac{\lambda_i}{\sqrt{v_i^2 \lambda_i^2 + \sigma^2}}.
\]
(58)
Recall that \{\lambda_i\} are the singular values of \(A\). Setting \(C = v_i^2\), we can see that \{\hat{g}_i^*\} obtained from (58) are the singular values of \(\hat{W}_t^{LMMSE} \equiv v_i^2 A^T (v_i^2 AA^T + \sigma^2)^{-1}\) in (15c). Therefore the optimal \(W_t^*\) can be obtained by substituting \(\hat{W}_t^{LMMSE}\) into (14):
\[
W_t^* = \frac{N}{\text{tr}(\hat{W}_t^{LMMSE} A)} \hat{W}_t^{LMMSE}.
\]
(59)

**B. OPTIMALITY OF \(\eta_t^*\)**
The SE equation in (35) are obtained based on the following signal model
\[
R' = X + \tau_t Z.
\]
(60)
The following identity is from [44, eq. (123)]
\[
\frac{d \eta_t^{MMSE} }{d R' } = \frac{1}{\tau_t} \cdot \text{var} \{X | R' \},
\]
(61)
where \(\eta_t^{MMSE} \equiv E \{X | R' \}\) (see (38d)). Using (61) and noting \(\text{mse}_B(\tau_t^2) = E[\text{var}(X | R')]\), we can verify that \(\eta_t^*\) in (38b) is a divergence-free function (see (18)).

Lemma 3 below is the key to prove the optimality of \(\eta_t^*\).

**Lemma 3:** The following holds for any divergence-free function \(\eta_t\)
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - \eta_t^*) \} = 0.
\]
(62)
**Proof:** We can rewrite (38b) as
\[
\eta_t^* = C_t^* \cdot \eta_t^{MMSE} + (1 - C_t^*) \cdot R'.
\]
(63)
First,
\[
\eta_t^{MMSE} - \eta_t^* = \eta_t^{MMSE} - \left[ C_t^* \cdot \eta_t^{MMSE} + (1 - C_t^*) \cdot R' \right]
\]
(64a)
\[
= (1 - C_t^*) \cdot \left( \eta_t^{MMSE} - R' \right).
\]
(64b)
Therefore, to prove Lemma 3, we only need to prove
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - R') \} = 0.
\]
(65)
Substituting \(R' = X + \tau_t Z\) into (65) yields
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - X - \tau_t Z) \} = 0.
\]
(66)
Since \(\eta_t^*\) is a divergence-free function of \(R'\), we have the following from (26)
\[
E \{ \eta_t \cdot Z \} = 0.
\]
(67)
Substituting (67) into (66), proving Lemma 3 becomes proving
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - X) \} = 0.
\]
(68)
Note that \(\eta_t\) and \(\eta_t^{MMSE}\) are deterministic functions of \(R'\). Then, conditional on \(R'\), we have
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - X) | R' \}\]
\[
= \eta_t \cdot \left( \eta_t^{MMSE} - E \{X | R' \} \right)
\]
(69a)
\[
= \eta_t \cdot (\eta_t^{MMSE} - \eta_t^{MMSE})
\]
(69b)
\[
= 0,
\]
(69c)
where (69b) is from the definition of \(\eta_t^{MMSE}\) in (38d). Therefore,
\[
E \{ \eta_t \cdot (\eta_t^{MMSE} - X) \} = E \{ \eta_t \cdot (\eta_t^{MMSE} - X) | R' \}
\]
\[
= 0,
\]
(70)
which concludes the proof of Lemma 3.

We next prove the optimality of \(\eta_t^*\) based on Lemma 3. Again, let \(\eta_t\) be an arbitrary divergence-free function of \(R'\). The estimation MSE of \(\eta_t\) reads
\[
\Psi_t(\tau_t^2) \equiv E \{ (\eta_t - X)^2 \}
\]
(71a)
\[
= E \{ (\eta_t - \eta_t^{MMSE} + \eta_t^{MMSE} - X)^2 \}
\]
(71b)
\[
= E \{ (\eta_t - \eta_t^{MMSE})^2 \} + E \{ (\eta_t^{MMSE} - X)^2 \}
\]
(71c)
\[
= E \{ (\eta_t - \eta_t^{MMSE})^2 \} + \text{mse}_B(\tau_t^2),
\]
(71d)
where the cross terms in (71c) disappears due to the orthogonality property of MMSE estimation [1] (recall that \(\eta_t^{MMSE}\) is the scaler MMSE estimator). We see from (71) that finding \(\eta_t\) that minimizes \(E \{ (\eta_t - X)^2 \}\) is equivalent to finding \(\eta_t\) minimizing \(E \{ (\eta_t - \eta_t^{MMSE})^2 \}\). We can further rewrite
\[
E \{ (\eta_t - \eta_t^{MMSE})^2 \}
\]
as
\[
E \{ (\eta_t - \eta_t^{MMSE})^2 \}
\]
(72a)
\[
= E \{ (\eta_t - \eta_t^* + \eta_t^* - \eta_t^{MMSE})^2 \}
\]
(72b)
\[
= E \{ (\eta_t - \eta_t^*)^2 \} + E \{ (\eta_t^* - \eta_t^{MMSE})^2 \}
\]
(72c)
From Lemma 3, we have $E\left\{ \eta_t \cdot (\eta_t^* - \eta_t^{\text{MMSE}}) \right\} = 0$ and $E\left\{ \eta_t^* \cdot (\eta_t^* - \eta_t^{\text{MMSE}}) \right\} = 0$ (since $\eta_t^*$ is itself a divergence-free function). Then, (72) becomes

$$E \left\{ \left( \eta_t - \eta_t^{\text{MMSE}} \right)^2 \right\} = E \left\{ \left( \eta_t - \eta_t^* \right)^2 \right\} + E \left\{ \left( \eta_t^* - \eta_t^{\text{MMSE}} \right)^2 \right\},$$

(73a)

$$\geq E \left\{ \left( \eta_t^* - \eta_t^{\text{MMSE}} \right)^2 \right\},$$

(73b)

where the equality is obtained when $\eta_t = \eta_t^*$, and the right hand side of (73c) is a constant invariant of $\eta_t$. Hence, $\eta_t = \eta_t^*$ minimizes $E \left\{ \left( \eta_t - \eta_t^{\text{MMSE}} \right)^2 \right\}$ and so $\Psi_t \equiv E \left\{ (\eta_t - X)^2 \right\}$. This completes the proof.

**APPENDIX C**

**PROOF OF LEMMA 2**

**C. DERIVATION OF $\Psi^*$ IN (39b)**

Using (63), we have

$$\Psi^* \left( \tau_i^2 \right) = E \left\{ \left( \eta_i^* - X \right)^2 \right\}$$

(74a)

$$= E \left\{ \left( C_i^* \cdot \eta_i^{\text{MMSE}} + \left( 1 - C_i^* \right) \cdot R' - X \right)^2 \right\}$$

(74b)

$$= (C_i^*)^2 E \left\{ \left( \eta_i^{\text{MMSE}} - X \right)^2 \right\} + (1 - C_i^*)^2 E \left\{ \left( R' - X \right)^2 \right\}$$

(74c)

$$+ 2C_i^* (1 - C_i^*) E \left\{ (\eta_i^{\text{MMSE}} - X) \tau_i Z \right\}$$

(74d)

$$= (C_i^*)^2 \cdot \text{mmse}_B \left( \tau_i^2 \right) + (1 - C_i^*)^2 \cdot \tau_i^2$$

$$+ 2C_i^* (1 - C_i^*) \cdot \text{mmse}_B \left( \tau_i^2 \right)$$

(74e)

$$= \left( \frac{1}{\text{mmse}_B \left( \tau_i^2 \right)} - \frac{1}{\tau_i^2} \right)^{-1},$$

(74f)

where (74e) is from the fact that $E[XZ] = 0$, Stein’s lemma and (61), (74f) from the definition of $C_i^*$ in (38).

**D. MONOTONICITY OF $\Phi^*$ AND $\Psi^*$**

We first verify the monotonicity of $\Phi^*$. From (39a) and after some manipulations, we obtain

$$d\Phi^* \left( \frac{v_i^2}{\tau_i^2} \right) = \frac{v_i^2 \cdot \text{mmse}_A \left( v_i^2 \right) - \text{mmse}_A \left( v_i^2 \right)}{v_i^2 \cdot \text{mmse}_A \left( v_i^2 \right)}. \quad (75)$$

To show the monotonicity of $\Phi^*$, we only need to show that

$$\frac{d\text{mmse}_A \left( v_i^2 \right)}{dv_i^2} \geq \left( \frac{\text{mmse}_A \left( v_i^2 \right)}{v_i^2} \right)^2. \quad (76)$$

The derivative of $\text{mmse}_A \left( v_i^2 \right)$ can be computed based on the definition below (39). After some manipulations, the inequality in (76) becomes the inequality below

$$\frac{1}{N} \sum_{i=1}^{N} \left( \frac{\sigma^2}{v_i^2 \lambda_i^2 + \sigma^2} \right)^2 \geq \left( \frac{1}{N} \sum_{i=1}^{N} \frac{\sigma^2}{v_i^2 \lambda_i^2 + \sigma^2} \right)^2. \quad (77)$$

which holds due to Jensen’s inequality.

The monotonicity of $\Psi^*$ can be proved in a similar way. Again, we only need to prove that

$$\frac{d\text{mmse}_B \left( v_i^2 \right)}{dv_i^2} \geq \left( \frac{\text{mmse}_B \left( v_i^2 \right)}{v_i^2} \right)^2. \quad (78)$$

Note that $\text{mmse}_B \left( v_i^2 \right) = E \left\{ \left[ X - E \left\{ X | R' = X + \tau_i Z \right\} \right]^2 \right\}$

From [36, Proposition 9], we have

$$\frac{d\text{mmse}_B \left( v_i^2 \right)}{dv_i^2} = E \left\{ \left[ \text{var} \left\{ X | R' \right\} \right]^2 \right\} \quad (79)$$

Applying Jensen’s inequality, we have

$$E \left\{ \text{var} \left\{ X | R' \right\} \right\} \geq \left[ E \left\{ \text{var} \left\{ X | R' \right\} \right\} \right]^2 = \left[ \text{mmse}_B \left( v_i^2 \right) \right]^2. \quad (80)$$

which, together with (79), proves (78).

**APPENDIX D**

**PROOF OF THEOREM 3**

**E. MONOTONICITY OF $\left\{ v_i^2 \right\}$ AND $\left\{ \tau_i^2 \right\}$**

We first show that $\left\{ v_i^2 \right\}$ decrease monotonically. From (39b),

$$\lim_{\tau^2 \to \infty} \Phi^* \left( \tau^2 \right) = \lim_{\tau^2 \to \infty} \frac{\tau^2 \cdot \text{mmse}_B \left( \tau^2 \right)}{\tau^2 \cdot \text{mmse}_B \left( \tau^2 \right) - \tau^2} = \lim_{\tau^2 \to \infty} \text{mmse}_B \left( \tau^2 \right) = E[X^2] \quad (81a)$$

$$\left. \right| = v_0^2, \quad (81d)$$

where (81d) is from the initialization of the SE. Since $\Phi^* \left( v_0^2 \right) < \infty$ and $\Psi^*$ is a monotonically increasing function, we have $v_1^2 = \Phi^* \left( \Phi^* \left( v_0^2 \right) \right) < v_0^2$.

We now proceed by induction. Suppose that $v_i^2 < v_{i-1}^2$. Since both $\Phi^*$ and $\Psi^*$ are monotonically increasing, we have $\Psi^* \left( \Phi^* \left( v_i^2 \right) \right) < \Psi^* \left( \Phi^* \left( v_{i-1}^2 \right) \right)$, which, together with the SE relationship $v_{i+1}^2 = \Phi^* \left( \Phi^* \left( v_i^2 \right) \right)$, leads to $v_{i+1}^2 < v_i^2$. Hence, $\left\{ v_i^2 \right\}$ is a monotonically decreasing sequence.

The monotonicity of the sequence $\left\{ \tau_i^2 \right\}$ follows directly from the monotonicity of $\left\{ v_i^2 \right\}$, the SE $\tau_i^2 = \Phi^* \left( v_i^2 \right)$, and the fact that $\Phi^*$ is a monotonically increasing function.

**F. FIXED POINT EQUATION OF SE**

Similar to (34),

$$\text{mmse}_A \left( v_i^2 \right) = \frac{1}{N} \sum_{i=1}^{N} \frac{v_i^2 \cdot \sigma^2}{v_i^2 \cdot \lambda_i^2 + \sigma^2} \rightarrow E \left\{ \frac{v_i^2 \cdot \sigma^2}{v_i^2 \cdot \lambda_i^2 + \sigma^2} \right\}. \quad (82)$$
where the expectation is w.r.t. the asymptotic eigenvalue distribution of \( A^T A \). From the definition of the \( \eta \)-transform in [32, p. 40], we can write

\[
\gamma^2 \cdot \eta_{A^T A} \left( \frac{\gamma^2}{\sigma^2} \right) = E \left\{ \frac{v_i^2 \cdot \sigma^2}{\gamma^2 \cdot \lambda_i^2 + \sigma^2} \right\},
\]

(83)

where \( \eta_{A^T A} \) denotes the \( \eta \)-transform. For convenience, we further rewrite (83) as

\[
\gamma \cdot \eta_{A^T A} \left( \frac{\gamma^2}{\sigma^2} \right) = \frac{1}{\sigma^2} \cdot mmse_{A} \left( \frac{\gamma^2}{\sigma^2} \right).
\]

(84)

where \( \gamma \equiv \gamma^2 / \sigma^2 \). Note the following relationship between the \( \eta \)-transform and the \( R \)-transform [32, eq. (2.74)]

\[
R_{A^T A} \left( -\gamma \cdot \eta_{A^T A} \left( \gamma \right) \right) = \frac{1}{\gamma} - \eta_{A^T A} \left( \gamma \right).
\]

(85)

Substituting (84) into (85) yields

\[
R_{A^T A} \left( -\frac{1}{\sigma^2} \cdot mmse_{A} \left( \gamma^2 \right) \right) = \frac{\sigma^2}{mmse_{A} \left( \gamma^2 \right)} - \frac{\sigma^2}{\gamma^2} = \frac{\sigma^2}{\gamma^2} \cdot \frac{1}{\gamma^2},
\]

(86)

where the second equality in (86) is from (36a) and (39a). We can rewrite the SE equations in (39a) and (39b) as follows

\[
mmse_{A} \left( \gamma^2 \right) = \left( \frac{1}{\tau^2} + \frac{1}{\gamma^2} \right)^{-1},
\]

(87a)

\[
mmse_{B} \left( \tau^2 \right) = \left( \frac{1}{\tau^2} + \frac{1}{\gamma^2} \right)^{-1}.
\]

(87b)

At the stationary point, we have

\[
mmse_{A} \left( \gamma^2 \right) \Rightarrow mmse_{B} \left( \tau^2 \right).
\]

(88)

Substituting (88) into (86), we get the desired fixed point equation

\[
\frac{1}{\tau^2} = \frac{1}{\sigma^2} \cdot R_{A^T A} \left( -\frac{1}{\sigma^2} \cdot mmse_{B} \left( \gamma^2 \right) \right).
\]

(89)
