q—WIENER AND (α, q)—ORNSTEIN–UHLENBECK PROCESSES.
A GENERALIZATION OF KNOWN PROCESSES

PAWEŁ J. SZABŁOWSKI

ABSTRACT. We collect, scattered through literature, as well as we prove some
new properties of two Markov processes that in many ways resemble Wiener
and Ornstein–Uhlenbeck processes. Although processes considered in this pa-
er were defined either in non-commutative probability context or through
quadratic harnesses we define them once more as to say ‘continuous time’
generalization of a simple, symmetric, discrete time process satisfying simple
conditions imposed on the form of its first two conditional moments. The finite
dimensional distributions of the first one (say \( X = (X_t)_{t \geq 0} \) called q—Wiener)
depends on one parameter \( q \in (-1, 1] \) and of the second one (say \( Y = (Y_t)_{t \in \mathbb{R}} \)
called (\( \alpha, q \))—Ornstein–Uhlenbeck) on two parameters \( (\alpha, q) \in (0, \infty) \times (-1, 1] \).
The first one resembles Wiener process in the sense that for \( q = 1 \) it is Wiener
process but also that for \( |q| < 1 \) and \( \forall n \geq 1 : t^{n/2} H_n(X_t/\sqrt{t}q) \), where
\( (H_n)_{n \geq 0} \) are the so called q—Hermite polynomials, are martingales. It does
not have however neither independent increments not allows continuous sam-
ple path modification. The second one resembles Ornstein–Uhlenbeck process.
For \( q = 1 \) it is a classical OU process. For \( |q| < 1 \) it is also stationary with
correlation function equal to \( \exp(-\alpha |t - s|) \) and has many properties resem-
bling those of its classical version. We think that these process are fascinating
objects to study posing many interesting, open questions.

1. INTRODUCTION

As announced in the abstract, we are going to define two time-continuous fami-
lies of Markov processes. One of them will resemble Wiener process and the other
Ornstein–Uhlenbeck (OU) process. They will be indexed (apart from time param-
eter) by additional parameter \( q \in (-1, 1] \). In the case \( q = 1 \) these processes are
classical Wiener and OU process. Of course for OU process there will be addi-
tional parameter \( \alpha > 0 \) responsible for covariance function of the process. For
\( q \in (-1, 1) \) both processes will assume values in a compact space : \( (\alpha, q)\)—OU
process on \( [-\sqrt{1-q}, \sqrt{1-q}] \), while for q—Wiener process \( (X_t)_{t \geq 0} \) we will have:
\( X_t \in [-2\sqrt{1-q}, 2\sqrt{1-q}] \). One dimensional probabilities and transitional prob-
obabilities of these processes will be given explicitly. Moreover two families of poly-
nomials, orthogonal with respect to these measures, will also be presented. Some
properties of conditional expectations given the past and also past and the future

Date: February, 2009.

2000 Mathematics Subject Classification. Primary 60J25, 60G44; Secondary 05A30, 60K40.

Key words and phrases. q—Wiener process, q—Ornstein–Uhlenbeck process, polynomial mar-
tingales property, q-Gaussian distributions, quadratic harnesses, strong Markov property, Feller
continuity, q—Hermite polynomials, Al-Salam–Chihara polynomials.

The author is grateful to an unknown referee for pointing out subtle questions concerning some
proofs, hasty thoughtlessness in posing open questions and numerous misprints.

1
will be exposed. Martingale properties, as well as some properties of sample path of these processes will be described. Thus quite detailed knowledge concerning these processes will be presented.

The processes that we are going to reintroduce have appeared already in 1997 in an excellent paper \cite{20} as an offspring and a particular case of some non-commutative probability model. Some of the properties of these processes particularly those associated with martingale behavior of some functions of these processes were also discussed in this paper. Since 1997 there appeared couple of papers on the properties of $q$-Gaussian distributions. See e.g. \cite{11}, \cite{23}, \cite{21}.

There is also a different path of research followed by Włodek Bryc, Wojtek Matysiak and Jacek Wesolowski see e.g. \cite{9}, \cite{10}, \cite{13}. Their starting point is a process with continuous time that satisfies several (exactly 5) conditions on covariance function and on the first and the second conditional moments. Those are the so called quadratic harnesses characterized by 5 parameters. Under resulting 5 assumptions they proved that these processes are Markov and also stated several properties of the families of polynomials that orthogonalize transitional and one dimensional probabilities. They gave several examples illustrating developed theory. One of the processes considered by them is the so called $q$-Brownian process. 4 of 5 possible parameters are equal to zero and the fifth one can be identified with parameter $q$ considered in this paper. As far as the one dimensional probabilities and the transitional probabilities are concerned this process is identical with $q$-Wiener process introduced and analyzed in this paper. They did not however work on the properties of the $q$-Brownian process. It appeared as a by-product of their interest in quadratic harnesses. Bryc Matysiak and Wesolowski were mostly interested in the general problem of existence of quadratic harnesses. That is why $(\alpha, q)$-OU process have not appeared in their works.

What we are aiming to do is to reintroduce these processes via certain discrete time one dimensional, time symmetric random process (1TSP) by the so to say ”continuation of time” or may be more precisely as processes that sampled at certain discrete moments have the properties of 1TSP. This discrete time process was defined in a purely classical probability context. Moreover it is very simple and intuitive. Its simplicity surprised Richard Askey ”that it has no $q$ in the statement of the problem” as he puts it in the forward to \cite{5}. Thus these 1TSP can be simple models of some phenomena observed in the recently intensively developing $q$-series theory. 1TSP first appeared in 2000 in \cite{1} and have been studied in detail recently see e.g. \cite{2}, \cite{3}, \cite{7}, \cite{8}.

Besides we derive these processes under fewer assumptions (than one would need while following quadratic harnesses path) on the first and the second conditional moments (we need only 2). The construction is also different. As mentioned earlier our starting point is a discrete time 1TSP. $q$-Wiener process is obtained as continuous time transformation of the process that we call $(\alpha, q)$-OU process (like in the classical i.e. $q = 1$ case) which, on its side, is obtained as continuous time generalization of the discrete time process (1TSP). Besides we list many properties of $q$-Wiener process that justify its name (are sort of $q$- analogies of well known martingale properties of Wiener process). Some of these properties can be derived from the definition of $q$-Brownian process presented in \cite{9}. They are not however stated explicitly.
That is why the first section will be dedicated to definition of 1TSP’s and recollection of their basic properties. Since our approach is totally commutative $q$–by no means is an operator. It is a number parameter. Yet we are touching the $q$–series theory and the special functions.

We think that processes presented in this paper are the fascinating objects to study. As mentioned before, for $|q| < 1$ $q$–Wiener process has many properties similar to ordinary Brownian motion, but is not an independent increment process. Besides we present a few properties of trajectories of the processes discussed in this paper. Properties that, although can be relatively easily deduced, were never stated in the above mentioned papers where these processes appeared first.

The paper is organized as follows. As we mentioned, in the second section we recall definition and summarize basic properties of 1TSP’s. The next section is still dedicated mainly to certain auxiliary properties of the discrete time 1TSP’s that are necessary to perform our construction. In the fourth section we introduce continuous version of 1TSP $(\alpha, q)$–OU process and prove its existence. Then we define $q$–Wiener as a continuous time transformation of $(\alpha, q)$–OU process. Later parts of this section are devoted to presentation of the two processes and listing or proving some of their properties. We indicate their connection with an emerging quadratic harness theory.

We point out here where is the mistake causing that Weso/suppress lowski’s martingale characterization of the Wiener process contained in [19] is not true. The fact that is not true was already known to Weso/suppress lowski (see e.g. [9] where processes denying his characterization are pointed out).

The fifth section presents some obvious open problems that come to mind almost directly. The last (sixth) section contains lengthy proofs of the results from the previous sections.

It is known that 1TSP exist with parameter $q > 1$ (see [14]). It’s transition distribution is then discrete. We show in this paper that $q$–Wiener and $(\alpha, q)$–Ornstein–Uhlenbeck processes do not exist for $q > 1$.

2. ONE DIMENSIONAL TIME SYMMETRIC RANDOM PROCESSES

By 1TSP’s we mean square integrable random field $X = \{X_n\}_{n \in \mathbb{Z}}$ indexed by the integers, with non-singular all covariance matrices and constant first two moments, that satisfy the following two sets of conditions :

\[
(2.1) \quad \exists a, b \in \mathbb{R}; \forall n \in \mathbb{Z} : \mathbb{E} (X_n | \mathcal{F}_{\neq n}) = a (X_{n-1} + X_{n+1}) + b, \text{ a.s.}
\]

and

\[
(2.2a) \quad \exists A, B, C \in \mathbb{R}; \forall n \in \mathbb{Z} : \mathbb{E} (X_n^2 | \mathcal{F}_{\neq n}) = \\
(2.2b) \quad A (X_{n-1}^2 + X_{n+1}^2) + BX_{n-1}X_{n+1} + D (X_{n-1} + X_{n+1}) + C, \text{ a.s.,}
\]

where $\mathcal{F}_{\neq m} := \sigma (X_k : k \neq m)$.

Let us define also $\sigma$–algebras $\mathcal{F}_{\leq m} := \sigma (X_k : k \leq m)$, $\mathcal{F}_{\geq m} := \sigma (X_k : k \geq m)$, and $\mathcal{F}_{\leq m, \geq j} := \sigma (X_k : k \leq m \lor k \geq j)$.

Non-singularity of covariance matrices implies that all random variables $X_n$ are non-degenerate and there is no loss of generality in assuming that $\mathbb{E} X_k = 0$ and $\mathbb{E} X_k^2 = 1$ for all $k \in \mathbb{Z}$, which implies $b = 0$. 
It has been shown in [7] that (2.1) implies $L_2$-stationarity (stationarity in the wider sense) of $X$. Since the case $\rho := \text{corr}(X_0, X_1) = 0$ contains sequences of independent random variables (which satisfy (2.1) and (2.2) but can have arbitrary distributions), we shall exclude it from the considerations. Observe that non-singularity of the covariance matrices implies $|\rho| < 1$. By Theorem 3.1 from [1] (see also Theorems 1 and 2 in [7]), we have $\text{corr}(X_0, X_k) = \rho^{|k|}$. Moreover the one-sided regressions are linear

$$\mathbb{E}(X_m|\mathcal{F}_0) = \rho^m X_0 = \mathbb{E}(X_{-m}|\mathcal{F}_0) \quad m \geq 1.$$  

It turns out that parameters $a, \rho, A, B, C$ are related to one another. In [1] and [8] it was shown that one can redefine parameters by introducing new parameter $q = \frac{\rho^{2n} + (\rho + \frac{1}{\rho})^2 - 1}{1 + \rho^2 (\rho + \frac{1}{\rho})^2 - 1}$ and express parameters $A, B, C$ with the help of $\rho$ and $q$ only in the following manner:

$$A = \frac{\rho^2 (1 - q \rho^2)}{(\rho^2 + 1)(1 - q \rho^2)}, B = \frac{\rho^2 (1 - \rho^2)(1 + q)}{(\rho^2 + 1)(1 - q \rho^2)}, C = \frac{(1 - \rho^2)^2}{1 - q \rho^2}.$$  

We can rephrase and summarize the results of [1] and [7] in the following way. Each 1TSP is characterized by two parameters $\rho$ and $q$. For $q$ outside the set $[-1, 1] \cup \{1/\rho^{2n} : n \in \mathbb{N}\}$ 1TSP’s do not exist. For $0 < |\rho| < 1$ and $q \in [-1, 1]$ 1TSP’s exist and all their finite dimensional distribution are uniquely determined and known. Also it follows from [1] and [2] that 1TSP are Markov processes. The case $0 < |\rho| < 1$ and $q \in \{1/\rho^{2n} : n \in \mathbb{N}\}$ is treated in [14].

1TSP with $0 < |\rho| < 1$ and $q \in (-1, 1]$ we will call regular.

We adopt notation traditionally used in 'q-series theory': $(a; q)_0 = 1,$

$$(a; q)_n = \prod_{i=0}^{n-1} (1 - a q^i), (a_1, \ldots, a_k; q)_n = \prod_{i=1}^{k} (a_i; q)_n,$$  

$[0]_q = 0, [n]_q = 1 + \ldots + q^{n-1}, n \geq 1, [0]_q! = 1, [n]_q! = \prod_{i=1}^{n} [i]_q,$

$$\begin{bmatrix} n \\ k \end{bmatrix}_q = \begin{cases} [n]_q \begin{pmatrix} n-k \\ k \end{pmatrix}_q & \text{when } 0 \leq k \leq n \\ 0 & \text{when } k > n \end{cases}.$$  

Notice that we have: $(q; q)_n = (1 - q)^n [n]_q!, \begin{bmatrix} n \end{bmatrix}_q = \frac{(q; q)_n}{(q^{-1}; q)_n}$. As it is customary in q-series theory we will often abbreviate $(a; q)_n$ and $(a_1, \ldots, a_k; q)_n$ to $(a)_n$ and $(a_1, \ldots, a_k)_n$ if it will not cause misunderstanding.

To completely recollection of basic properties of 1TSP let us introduce the so called $q$-Hermite polynomials $\{H_n(x|q)\}_{n \geq 1}$ defined by the following recurrence:

$$\forall n \geq 0: x H_n(x|q) = H_{n+1}(x|q) + [n]_q H_{n-1}(x|q),$$  

with $H_{-1}(x|q) = 0, H_0(x|q) = 1$.

**Remark 1.** Comparing initial values and 3-term recurrences (see e.g. [8]) one can easily notice that $\{H_n(x|1)\}_{n \geq 1}$ are the so called probabilistic Hermite polynomials (i.e. orthogonal with respect to the measure with density $\exp(-x^2/2)/\sqrt{2\pi}$), while for $\forall n \geq -1 H_n(x|0) = U_n(x/2)$ where $\{U_n\}$ are the so called Chebyshev polynomials of the second kind i.e. polynomials orthogonal with respect to the measure with density $\sqrt{1-x^2}/\pi$.  

(1) W. Bryc in [1] has shown that there exist stationary distribution of $X$ and that:
\[
\forall n \in \mathbb{Z}, k, i \geq 1 : \mathbb{E} \left( H_k \left( X_n | q \right) \mid \mathcal{F}_{\leq n-i} \right) = \rho^{k+i} H_k \left( X_{n-i} | q \right), \text{ a.s.}
\]
and also that \( \{ H_n \left( x | q \right) \}_{n \geq -1} \) are orthogonal polynomials of the stationary distribution.

The case $q = -1$ is equivalent to $B = 0$ and leads to marginal symmetric distribution concentrated on \( \{-1, 1\} \).

We will concentrate thus on the case $q \in (-1, 1]$.

Let $I_A (x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A \end{cases}$ denote index function of the set $A$ and define also

\[
S(q) = [-2/\sqrt{1-q}, 2/\sqrt{1-q}] : \text{for } q \in (-1, 1) \text{ and } S(1) = \mathbb{R}.
\]

It turns out that the stationary distribution of $1TSP$ has for $q \in (-1, 1)$ the density given by

\[
f_N (x | q) = \frac{\sqrt{1-q} (\rho^q)^\infty}{2 \pi \sqrt{4 - (1-q)x^2}} \prod_{k=0}^{\infty} \left( (1 + q^k)^2 - (1-q)x^2 q^k \right) I_{S(q)} (x),
\]

while for $q = 1$ it is equal to

\[
f_N (x | 1) = \frac{1}{\sqrt{2 \pi}} \exp \left( -\frac{x^2}{2} \right), \quad x \in \mathbb{R},
\]

In particular for $q = 0$ we have

\[
f_N (x | 0) = \frac{\sqrt{4 - x^2}}{2 \pi}.
\]

W. Bryc in [1] has also found the density of the conditional distribution $X_n | X_{n-1} = y$ and later W. Bryc, W. Matysiak and P. J. Szabowski in [3] have found orthogonal polynomials of this conditional distribution. Namely it turned out that this distribution has for $q \in (-1, 1)$ and $y \in S(q)$ density of the form

\[
f_{CN} (x | y, \rho, q) = \frac{\sqrt{1-q} (\rho^y q)^\infty}{2 \pi \sqrt{4 - (1-q)x^2}} \prod_{k=0}^{\infty} \left( (1 + q^k)^2 - (1-q)x^2 q^k \right) I_{S(q)} (x),
\]

and that polynomials $\{ P_n (x | y, \rho, q) \}_{n \geq -1}$ defined by

\[
\forall n \geq 0 : P_{n+1} (x | y, q, \rho) = (x - \rho q^n) P_n (x | y, q, \rho) - (1 - \rho^2 q^{n-1}) [n]_q P_{n-1} (x | y, q, \rho),
\]

with $P_{-1} (x | y, q, \rho) = 0$, $P_0 (x | y, q, \rho) = 1$, are orthogonal with respect to the measure defined by the density (2.9). We will call polynomials $\{ P_n \}$ Al-Salam–Chihara (briefly ASC).

To support intuition let us notice that both densities $f_N$ and $f_{CN}$ are bounded. More precisely we have the following easy remark giving bounds for the both considered densities. Let us remark also that in [18] are presented bounds for $f_N$ more subtle than the ones given below.
Lemma 1. There are many proofs of these simple facts. One of the simplest can be

\[
\int_{S(q)} H_n(x|q) H_m(x|q) f_N(x|q) \, dx = \begin{cases} 
0 & \text{when } n \neq m \\
\frac{1}{[n]_q}! & \text{when } n = m
\end{cases}.
\]

Proof. i) Follows the fact that for \( x \in S(q) \) : \( (1 + q^k)^2 - (1 - q)x^2q^k \leq (1 + |q|^k) \) and \( \sqrt{4 - x^2} \leq 2 \). ii) was proved in [16] Proposition 1.vii.

Again we have two special simple cases presented in the following remark.

Remark 2. i) For \( |q| < 1 \), \( \forall x \in S(q) : f_N(x|q) \leq \frac{\sqrt{1 - q^2}}{\pi} (q|q)_\infty (-|q|)^2 \), and

\[
f_N\left(\frac{1+q}{\sqrt{1-q}}|q\right) = 0,
\]

ii) For \( |q| < 1 \), \( \forall x, y \in S(q) : 0 < C(y, \rho, q) \leq \frac{f_{CN}(x|y, \rho, q)}{f_N(x|q)} \leq \frac{(\rho^2)_\infty}{(\rho)_\infty}.
\]

Proof. i) Follows the fact that for \( x \in S(q) \) : \((1 + q^k)^2 - (1 - q)x^2q^k \leq (1 + |q|^k) \) and \( \sqrt{4 - x^2} \leq 2 \). ii) was proved in [16] Proposition 1.vii.

We will need several properties of polynomials \( \{H_n\} \) and \( \{P_n\} \). Most of these properties can be found in [3] and some in [3]. We will collect these properties in the following Lemma.

Lemma 1. Assume \( |q| < 1 \). i) For \( n, m \geq 0 \):

\[
\int_{S(q)} H_n(x|q) H_m(x|q) f_N(x|q) \, dx = \begin{cases} 
0 & \text{when } n \neq m \\
\frac{1}{[n]_q}! & \text{when } n = m
\end{cases}.
\]

ii) For \( n \geq 0 \):

\[
\int_{S(q)} H_n(x|q) f_{CN}(x|y, \rho, q) \, dx = \rho^n H_n(y|q),
\]

iii) For \( n, m \geq 0 \):

\[
\int_{S(q)} P_n(x|y, \rho, q) P_m(x|y, \rho, q) f_{CN}(x|y, \rho, q) \, dx = \begin{cases} 
0 & \text{when } n \neq m \\
\frac{1}{[n]_q}! \rho^n[n]_q & \text{when } n = m
\end{cases}.
\]

iv) For \( (1-q)x^2 \leq 4 \) and \( \forall (1-q)t^2 < 1 \):

\[
\int_{S(q)} f_{CN}(x|y, \rho_1, q) f_{CN}(y|z, \rho_2, q) \, dy = f_{CN}(x|z, \rho_1 \rho_2, q).
\]

v) \( \max_{x \in S(q)} |H_n(x|q)| \leq W_n(q) / (1-q)^{n/2} \), where \( W_n(q) = \sum_{i=0}^{n} [n]_q \).

vi) \( \sum_{i=0}^{\infty} W_n(q) t^i = \frac{1}{(1-q)} \) and \( \sum_{i=0}^{\infty} W_n(q) t^i = \frac{(t^2)}{(1-q)} \) absolutely for \( |t|, |q| < 1 \),

where \( W_i(q) \) is defined in v).

vii) For \( (1-q)x^2 \leq 4 \) and \( \forall (1-q)t^2 < 1 \):

\[
\varphi(x, t|q) = \frac{1}{[n]_q}! H_n(x|q) = \prod_{k=0}^{\infty} \left( 1 - (1 - q)x^2q^{2k} \right)^{-1},
\]

convergence is absolute and uniform in \( x \). Moreover \( \varphi(x, t|q) \) is nonnegative and

\[
\int_{S(q)} \varphi(x, t|q) f_N(x|q) \, dx = 1.
\]

viii) For \( (1-q) \max(x^2, y^2) \leq 4 \), \( |q| < 1 \) and \( \forall (1-q)t^2 < 1 \):

\[
\tau(x, t|y, \rho, q) = \sum_{i=0}^{\infty} \frac{t^i}{[n]_q} P_n(x|y, \rho, q) = \prod_{k=0}^{\infty} \left( 1 - (1 - q)x^2q^{2k} \right)^{-1},
\]

where \( \varphi(x, t|q) \) is nonnegative and

\[
\int_{S(q)} \varphi(x, t|q) f_N(x|q) \, dx = 1.
\]

viii) For \( (1-q) \max(x^2, y^2) \leq 4 \), \( |q| < 1 \) and \( \forall (1-q)t^2 < 1 \):

\[
\tau(x, t|y, \rho, q) = \sum_{i=0}^{\infty} \frac{t^i}{[n]_q} P_n(x|y, \rho, q) = \prod_{k=0}^{\infty} \left( 1 - (1 - q)x^2q^{2k} \right)^{-1},
\]
convergence is absolute and uniform in \( x \). Moreover \( \tau (x, t | \theta, \rho, q) \) is nonnegative and \( \int_{\mathbb{R}} \tau (x, t | y, \rho, q) f_{CN} (x | y, \rho, q) \, dx = 1 \).

ix) For \((1 - q) \max (x^2, y^2) \leq 2, \, |\rho| < 1\)

\[
f_{CN} (x | y, \rho, q) = f_N (x | q) \sum_{n=0}^{\infty} \frac{\rho^n}{n!} H_n (x | q) H_n (y | q)
\]

and convergence is absolute and uniform in \( x \) and \( y \).

**Proof.** Since the more popular are slightly modified polynomials \( H_n \) namely polynomials \( h_n (x | q) = H_n \left( \frac{x}{\sqrt{1-q}} | q \right) / (1-q)^{n/2}; \, x \in [-1,1] \) (called continuous \( q \)-Hermite polynomials) and \( p_n (x | y, \rho, q) = P_n \left( \frac{2x}{\sqrt{1-q}} | \sqrt{\frac{2q}{1-q}}; \, \rho, q \right) \), many properties of \( q \)-Hermite and Al-Salam–Chi̇hara polynomials are formulated in terms of \( h_n \) and \( p_n \). i) It is formula 13.1.11 of [3] with an obvious modification for the polynomials \( H_n \) instead of \( h_n \) and normalized weight function (i.e. \( f_N \)) ii) Exercise 15.7 of [5] also in [1], iii) Formula 15.15 of [5] with obvious modification for polynomials \( p_n \) instead of \( P_n \) and normalized weight function (i.e. \( f_{CN} \)), iv) see (2.6) of [3], v) and vi) Exercise 12.2(b) and 12.2(c) of [3], vii)-viii) follow v) and vi). Besides non-negativity of \( \varphi \) and \( \tau \) are trivial and follow formulae \( 1 - (1-q) x t q^k + (1-q) t q^2 k = (1-q)(t q^k - x / 2)^2 + 1 - (1-q) x^2 / 4 \) and \( 1 - (1-q) \rho y t q^k + (1-q) \rho^2 t^2 q^2 k = (1-q)\rho^2(q^k t - y/(2\rho))^2 + 1 - (1-q) y^2 / 4. \) Values of integrals follow i) and iii). ix) is the famous Poisson–Mehler expansion formula. It has many proofs presented e.g. in [5], [3], [17].

Two special cases \( q = 0,1 \) are treated in the following Remark.

**Remark 4.** Assertions i)-iv) and ix) of the Lemma[4] are true also for \( q = 1 \). This follows elementary properties of Hermite polynomials exposed e.g. in [6]. Further we have

\[
\varphi (x, t | 1) = \exp (xt - t^2/2), \varphi (x, t | 0) = \frac{1}{1 - xt + t^2},
\]

\[
\tau (x, t | y, \rho, 1) = \exp (t (x - \rho y) - t^2(1-\rho^2)/2) \quad \tau (x, t | y, \rho, 0) = \frac{(1-\rho yt + \rho^2 t^2)}{(1-xt + t^2)}.
\]

For \( q = 1 \) we have

\[
f_{CN} (x | y, \rho, 1) = \frac{1}{\sqrt{2\pi(1-\rho^2)}} \exp \left( -\frac{(x - \rho y)^2}{2(1-\rho^2)} \right),
\]

(i.e. Normal \( N(\rho y, 1 - \rho^2) \) distribution) while for \( q = 0 \) we have

\[
f_{CN} (x | y, \rho, 0) = \frac{(1-\rho^2) \sqrt{4-x^2}}{2\pi((1-\rho)^2 - \rho(1+\rho^2)xy + \rho^2(x^2 + y^2))},
\]

\( x, y \in [-2,2], \, |\rho| < 1, \) -the so called Kesten–McKay distribution.

As mentioned earlier we are going to consider continuous time generalization of the process \( \mathbf{X} \) considered in this section. Namely, more precisely, we are going to prove the existence and present basic properties of the process \( \mathbf{Y} = \{Y_t\}_{t \in \mathbb{R}} \), satisfying the following condition:
Lemma 2. Let \( \{X_i\}_{i \in \mathbb{Z}} \) 1TSP with parameters \( \rho \) and \( q \). Let us fix \( j \in \mathbb{N} \) and \( m \in \{0, \ldots, j-1\} \) and define \( Z_k = X_{kj+m} \) for \( k \in \mathbb{Z} \). Then \( \{Z_k\}_{k \in \mathbb{Z}} \) is also 1TSP with parameters \( \rho^j \) and \( q \).

To do this we need generalizations of properties (2.1) and (2.2). They are given in Proposition presented below. On the other hand this Proposition needs the following technical Lemma.

Lemma 3. If \( X \) is a 1TSP then:

\[
\begin{align*}
(3.1a) \quad & \mathbb{E}X_n^4 = (2 + q), \\
(3.1b) \quad & \mathbb{E}X_n^2X_m^2 = 1 + \rho^{2|n-m|}(1 + q), \\
(3.1c) \quad & \mathbb{E}X_n^2X_{n-j}X_{n+k} = \rho^j \mathbb{E}X_n^4 = \rho^j(2 + q).
\end{align*}
\]

Proposition 1. If \( X \) is a 1TSP then for \( n, j, k \in \mathbb{N} \)

i) \( \mathbb{E}(X_n|\mathcal{F}_{\leq n-j, \geq n+k}) \) is a linear function of \( X_{n-k} \) and \( X_{n+j} \). More precisely we have

\[
(3.2) \quad \mathbb{E}(X_n|\mathcal{F}_{\leq n-k, \geq n+j}) = \frac{\rho^j(1 - \rho^{2k})}{1 - \rho^{2(j+k)}}X_{n-j} + \frac{\rho^k(1 - \rho^{2j})}{1 - \rho^{2(j+k)}}X_{n+k}.
\]

ii) \( \mathbb{E}(X_n^2|\mathcal{F}_{n-j, \geq n+k}) \) is a linear function of \( X_{n-j}^2 \), \( X_{n+k}^2 \), \( X_{n-j}X_{n+k} \). In particular

\[
(3.3) \quad \mathbb{E}(X_n^2|\mathcal{F}_{\leq n-j, \geq n+k}) = A_{jk}^{(1)}X_{n-j}^2 + A_{jk}^{(2)}X_{n+k}^2 + B_{jk}X_{n-j}X_{n+k} + C_{jk}
\]

where:

\[
\begin{align*}
(3.4a) \quad & A_{jk}^{(1)} = \frac{\rho^{2j}(1 - \rho^{2k})(1 - q\rho^{2j})}{(1 - q\rho^{2(j+k)})(1 - \rho^{2(j+k)})}, \\
(3.4b) \quad & A_{jk}^{(2)} = \frac{\rho^{2k}(1 - \rho^{2j})(1 - q\rho^{2j})}{(1 - q\rho^{2(j+k)})(1 - \rho^{2(j+k)})}, \\
(3.4c) \quad & B_{jk} = \frac{(q + 1)\rho^{(j+k)}(1 - \rho^{2j})(1 - \rho^{2k})}{(1 - q\rho^{2(j+k)})(1 - \rho^{2(j+k)})}, \\
(3.4d) \quad & C_{jk} = \frac{(1 - \rho^{2j})(1 - \rho^{2k})}{1 - q\rho^{2(j+k)}}.
\end{align*}
\]

Lengthy proofs of these facts as well as the proof of Lemma 2 are moved to section 6.
4. $(\alpha, q)$—Ornstein–Uhlenbeck and $q$–Wiener Processes

4.1. Existence. In this subsection we are going to prove the following Theorem.

**Theorem 1.** The $L_2$–continuous and stationary process $Y = \{Y_t\}_{t \in \mathbb{R}}$ that satisfies for every $\delta > 0$ Condition (4), exists. Moreover there exist two numbers $q \in (-1, 1]$ and $\alpha > 0$ such that $Y$ is Markov with the marginals having density $f_N(x|q)$ and the transition distribution having density $f_{CN}(x|y, e^{-\alpha(s-t)|q})$ (i.e. $Y_s|Y_t = y \sim f_{CN}(x|y, e^{-\alpha(s-t)|q})$)

Proof. An easy but long proof is shifted to Section 6.

In the sequel, when considering the continuous time generalizations of 1TSP we will need the following generalization of ‘non-singularity of covariance matrix’ assumption considered in the case of 1TSP: Let $X = (X_t)_{t \in \mathbb{R}}$ be square integrable stochastic process and

(4.1)

$\forall n \in \mathbb{N}; 0 \leq t_1 < t_2 < \ldots < t_n$ random variables $X_{t_1}, \ldots, X_{t_n}$ are linearly independent which we will also refer to as linear independence assumption be satisfied by $X$.

4.2. $(\alpha, q)$–OU processes. Process $Y$ with parameters $(\alpha, q)$ will be called continuous time $(\alpha, q)$–OU-process. (OU standing for Ornstein–Uhlenbeck). Let us summarize what properties of $Y$ can be deduced from the properties of the discrete time regular 1TSP processes presented in [1], [2], [7], [8], [3] and [15] (Corollary 6 p.13). Some of these properties also appeared in [20] as a by-product of considering some noncommutative model or in [15] in quadratic harnesses context. Hence some of the properties of are not new but they are scattered in the literature and we bring them together and collect in groups devoted to particular features of analyzed processes.

As before let us define the following $\sigma$–fields defined by $Y$. $F_{\leq s} := \sigma (X_t : t \leq s)$, $F_{\geq s} := \sigma (X_t : t \geq s)$, and $F_{s \leq \tau \geq t} := \sigma (X_t : \tau \leq s \vee \tau \geq t)$ for $s < t$.

Theorem below describes marginal and conditional distributions, presents polynomials that are orthogonal with respect to these distributions as well as gives conditional moments with respect to one-sided ($F_{\leq s}$ and $F_{\geq s}$) and two-sided ($F_{s \leq \tau \geq t}$) $\sigma$–fields.

**Theorem 2.** Let $Y$ be a continuous time $(\alpha, q)$–OU–process, $-1 < q \leq 1$, $\alpha > 0$. Then its state space is $S(q)$ and:

(1)

$\forall t \in \mathbb{R} : Y_t \sim f_N(x|q)$,

$\forall s > t : Y_s|Y_t = y \sim f_{CN}(x|y, e^{-\alpha(s-t)|q})$.

(2) $Y$ is a stationary Markov process with $f_{CN}(x|y, e^{-\alpha(s-t)|q})$ as the density of its transition probability.

(3) $Y$ is time symmetric. Moreover we have for any $n \in \mathbb{N}, s \in \mathbb{R}$ and $\delta, \gamma > 0$:

(4.2)

$\mathbb{E} (H_n(Y_s) | F_{s-\delta, s+\gamma}) = \sum_{r=0}^{[n/2]} \sum_{l=0}^{n-2r} A_{r, [n/2]+r+l} (Y_s-\delta|q) H_{n-2r-l}(Y_{s+\gamma}|q)$,

$1 L_2$–continuous means mean-square continuous
where \( \frac{\alpha + 2}{\alpha} \) constants \( A_{r,m}^{(n)} \): \( r = 0, \ldots, \lfloor n/2 \rfloor \), \( m = -\lfloor n/2 \rfloor + r, \ldots, -\lfloor n/2 \rfloor + r + n - 2r \), depend only on \( n, q, e^{-\alpha t} \) and \( e^{-\alpha \gamma} \). 

(4) Families of polynomials \( \{H_n(x|q)\}_{n \geq 0} \) and \( \{P_n(x|y,e^{-\alpha|x-t|},q)\}_{n \geq 0} \) given respectively by (2.7) and (2.10), are orthogonal polynomials of distributions defined by (2.7) and (2.9) respectively. That is in particular we have

\[
\begin{align*}
(4.3) \quad & \forall n \geq 1, t \in \mathbb{R} : EH_n(Y_t|q) = 0 \\
(4.4) \quad & \forall n \geq 1, s > t : E \left[ P_n(Y_s|Y_t,e^{-\alpha(s-t)},q) \mid \mathcal{F}_{\leq t} \right] = 0 \text{ a.s. ,} \\
(4.5) \quad & \forall n \geq 1, s > t : E[H_n(Y_s|q) \mid \mathcal{F}_{\leq t}] = e^{-n\alpha(s-t)}H_n(Y_t|q) \text{ a.s. .}
\end{align*}
\]

(6) \( \forall n \geq 1 : (H_n(Y_t|q))_{t \in \mathbb{R}} \) is a stationary random process with covariance function

\[
K_n(s,t) = [n]!q^{n/2}e^{-n\alpha|s-t|}
\]

and

\[
S_n(\omega|\alpha) = \frac{2n\alpha [n]_q^!}{\omega^2 + n^2\alpha^2},
\]

as its spectral density.

Remarks concerning the proof. (1) and (2) are given in [1] and [3]. (3) is given in [5] (Corollary 5), (4) \( \text{[4.3]} \) is given in [5] (but also in [1]) and (4.4) is given in [3]. (5) is given in [1] \( \text{(6)} \) Notice that from (5) it follows that \( \forall n, m \geq 1, s, t \in \mathbb{R} : EH_m(Y_s|q)H_n(Y_t|q) = \delta_{[n-m]}e^{-n\alpha|x-t|}[EH_n(Y_t|q) = \delta_{[n-m]}e^{-n\alpha|x-t|} [n]_q^!], \) since \( EH_n^2(Y_t|q) = [n]_q^! \), by Lemma [1] (i). Further we use spectral decomposition theorem.

Remark 5. As an immediate consequence of the assertion 1. of the above mentioned theorem we see that if \( Y \) is a certain \((\alpha,q)\)-OU process then the process \( Z \) defined by re-scaling time in the following way \( Z_s = Y_{\alpha s}, s \in \mathbb{R} \) is \((1,q)\)-OU process.

Remark 6. As it follows from Theorem [2] 4. the \((\alpha,q)\)-OU process is stationary and time homogenous. Thus its transition operator is defined by

\[
P_{s,t}(f) (y) = \int_{S(q)} f(x) f_{CN} \left(x|y,e^{-\alpha(t-s)},q\right) dx
\]

for a function \( f \) defined below and \( t > s \) depends in fact on \( t - s = \tau \). Let us define

\[
P^\tau(\cdot) = P_{t,t+\tau}(\cdot).
\]

Operators \( \{P^\tau\}_{\tau \geq 0} \) form a semigroup of operators as it follows from Lemma [7] iv.

As conclusions of assertions of Theorem [2] we have the following Theorem that contains their implications to the Markovian properties of the process \( Y \).

Before we formulate appropriate theorem we need to introduce some additional notation.

Since the paper was written and submitted the exact form of coefficients \( A_{r,m}^{(n)} \) can be derived from the result presented in [10]. Thm. 2 following observation that the conditional distribution of \( X_\sigma \) given \( X_{\sigma-\delta} \), \( X_{\sigma+\gamma} \) has Askey-Wilson density with specific complex parameters.
Corollary 1. Let \(B(q) = L_2(S(q), \mathcal{B}(S(q)), P_N(q))\), where \(\mathcal{B}(S(q))\) denotes \(\sigma\)-field of Borel subsets of \(S(q)\) and \(P_N(q)\) denotes measure with density \(f_N(.)|q\). Obviously we have

\[
B(q) = \left\{ f : S(q) \rightarrow S(q) : f(x) = \sum_{j=0}^{\infty} \frac{b_j}{\sqrt{|j|}_q} H_j(x|q) : \sum_{j \geq 0} |b_j|^2 < \infty \right\}.
\]

Let us further denote:

\[
B^0(q) = \{ f \in B(q) : f(x) = \sum_{j=0}^{\infty} \frac{b_j}{\sqrt{|j|}_q} H_j(x|q) : \sum_{j \geq 0} j^2 |b_j|^2 < \infty \}.
\]

We have \(B^0(q) \subset B(q)\).

Let \(A\) denote infinitesimal operator of the \((\alpha, q)\)-OU process.

**Theorem 3.** Let \(Y\) be \((\alpha, q)\)-OU process with \(|q| < 1\). Then:

i) \(\text{var}(Y_t) = 1\), and for \(s \geq 0\), \(\text{var}(Y_{t+s}|Y_t) = 1 - e^{-2\alpha s}\). Hence in particular trajectories of \((\alpha, q)\)-OU process are càdlàg functions with values in \(S(q)\).

ii) transition operator \(P^\tau\) for \(\tau > 0\) is defined by the following relationship

\[
B(q) \ni f(x) = \sum_{j \geq 0} \frac{b_j}{\sqrt{|j|}_q} H_j(x|q) \rightarrow P^\tau(f)(x) = \sum_{j \geq 0} e^{-\alpha \tau j} \frac{b_j}{\sqrt{|j|}_q} H_j(x|q),
\]

iii) the family of transitional probabilities \(\{P^\tau\}_{\tau > 0}\) is Feller-continuous. In particular process \(Y\) has strong Markov property.

iv) the family \(\{P^\tau\}_{\tau > 0}\) is right continuous consequently process \(Y\) is a Feller process. Moreover its infinitesimal operator \(A\) exists and is defined on a subset \(B^0\) by the following formula:

\[
B^0(q) \ni f(x) = \sum_{j \geq 0} \frac{b_j}{\sqrt{|j|}_q} H_j(x|q) \rightarrow A(f)(x) = -\alpha \sum_{j \geq 1} \frac{j b_j}{\sqrt{|j|}_q} H_j(x|q) \in B(q).
\]

**Proof.** The proof is shifted to section 6.

**Remark 7.** Let us remark that recently Anshelevich in [22] (Lemma 20) expressed the infinitesimal operator in an integral form. To be precise he expressed in this form the infinitesimal operator of the so called \(q\)-Wiener (\(q\)-Brownian motion as he calls it) process to be considered in the next subsection and related to \((\alpha, q)\)-OU by the continuous transformation \((4.9)\).

The detailed forms of constants \(A_{n,m}^{(n)}\) defined by \((4.5)\) are given below following Corollary 6 of [15].

**Corollary 1.** \(A_{0,n-[n/2]+1}^{(n)} = [\frac{n}{l}] q e^{-\alpha (\delta + \gamma)} A_{0,[n/2]+t}^{(n)}, l = 0, \ldots, n, n = 1, \ldots, 4.\) If \(n \leq 3\) then \(A_{1,-[n/2]+t}^{(n)} = -[n-1] q e^{-\alpha (\delta + \gamma)} A_{0,-[n/2]+t}^{(n)}, l = 1, \ldots, n-1,\) \(l \geq 1\) and \(A_{1,0}^{(n)} = -[2]_q e^{-\alpha (\delta + \gamma)} A_{0,0}^{(n)}\), \(A_{2,0}^{(4)} = q(1+q) q e^{-2\alpha (\delta + \gamma)} A_{0,0}^{(4)}\).
In particular we obtain known (see e.g. [9]) formula

\[(4.7) \quad \text{var}(Y_s|\mathcal{F}_{s-\delta, s+\gamma}) = \frac{(1 - e^{-2\alpha\delta})(1 - e^{-2\delta\gamma})}{(1 - q e^{-2\alpha(\delta+\gamma)})}
\]

\[(4.8) \quad \times (1 - \frac{1 - q}{(1 - q) (X_{t-1} - e^{-\alpha(\delta+\gamma)} X_{t+1}) (X_t - e^{-\alpha(\delta+\gamma)} X_{t-1})}).
\]

Following assertion vii of Lemma 1 and we can express assertion Theorem 5 (5) in the following martingale-like form.

**Theorem 4.** For \(|q| < 1\) we have

\[\forall \gamma^2 (1 - q), s > t : \mathbb{E}(\varphi(Y_s, \gamma|q)|\mathcal{F}_{s+t}) = \varphi(Y_t, \gamma e^{-\alpha(s-t)}|q) \quad \text{a.s.}\]

where positive function \(\varphi\) is defined in Lemma 1 vii).

In particular for \(q = 0\) (so called free \(\alpha-\text{OU-process}\)) we have

\[\forall |\gamma| < 1, s > t : \mathbb{E}\left(\frac{1}{1 - \gamma Y_s + \gamma^2}|\mathcal{F}_{s+t}\right) = \frac{1}{1 - \gamma e^{-\alpha(t-s)} Y_t + \gamma^2 e^{-2\alpha(t-s)}} \quad \text{a.s.,}
\]

while for \(q = 1\) we get well known formula:

\[\forall \gamma \in \mathbb{R}, s > t : \mathbb{E}\left(\exp(\gamma Y_s - \gamma^2/2)|\mathcal{F}_{s+t}\right)
= \exp\left(\gamma e^{-\alpha(s-t)} Y_t - \left(\gamma e^{-\alpha(s-t)}\right)^2/2\right) \quad \text{a.s.}
\]

Strict proof is very much alike the proof of Corollary 4 below, so we will not present it here.

**Remark 8.** Notice that following considerations of the section 2 concerning existence of \((\alpha, q) - \text{OU process}\) one needed only the following two, symmetric in time, conditions apart from linear independence:

1. \(\forall n \in \mathbb{Z}, d > 0:\)
\[
\mathbb{E}\left(Y_{nd}|\mathcal{F}_{s-(n-1)d, s+(n+1)d}\right) = \frac{e^{-\alpha d}}{1 + e^{-2\alpha d}} (Y_{(n-1)d} + Y_{(n+1)d}),
\]

2. \(\forall n \in \mathbb{Z}, d > 0:\)
\[
\mathbb{E}\left(Y_{nd}^2|\mathcal{F}_{s-(n-1)d, s+(n+1)d}\right) = \hat{A} \left(Y_{(n-1)d}^2 + Y_{(n+1)d}^2\right) + \hat{B} Y_{(n-1)d} Y_{(n+1)d} + \hat{C},
\]

where \(\hat{A} = A_1(d, d), \hat{A} = A_2(d, d), \hat{B} = B(d, d), \hat{C} = C(d, d).\) That is we need only symmetric (and discrete for all increments \(d > 0\)) versions of condition defining \(\mathbb{E}(Y_{nd}^2|\mathcal{F}_{s-\delta, s+\gamma}).\)

**Remark 9.** Notice that continuous time \((\alpha, q) - \text{OU process}\) does not exist for \(q > 1.\) It is so because for discrete time 1TSP with parameters \((q, \rho)\) the following relationship between parameters \(q\) and \(\rho\) must be satisfied for some integer \(n : \rho^2 q^n = 1\) or equivalently ratio \(\frac{\log q}{\log \rho}\) must be equal to some integer. However if \((\alpha, q) - \text{OU process}\) exist one needed only the following condition defining \(\rho = \exp(-2\alpha t)\) for some fixed positive \(\alpha\) and consequently \(\frac{\log q}{\log \rho}\) would have to be integer for all real \(t\) which is impossible.
4.3. \(q\)-Wiener process. Let \(Y\) be given \((\alpha,q)\)-OU process. Let us define:

\[
X_0 = 0; \ \forall \tau > 0 : X_\tau = \sqrt{\tau}Y_{\log\tau/2\alpha}.
\]

Process \(X = (X_\tau)_{\tau \geq 0}\) will be called \(q\)-Wiener process. Let us also introduce the following filtration:

\[
\mathcal{F}^X_{\leq \theta} = \sigma(X_\tau : \tau \leq \theta) = \sigma(Y_t : t \leq \log\theta/2\alpha) \ (= \mathcal{F}^{\log\theta/2\alpha}_{\leq \theta}).
\]

Remark 10. From (4.9) and from the properties of \((\alpha,q)\)-OU process it follows that \(X\) is a self-similar process since for \(c > 0\) we see that \(\{Z_\tau\}_{\tau \geq 0}\) where \(Z_\tau = c^{-1}X_{c^2\tau}; \ \tau \geq 0\), is also a \(q\)-Wiener process.

Following definition given by (4.9) and Theorem 2 of the previous section we have the following Theorem whose detailed proof is simple but lengthy and thus is shifted to section 6.

**Theorem 5.** Let \(X\) be a \(q\)-Wiener process, then it has the following properties:

1. \(\forall \tau, \sigma \geq 0 : \text{cov}(X_\tau, X_\sigma) = \min(\tau, \sigma)
\]
2. \(\forall \tau > 0 : X_\tau \sim \sqrt{\frac{1}{\tau}} f_{\text{CN}}(\frac{X_\tau}{\sqrt{\tau}}, q).
\]
3. For \(\tau > \sigma : X_\tau - X_\sigma | X_\sigma = y \sim \sqrt{\frac{1}{\tau}} f_{\text{CN}}(\frac{y + y}{\sqrt{\sigma}}, \sqrt{\tau}, q).
\]
4. For all \(n \geq 1\) and \(0 < \alpha \leq \tau\) we have

\[
E \left( \tau^{n/2} H_n \left( \frac{X_\tau}{\sqrt{\tau}} | q \right) | \mathcal{F}^{X}_{\leq \tau} \right) = \sigma^{n/2} H_n \left( \frac{X_\sigma}{\sqrt{\sigma}} | q \right) \text{ a.s.},
\]

\[
E \left( \sigma^{-n/2} H_n \left( \frac{X_\sigma}{\sqrt{\sigma}} | q \right) | \mathcal{F}^{X}_{\geq \tau} \right) = \tau^{-n/2} H_n \left( \frac{X_\tau}{\sqrt{\tau}} | q \right) \text{ a.s.}.
\]

Hence \(\forall n \geq 1\) the pair \((Z^{(n)}_\tau, \mathcal{F}^{X}_{\leq \tau})_{\tau \geq 0}\), where \(Z^{(n)}_\tau = \tau^{n/2} H_n (X_\tau/\sqrt{\tau} | q)\), \(\tau \geq 0\) is a martingale and the pair \((V^{(n)}_\tau, \mathcal{F}^{X}_{\geq \tau})_{\tau \geq 0}\), where \(V^{(n)}_\tau = \tau^{-n/2} H_n (\frac{X_\tau}{\sqrt{\tau}} | q)\) is the reverse martingale. In particular \(X\) is a martingale and \((\frac{X_\tau}{\sqrt{\tau}}, \mathcal{F}^{X}_{\geq \tau})_{\tau \geq 0}\) is the reversed martingale.

5. We have also \(\forall n \geq 1, \delta, \gamma \geq 0, \sigma \geq \delta
\]

\[
E \left( H_n \left( \frac{X_\sigma}{\sqrt{\sigma}} | q \right) | \mathcal{F}_{\leq \sigma - \delta, \geq \sigma + \gamma} \right) = \sum_{r = 0}^{\lfloor n/2 \rfloor} \sum_{l = 0}^{n - 2r} A^{(n)}_{r, l - \lfloor n/2 \rfloor + r + l} H_l \left( \frac{X_\sigma - \delta}{\sqrt{\sigma - \delta}} | q \right) H_{n - 2r - l} \left( \frac{X_{\sigma + \gamma}}{\sqrt{\sigma + \gamma}} | q \right),
\]

where \(\lfloor \frac{n+1}{2} \rfloor \lfloor \frac{n+3}{2} \rfloor \) constants \(A^{(n)}_{r,s}\); \(r = 0, \ldots, \lfloor n/2 \rfloor\), \(s = -\lfloor n/2 \rfloor + r, \ldots, -\lfloor n/2 \rfloor + r + n - 2r\) depend only on \(n, q\), and numbers \(\sigma, \delta\) and \(\gamma\).

We have the following immediate, easy observation.

**Remark 11.** From assertion 2 of the above mentioned Theorem we see that for every \(t > 0\), \(tX_{1/t}\) and \(X_1\) have the same distribution.

**Corollary 2.** Let \(X\) be a \(q\)-Wiener process. We have:

---

\(^3\)See footnote to assertion 3 of Theorem [2]
\( \forall \tau > \sigma > 0 : E \left( (X_\tau - X_\sigma)^2 \middle| F_{\leq \sigma}^X \right) = \tau - \sigma \text{ a.s.} \),
\( \forall \tau > \sigma > 0 : E \left( (X_\tau - X_\sigma)^3 \middle| F_{\leq \sigma}^X \right) = -(1 - q) (\tau - \sigma) X_\sigma \text{ a.s.} \),
\( \forall \tau > \sigma > 0 : E \left( (X_\tau - X_\sigma)^4 \middle| F_{\leq \sigma}^X \right) = (\tau - \sigma) \left( X_\sigma^2 (1 - q)^2 + (2 + q)(\tau - \sigma) + \sigma (1 - q^2) \right) \text{ a.s.} \).

Hence \( X_\tau \geq \tau \) moreover \( X \) does not have independent increments.

ii) Almost every path of process \( X \) has at any point left and right hand side limits, thus can be modified to have càdlàg trajectories.

iii) Process \( X \) is Feller-continuous process and has strong Markov property.

The following corollary gives more detailed consequences of [15] (Corollary 6 p.13). These conditional moments are known of course (see e.g. [13] for limits, thus can be modified to have càdlàg trajectories.

Corollary 3. We have \( A_{n-i}^{(n)} = \frac{\rho_i c_{n-i} a_i c_i}{\rho_i^2 a_i^2} \), \( i = 0, \ldots, n \).

If \( n \leq 3 \) then \( A_{n-i}^{(n)} = -[n - 1] \rho_1 \rho_2 A_{n-i}^{(n)} \), \( i = 1, \ldots, n - 1 \).

If \( n = 4 \) then \( A_{1, j}^{(4)} = -[3] \rho_1 \rho_2 A_{1, j}^{(4)} \), \( j = 1, 1 \) and \( A_{1, 0}^{(4)} = -[2] \rho_1 \rho_2 A_{1, 0}^{(4)} \), \( A_{1, 0}^{(4)} = q(1 + q) \rho_1^2 \rho_2^2 A \), where \( \rho_1 = \sqrt{(\sigma - \delta)/\sigma} \), \( \rho_2 = \sqrt{\sigma/\sigma + \gamma} \). In particular we can deduce the following known (from say [20], [10] or [9]) formulae:

\[
E \left( X_\sigma \middle| F_{\leq \sigma - \delta, \geq \sigma + \gamma} \right) = \frac{\gamma + \delta}{\delta + \gamma} X_{\sigma - \delta} + \frac{\delta}{\delta + \gamma} X_{\sigma + \gamma} \text{ a.s.} ,
\]
\[
E \left( X_\sigma^2 \middle| F_{\leq \sigma - \delta, \geq \sigma + \gamma} \right) = \frac{\delta \gamma}{(\delta + \gamma)(\sigma - (1 - q) + \gamma + q\delta)} \times
\]
\[
\left( (1 - q) (1 + q) \frac{X_{\sigma - \delta}^2}{\delta} + (1 - q) \frac{X_{\sigma + \gamma}^2}{\gamma} + (q + 1) \frac{X_{\sigma - \delta} X_{\sigma + \gamma}}{\delta + \gamma} \right) ,
\]
\[
\text{var} \left( X_\sigma \middle| F_{\leq \sigma - \delta, \geq \sigma + \gamma} \right) = \frac{\delta \gamma}{(\sigma - (1 - q) + \gamma + q\delta)} \times \left( 1 - (1 - q) \frac{(X_{\sigma + \gamma} - X_{\sigma - \delta}) (\delta + \gamma)}{\delta + \gamma} \right) .
\]

Following Theorem [5] we get:

Corollary 4. Let \( X = (X_\tau)_{\tau \geq 0} \) be a \( q \)-Wiener process. \( \forall s \in \mathbb{R}, 0 < \sigma^{-1}, \tau < \frac{1}{s^2 (1 - q)} \), the following pairs:

\[
\left( \varphi \left( \frac{X_{\tau}}{\sqrt{\sigma}}, s \sqrt{\tau} \right), F_{\leq \tau}^X \right)_{1/((1 - q)s^2) > \tau \geq 0},
\]
\[
\left( \varphi \left( \frac{X_{\tau}}{\sqrt{\sigma}}, s \sqrt{\tau} \right), F_{\geq \tau}^X \right)_{\tau > (1 - q)s^2 \geq 0} .
\]
are positive respectively martingale and reversed martingale, where function \( \varphi(x, t|q) \) is a characteristic function of \( q \)-Hermite polynomials and is defined in Lemma [14 v]vii).

In particular we get:

\[
\forall s \in \mathbb{R}, \quad \frac{1}{(1 - q)s^2} > \tau > 0 : \mathbb{E}\left( \varphi\left( \frac{X_{\tau}}{\sqrt{\tau}}, s\sqrt{\tau}|q \right) \right) = 1,
\]

\[
\forall s \in \mathbb{R}, \quad s^2(1 - q) < \tau : \mathbb{E}\left( \varphi\left( \frac{X_{\tau}}{\sqrt{\tau}}, s\sqrt{\tau}|q \right) \right) = 1.
\]

0–Wiener process (sometimes called free Wiener process) satisfies:

\[
\forall s \in \mathbb{R}, 0 < \tau < \sigma < \frac{1}{s^2} : \mathbb{E}\left( \frac{1}{1 - sX_{\tau} + \tau s^2} | \mathcal{F}_{\leq \sigma}^X \right) = \frac{1}{1 - sX_{\tau} + \sigma s^2}; \text{ a.s.}
\]

\[
\forall s \in \mathbb{R}, 0 < s^2 < \sigma < \tau : \mathbb{E}\left( \frac{1}{1 - sX_{\sigma}/\sigma + s^2/\sigma} | \mathcal{F}_{\geq \tau}^X \right) = \frac{1}{1 - sX_{\tau}/\tau + s^2/\tau}; \text{ a.s.}
\]

1–Wiener process satisfies of course

\[
\forall s \in \mathbb{R} : \mathbb{E}\left( \exp\left( sX_{\tau} - \tau s^2/2 \right) | \mathcal{F}_{\leq \sigma}^X \right) = \exp\left( sX_{\sigma} - \sigma s^2/2 \right); \text{ a.s.}
\]

\[
\forall s \in \mathbb{R} : \mathbb{E}\left( \exp\left( sX_{\sigma}/\sigma - s^2/\sigma \right) | \mathcal{F}_{\geq \tau}^X \right) = \exp\left( sX_{\tau}/\tau - s^2/\tau \right); \text{ a.s.}
\]

Remark 12. Let us recall following [13] that quadratic harnesses are roughly speaking square integrable processes \( \{Z_t\}_{t \in \mathbb{R}^+} \) that satisfy 5 conditions imposed on their covariance functions and on the first two conditional moments given the past and given the past and the future. These conditions require that \( \mathbb{E}(Z_t | \mathcal{F}_{\leq \delta}^X) \) and \( \mathbb{E}(Z_t | \mathcal{F}_{\leq \delta, \geq \tau + \gamma}) \) be linear functions while \( \mathbb{E}(Z_t^2 | \mathcal{F}_{\leq \delta}^X) \) and \( \mathbb{E}(Z_t^2 | \mathcal{F}_{\leq \delta, \geq \tau + \gamma}) \) be a quadratic functions of respectively \( Z_{t-\delta} \) and \( Z_{t+\gamma} \). Examining assertion of Corollary [3] we see that \( q \)-Wiener process has this property. Thus we deduce that \( X \) is a quadratic harness with parameters (introduced in [13]) \( \theta = \eta = \tau = \sigma = 0 \).

Remark 13. From Theorem [4] it follows that \( \{X_{\tau}, \mathcal{F}_{\leq \tau}^X\}_{\tau \geq 0}, \{X_{\tau}^2 - \tau, \mathcal{F}_{\leq \tau}^X\}_{\tau \geq 0} \) are martingales and \( \{X_{\tau}/\tau, \mathcal{F}_{\geq \tau}^X\}_{\tau > 0}, \{X_{\tau}^2/\tau^2 - 1/\tau, \mathcal{F}_{\geq \tau}^X\}_{\tau > 0} \) are reversed martingales. Thus if main result of Wesolowski’s paper [19] (stating that a process satisfying these conditions should be a Wiener process) was true we would deduce that \( X \) is the Wiener process. But it is not at least for \( |q| < 1 \). Let us note that Wesolowski is aware of this since in [3] he (together with Bryc) gives examples that contradict the result of [19]. He however did not point out where was the mistake. Recall that Wesolowski considered processes that have the property that they and their squares were both martingales and reversed martingales. Wesolowski’s argument was based on the value \( \mathbb{E}(X_{\tau} - X_{\sigma})^4 \) that had to be calculated for the considered process. Following formulae presented above we deduce that \( \mathbb{E}(X_{\tau} - X_{\sigma})^4 = (2 + q) (\tau - \sigma)^4 + 2(1 - q)\sigma (\tau - \sigma) \) for a \( q \)-Wiener process, while Wesolowski stated that \( \mathbb{E}(X_{\tau} - X_{\sigma})^4 = \gamma (\tau - \sigma)^4 + 2(c - \gamma)\sigma (\sigma + \tau) \), where \( c = \mathbb{E}X^2/\sigma^2 \). In the case of \( q \)-Wiener process one can calculate that \( c = (2 + q) \) thus Wesolowski made mistake in his calculations.
Remark 14. Following (4.12) and (4.13) we have
\[ \forall 0 < \sigma < \tau \leq \nu < \omega : \text{cov} \left( X_\tau - X_\sigma, X_\omega - X_\nu \right) = 0, \]
\[ \text{cov} \left( (X_\tau - X_\sigma)^2, (X_\omega - X_\nu)^2 \right) = 0, \]
\[ \text{cov} \left( (X_\tau - X_\sigma)^3, (X_\omega - X_\nu)^3 \right) = - (1 - q) (\tau - \sigma) (\omega - \nu) (\tau (2 + q) - \sigma (1 + 2q)). \]

5. Open problems

As it follows from the description of \( q \)-Wiener and \((\alpha, q)\)-OU processes they do not allow continuous paths modifications. Their paths have jumps. Besides both left- and right-hand side limits exist at any jumping point. Consequently the paths of these processes do not have discontinuities of the second kind. Thus there are immediate several questions:

(1) In general on every finite interval there can be infinitely many jumps. Is it true? Or can one prove some additional properties of these processes that would eliminate this case? Certainly such properties do not exist for all \(|q| < 1\). The case \( q = 0 \) leads to the Cauchy process that has infinitely many jumps on every finite interval. But may be one can find \( q_0 \) such that for \( q_0 < q < 1 \) the \( q \)-Wiener process has only finite number of jumps on every finite interval?

(2) What is the distribution of the size of jumps of \((\alpha, q)\)-OU process. It is stationary. But is it of continuous, discrete or singular type. Or may be it is a mixture?

(3) On the other hand for every \( \varepsilon > 0 \) there are only finite number of jumps of the size not less than \( \varepsilon \). It follows from the symmetry \((\alpha, q)\)-OU processes with respect to time argument that inter jumps intervals between such jumps have the same distributions. What is the distribution of the length of those intervals. Strong Markov property would suggest exponential distribution. Is it true? Do they form a renewal process i.e. are those intervals independent? Probably not, but it needs justification.

(4) What are the properties of quadratic variations of martingales associated with \( q \)-Wiener processes.

(5) Recently Anshelevich et al. (see [12]) have proved so called free infinite divisibility of \( q \)-Normal distribution. Is transitional distribution with density \( f_{CN} \) also free infinitely divisible?

6. Proofs of the results

Proof of Lemma 5. 1. Remembering that \( H_4 (x|q) = x^4 - (3 + 2q + q^2)x^2 + (1 + q + q^2) \) we have
\[ x^4 = H_4 (x|q) + (3 + 2q + q^2)H_2 (x|q) + 2 + q. \]
Hence \( \mathbb{E} X_n^4 = 2 + q \) since \( \mathbb{E} H_4 (X_m) = \mathbb{E} H_2 (X_m) = 0 \). Now using the fact that
\[ \mathbb{E} (H_2 (X_n)|\mathcal{F}_{\leq m}) = \rho^{2(n-m)}H_2 (X_m) \]
for \( m < n \) we get:
\[ \mathbb{E} \left( X_n^2 X_m^2 \right) = \mathbb{E} X_m^2 \left( H_2 (X_n|q) + 1 \right) = 1 + \mathbb{E} \left( X_m^2 \mathbb{E} (H_2 (X_n|q)|\mathcal{F}_{\leq m}) \right) = 1 + \rho^{2(n-m)} \mathbb{E} X_m^2 H_2 (X_m) = 1 + \rho^{2(n-m)} \mathbb{E} \left( X_m^4 - X_m^2 \right) = 1 + \rho^{2(n-m)} (2 + q - 1). \]
To get (5.13), we have:
\[
\mathbb{E}X_n^2 X_{n-j} X_{n+k} = \mathbb{E} \left( X_n^2 X_{n-j} \mathbb{E} (X_{n+k} | \mathcal{F}_{\leq n}) \right) = \rho^k \mathbb{E} \left( X_n^2 X_{n-j} \right) = \rho^{k+j} \mathbb{E} \left( X_n^2 \mathbb{E} (X_{n-j} | \mathcal{F}_{\geq n}) \right) = \rho^{k+j} \mathbb{E} X_n^4 = \rho^{k+j} (2 + q).
\]

Proof of Proposition 7. For fixed natural numbers \(k, j\) let us denote \(Z_i = \mathbb{E} (X_{n+i} | \mathcal{F}_{\leq n-k, \geq n+j})\). Let \(\mathbf{Z} = [Z_i]_{i=-k+1}^{j-1}\). Now notice that for each coordinate of the vector \(\mathbf{Z}\) we have:
\[
Z_i = \mathbb{E} (X_i | \mathcal{F}_{\leq n-k, \geq n+j}) = \mathbb{E} (\mathbb{E} (X_i | \mathcal{F}_{\neq i}) | \mathcal{F}_{\leq n-k, \geq n+j})
\]
\[
= \frac{\rho}{1 + \rho^2} (\mathbb{E} (X_{i-1} | \mathcal{F}_{\leq n-k, \geq n+j}) + \mathbb{E} (X_{i+1} | \mathcal{F}_{\leq n-k, \geq n+j}))
\]
\[
= \begin{cases} 
\frac{\rho}{1 + \rho^2} (Z_{i-1} + Z_{i+1}) & \text{if } i \neq -k + 1 \lor j - 1 \\
\frac{\rho}{1 + \rho^2} X_{n-k} + \frac{\rho}{1 + \rho^2} Z_{k+2} & \text{if } i = -k + 1 \\
\frac{\rho}{1 + \rho^2} X_{n+j} + \frac{\rho}{1 + \rho^2} Z_{j-2} & \text{if } i = j - 1
\end{cases}
\]

Hence we have a vector linear equation
\[
\mathbf{Z} = \mathbf{A} \mathbf{Z} + \mathbf{J},
\]
where
\[
\mathbf{A} = \begin{bmatrix} 
0 & \rho & 0 & \cdots & 0 \\
\frac{\rho}{1 + \rho^2} & 0 & \cdots & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
0 & 0 & \cdots & \frac{\rho}{1 + \rho^2} & 0
\end{bmatrix},
\]
\[
\mathbf{J} = \begin{bmatrix} 
\frac{\rho}{1 + \rho^2} X_{n-k} & 0 & \cdots & 0 & \frac{\rho}{1 + \rho^2} X_{n+j}
\end{bmatrix}.
\]

Now notice that the matrix \(\mathbf{I} - \mathbf{A}\) where \(\mathbf{I}\) denotes unity matrix is non-singular. This is so because sum of the absolute values of elements in each row of the matrix \(\mathbf{A}\) is less than 1 which means that eigenvalues of the matrix \(\mathbf{I} - \mathbf{A}\) are inside circle at center in 1 and radius less than 1, thus nonzero. Consequently each component of the vector \(\mathbf{Z}\) is a linear function of \(X_{n-k}\) and \(X_{n+j}\). Having linearity of \(\mathbb{E} (X_i | \mathcal{F}_{\leq n-k, \geq n+j})\) with respect to \(X_{n-k}\) and \(X_{n+j}\) we get (5.2).

Let us denote \(m_{i,j} = \mathbb{E} (X_{n+i} X_{n+j} | \mathcal{F}_{\leq n-i, \geq n+j})\), for \(i, j = -l, -l+1, \ldots, k-1, k\). Notice that using (5.2) we get \(m_{i,j} = m_{j,i}\) and that \(m_{-i,j} = X_{n-i} \mathbb{E} (X_{n+j} | \mathcal{F}_{\leq n-i, \geq n+k})\)
\[
= \frac{\rho^{i+j} (1 - \rho^{2i-2})}{1 - \rho^{2+i}} X_{n-i}^2 + \frac{\rho^{j-i} (1 - \rho^{2j-2})}{1 - \rho^{2+i}} X_{n-i} X_{n+k} + m_{k,j} = X_{n+k} \mathbb{E} (X_{n+j} | \mathcal{F}_{n-l, \geq n+k})
\]
\[
= \frac{\rho^{i+j} (1 - \rho^{2i-2})}{1 - \rho^{2+i}} X_{n-i} X_{n+k} + \frac{\rho^{k-j} (1 - \rho^{2k-2})}{1 - \rho^{2+i}} X_{n+k}^2,
\]

Besides we have for \(i, j = -l + 1, \ldots, k-1\) and \(i \neq j\)
\[
m_{i,j} = \mathbb{E} (X_{n+i} X_{n+j} | \mathcal{F}_{\leq n-i, \geq n+k}) = \mathbb{E} \left( X_{n+i} \mathbb{E} (X_{n+j} | \mathcal{F}_{\neq n+j}) | \mathcal{F}_{n-l, \geq n+k} \right)
\]
\[
= \frac{\rho}{1 + \rho^2} (m_{i,j-1} + m_{i,j+1})
\]
and if \(i = j\)
\[
m_{i,i} = \mathbb{E} \left( X_{n+i}^2 | \mathcal{F}_{\leq n-i, \geq n+k} \right) = \mathbb{E} \left( X_{n+i}^2 | \mathcal{F}_{\neq n+i} \right) | \mathcal{F}_{n-l, \geq n+k}
\]
\[
= A (m_{i-1,i-1} + m_{i+1,i+1}) + B m_{i-1,i+1} + C
\]

Notice also that we have in fact \((l + k - 2)^2\) unknowns and \((l + k - 2)^2\) linear equations. Moreover random variables \(m_{ij}\) are well defined since conditional expectation
is uniquely defined (up to set of probability 1). Thus we get the main assertion of the proposition. Now we know that for some \( A_j, B_j, C_j \) we have

\[
(6.1) \quad \mathbb{E}(X_n^2 | \mathcal{F}_{n-j, n+k}) = A_{jk}^{(1)} X_{n-j}^2 + A_{jk}^{(2)} X_{n+k}^2 + B_{jk} X_{n-j} X_{n+k} + C_{jk}.
\]

First thing to notice is that (consequence of calculating expectation of both sides of (6.1))

\[
1 = A_{jk}^{(1)} + A_{jk}^{(2)} + \rho^{j+k} B_{jk} + C_{jk}.
\]

Secondly let us multiply (6.1) by \( X_{n-j}^2, X_{n+k}^2 \) and \( X_{n-j} X_{n+k} \) and let us take expectation of both sides of obtained in that way equalities. In doing so we apply assertions of Lemma 2. In this way we will get three equations:

\[
1 + \rho^{2j}(1 + q) = A_{jk}^{(1)} (2 + q) + A_{jk}^{(2)} (1 + \rho^{2(j+k)} (1 + q)) + B_{jk} \rho^{j+k} (2 + q) + 1 - A_{jk}^{(1)} - A_{jk}^{(2)} - \rho^{j+k} B_{jk}
\]

\[
1 + \rho^{2k}(1 + q) = A_{jk}^{(1)} \left( 1 + \rho^{2(j+k)} (1 + q) \right) + A_{jk}^{(2)} (2 + q) + B_{jk} \rho^{j+k} (2 + q) + 1 - A_{jk}^{(1)} - A_{jk}^{(2)} - \rho^{j+k} B_{jk}
\]

\[
\rho^{j+k} (2 + q) = A_{jk}^{(1)} \rho^{j+k} (2 + q) + A_{jk}^{(2)} \rho^{j+k} (2 + q) + B_{jk} \left( 1 + \rho^{2(j+k)} (1 + q) \right) + \rho^{j+k} \left( 1 - A_{jk}^{(1)} - A_{jk}^{(2)} - \rho^{j+k} B_{jk} \right).
\]

Solution of this system of equations is \( Z_{k} \), as it can be easily checked.

Proof of Lemma 2. Consider discrete time random field \( Z = \{Z_k\}_{k \in \mathbb{Z}} \) such that \( Z_k = X_{kj+m} \), for some fixed \( j \) and \( 0 \leq m \leq j - 1 \). Obviously we have

\[
\mathbb{E}(Z_k | \mathcal{F}_{\neq k}) = \mathbb{E}(X_{kj+m} | \mathcal{F}_{\leq (k-1)j+m, \geq (k+1)j+m}) = \frac{\rho^j}{1 + \rho^{2j}} (Z_{k-1} + Z_{k+1}),
\]

and

\[
\mathbb{E}(Z_k^2 | \mathcal{F}_{\neq k}) = \mathbb{E}(X_{kj+m}^2 | \mathcal{F}_{\leq (k-1)j+m, \geq (k+1)j+m}) = A_j (X_{(k-1)j+m} + X_{(k+1)j+m}) + B_j X_{(k-1)j+m} X_{(k+1)j+m} + C_j = A_j (Z_{k-1}^2 + Z_{k+1}^2) + B_j Z_{k-1} Z_{k+1} + C_j,
\]

where \( A_j = A_{1j}^{(1)} = A_{1j}^{(2)} \), \( B_j = B_{1j} \). Thus \( Z \) is 1TSP with different parameters. Notice that one dimensional distributions of processes \( X \) and \( Z \) are the same. Hence parameters \( q \) for both processes \( Z \) and \( X \) are the same. On the other hand parameter \( \rho_Z \) of the process \( Z \) is related to parameter \( \rho \) of the process \( X \) by the following relationship

\[
\rho_Z = \mathbb{E}Z_0 Z_1 = \mathbb{E}X_0 X_j = \rho^j.
\]

Thus applying formulae (2.4) we get (5.3).

Proof of Theorem 7. From Lemma 2 of the previous section it follows that if for some \( \delta > 0 \) \( X = \{X_n^{(\delta)}\}_{n \in \mathbb{Z}} \) is a regular 1TSP with some parameters \( q \) and \( \rho \), then for every \( j \) and \( m \in \{0, \ldots, j-1\} \), process \( Z^{(m)}_k = X_{kj+m}^{(\delta)} \) is also the 1TSP with the same parameter \( q \) and parameter \( \rho_z = \rho^{j} \). Notice however that \( Z^{(0)}_k = X^{(\delta)}_k \).
Similarly if we considered process $\tilde{X} = \left\{ X^{(\delta/j)}_n \right\}_{n \in \mathbb{Z}}$, then since $X^{(\delta)}_n = \tilde{X}^{(\delta/j)}_{nj}$ and the fact that one 1TSP is characterized by one parameter $q$ we deduce that processes $X$ and $\tilde{X}$ share the same parameter $q$. Hence the fact that condition $(\delta)$ is satisfied for every $\delta$ implies that all implied by it regular 1TSP are characterized by one, same parameter $q$. Further since for same $\delta > 0$ regular 1TSP $\left\{ X^{(\delta)}_n \right\}_{n \in \mathbb{Z}}$ is $L_2$ stationary with covariance function $K(n,m) = \rho(\delta)^{n-m} = \mathbb{E}X^{(\delta)}_0 X^{(\delta)}_{|n-m|}$, we have also for any integer $k$: $\rho(\delta)^n = \mathbb{E}X^{(\delta)}_0 X^{(\delta)}_n = \mathbb{E}X^{(\delta/k)}_0 X^{(\delta/k)}_{nk} = \rho(\delta/k)^{nk}$. Or equivalently we have
\[
\forall k \in \mathbb{Z}; \delta, \theta > 0 : \rho(\delta) = \rho(\delta/k)^k, \rho(k\theta) = \rho(\theta)^k.
\]
Now take $\delta = \frac{k}{m}\theta$ for some $\theta$. We will get then $\rho(\frac{k}{m}\theta) = \rho(\theta)^{\frac{k}{m}}$. Now let us take sequences of integers $\{k_n, m_n\}$ such that $\frac{k_n}{m_n} \to 1/\theta$ then, using $L_2$-continuity we get
\[
\rho(\theta) = \rho(1)^\theta.
\]
In other words we deduce that if $Y$ existed, then it would be $L_2$-stationary with covariance function
\[
K(t,s) = K(|s-t|) = \rho(1)^{|s-t|}.
\]
for some $\rho(1) \in (0,1)$. Let us introduce new parameter
\[
\alpha = \log -\frac{1}{\rho(1)} > 0.
\]
We have then
\[
K(s,t) = \exp (-\alpha |s-t|).
\]
Consequently the fact that condition $(\delta)$ is satisfied for every $\delta$ implies that all implied by it regular 1TSP are characterized by one, same parameter $q$ and covariance function defined by same parameter $\alpha$.

Existence of $Y$ will be shown for two cases separately. Since for $q = 1$ we have normality of the one dimensional and conditional distributions. Thus we deduce that the process $Y$ for $q = 1$ is in fact the well known Ornstein–Uhlenbeck process. Now let us consider fixed $q \in (-1, 1)$. First we will deduce the existence of the process $\hat{Y} = (Y_t)_{t \in \mathbb{Q}}$. This follows from Kolmogorov’s extension theorem. Since having natural ordering of $\mathbb{Q}$ we need only consistency of the family of finite dimensional distributions of $\hat{Y}$. This can be however easily shown by the following argument. Let us take finite set of numbers $r_1 < r_2 < \cdots < r_n$ from $\mathbb{Q}$. Let $M$ denote the smallest common denominator of these numbers. Let us consider regular 1TSP $X^M$ with $q$ and $\hat{\alpha} = \alpha/M$. Note that then $X^M_n = Y_{n/M}$ for $n \in \mathbb{N}$. Then joint distribution of $(Y_{r_1}, \ldots, Y_{r_n})$ is in fact a joint distribution of $(X^M_{R_1}, \ldots, X^M_{R_n})$ where numbers $R_1, \ldots, R_n$ are defined by the relationships $r_i = R_i/M$. Since process $X^M$ exists we have consistency since if $\{r_1, \ldots, r_k\} \subset \{r_1, \ldots, r_n\}$ then distribution of $(Y_{r_1}, \ldots, Y_{r_k})$ being equal to the distribution of $(X^M_{R_1}, \ldots, X^M_{R_k})$ with $T_j$ defined by $\tau_j = T_j/M$ for $j = 1, \ldots, k$ is a projection of the distribution of $(Y_{r_1}, \ldots, Y_{r_n})$. Hence we deduce that the process $\hat{Y}$ with values in the compact space $S(q)$, exist. Now we use separability theorem (see e.g. [24]) and view $\hat{Y}$ as separable modification of the process $Y$ itself. Hence the process $Y$ exists. □
Proof of Theorem 3: i) The fact that \( EY_t^2 = 1 \) and that for \( s \geq 0 \), \( \text{var}(Y_{t+s}|Y_t) = 1 - e^{-2\alpha s} \) follows from (1.3) and (1.4) and the definition of polynomials \( p_n \) for \( n = 1, 2 \). If \( q = 1 \) then we have OU process and the assertion is true. For \( |q| < 1 \), we apply assertion of the Theorem 3 page 180 of [24] and the following estimation based on Chebyshev inequality.

\[
\gamma_{\varepsilon}(t) = \sup_{y \in S(q), t \leq h} P\left(|Y_{t+s} - Y_s| \geq \varepsilon | Y_s = y\right) \leq \frac{E|Y_{t+s} - Y_s|^2}{\varepsilon^2} \leq 2 \text{var}\left(|Y_{t+s}|\right) + 2E\left(|Y_s - e^{-\alpha t}Y_s|^2 | Y_s = y\right)
\]

\[
= \frac{2(1 - e^{-2\alpha t}) + 2q^2(1 - e^{-\alpha t})^2}{\varepsilon^2} \approx \frac{4\alpha t + 8\alpha^2 t^2/(1 - q)}{\varepsilon^2}
\]

from which it follows that \( \forall \varepsilon > 0, \gamma_{\varepsilon}(t) > 0 \) as \( t \to 0 \). Another justification of this assertion follows properties of martingales and is given below.

ii) Following observations: 1. \( q \)-Hermite polynomials are the orthogonal basis of the space denoted by \( B(q) \). 2. Conditional distributions of \( Y_{t+s}|Y_t = y \) having densities \( f_{CN}(x|y, e^{-\alpha s}, q) \) form a continuous semigroup following Lemma 1 iv). 3. (4.10) follows Lemma 1 ii).

iii) If \( q = 1 \) then we deal with classical OU process that has both Feller property and is strongly Markov. For \( |q| < 1 \) we use the fact that \( |H_i(x|q)| \leq W_i(q)/(1 - q)^{i/2} \) by Lemma 1 v), (4.10) together with Lemma 1 vi) guarantees that

\[
\max_{x \in S(q)} |P^r(f)(x)| \leq \frac{\max_{j \geq 0} |b_j \sqrt{\gamma}_j|}{(exp(-\alpha t))^2},
\]

where coefficients \( b_i \) are defined by

\[
B(q) \ni f(x) = \sum_{j \geq 0} \frac{b_j}{\sqrt{j}!}H_j(x|q).\]

Thus if \( f \) was continuous and bounded, then \( P^r(f)(x) \) is also continuous and bounded. Hence we have Feller property. To get strong Markov property we use Theorem 1 of section 9.2 of [24] that asserts that every time homogeneous Markov family, having càdlàg trajectories and Feller property is also strongly Markov.

iv) Let us consider function \( f \in B(q) \) and take \( n_0 \in \mathbb{N} \) such that

\[
\max\left( \sup_{x \in S(q)} \left| \sum_{n \geq n_0} \frac{b_n}{\sqrt{n}!}H_n(x|q) \right|, \sup_{x \in S(q)} \left| \sum_{n \geq n_0} e^{-n \alpha t} \frac{b_n}{\sqrt{n}!}H_n(x|q) \right| \right) \leq \varepsilon
\]

for some chosen beforehand \( \varepsilon > 0 \). Since on the compact space \( S(q) \) uniform convergence to a continuous function is equivalent to pointwise convergence and since from \( L_2 \) convergence follows existence of a subsequence \( \{k_n\} \) such that \( \sum_{j \geq 0} \frac{b_j}{\sqrt{j}!}H_j(x|q) \) converges pointwise to its continuous limit, we deduce that such \( n_0 \) exists. Now we notice

\[
\sup_{x \in S(q)} |f(x) - P^r(f)(x)| \leq 2\varepsilon + \sup_{x \in S(q)} \left| \sum_{j=0}^{n_0-1} (1 - e^{-j\alpha t}) \frac{b_j}{\sqrt{j}!}H_j(x|q) \right| \leq 3\varepsilon,
\]
if only $\tau$ is sufficiently small. Hence
\[
\lim_{\tau \to 0^+} \sup_{x \in \mathbb{S}(q)} |f(x) - P^\tau(f)(x)| = 0,
\]
and consequently we see that $\{P^\tau(f)\}_{\tau \geq 0}$ is a right continuous meaning that process $Y$ is a Feller process. Thus the infinitesimal operator $A$ exists. Its value on $H_n(x|q)$ can be found by the following argument:
\[
AH_n(x|q) = \lim_{h \downarrow 0^+} \frac{1}{h} (E(H_n(Y_{t+h}|q) | Y_t = x) - H_n(x|q))
\]
\[
= \lim_{h \downarrow 0^+} \frac{1}{h} \left( e^{-\alpha h}H_n(x|q) - H_n(x|q) \right) = -\alpha H_n(x|q).
\]

\textbf{Proof of Theorem 3.} 1. Suppose $\tau < \sigma$,
\[
\text{cov}(X_\tau, X_\sigma) = \sqrt{\sigma \sigma} \text{E} Y_{\log \tau/2\alpha} Y_{\log \sigma/2\alpha} = \sqrt{\tau \tau} e^{-\alpha|\log \tau/2\alpha - \log \sigma/2\alpha|}
\]
\[
= \sqrt{\tau \sigma} e^{-\log(\sigma/\tau)/2} = \sqrt{\tau \sigma} \sqrt{\sigma/\tau} = \sigma.
\]

2. & 3. We have $\mathbb{P}(X_\tau \leq y) = \mathbb{P}(\sqrt{\tau} Y_{\log \tau/2\alpha} \leq y) = \mathbb{P}(Y_{\log \tau/2\alpha} \leq \frac{y}{\sqrt{\tau}})$. Knowing that $f_N$ is a density of $Y_t$ given $Y_s = s$, by theorem[2] we have
\[
\mathbb{P}(X_\tau - X_\sigma \leq x|X_\sigma = y) = \mathbb{P}(X_\tau \leq x+y|X_\sigma = y) = \mathbb{P}(\sqrt{\tau} Y_{\log \tau/2\alpha} \leq x+y|Y_{\log \sigma/2\alpha} = \frac{y}{\sqrt{\tau}}).
\]

Now we recall that $f_{CN}(x|y,q,e^{-\alpha|x-t|})$ is the density of $Y_t$ given $Y_s = s$, by theorem[2]
\[
4. \text{Notice that } X_\tau/\sqrt{\tau} = Y_{\log \tau/2\alpha}. \text{ We have using assertion 5 of Theorem [2]}
\]
\[
\mathbb{E} \left( \tau^{n/2} H_n \left( \frac{X_\tau}{\sqrt{\tau}} \right) \mathcal{F}_\leq \sigma \right) = \tau^{n/2} \mathbb{E} \left( H_n \left( Y_{\log \tau/2\alpha} \right) \mathcal{F}_{\log \sigma/2\alpha} \right) = \tau^{n/2} e^{-\alpha (\log \tau/2\alpha - \log \sigma/2\alpha)} H_n \left( Y_{\log \sigma/2\alpha} \right) = \sigma^{n/2} H_n \left( X_\sigma/\sqrt{\sigma} \right).
\]
a.s.

Similarly
\[
\mathbb{E} \left( \sigma^{-n/2} H_n \left( \frac{X_\sigma}{\sqrt{\sigma}} \right) \mathcal{F}_{\geq \tau} \right) = \sigma^{-n/2} \mathbb{E} \left( H_n \left( Y_{\log \sigma/2\alpha} \right) \mathcal{F}_{\log \tau/2\alpha} \right) = \sigma^{-n/2} e^{-\alpha (\log \tau/2\alpha - \log \sigma/2\alpha)} H_n \left( Y_{\log \tau/2\alpha} \right) = \tau^{-n/2} H_n \left( \frac{X_\tau}{\sqrt{\tau}} \right).
\]

5. to get first part we proceed as follows:
\[
\sqrt{\tau} \mathbb{E} \left( Y_{\log \tau/2\alpha} \mathcal{F}_{\leq \log (\sigma-\delta)/2\alpha, \geq \log (\sigma+\gamma)/2\alpha} \right) = \sqrt{\sigma} \left( \frac{1 - \sigma/(\sigma+\gamma)}{1 - (\sigma-\delta)/(\sigma+\gamma)} \right) Y_{\log (\sigma-\delta)/2\alpha}
\]
\[
+ \frac{\frac{\sigma}{(\sigma+\gamma)} (1 - (\sigma-\delta)/\sigma) \gamma}{\frac{\sigma-\delta}{\sigma+\gamma}} Y_{\log (\sigma+\gamma)/2\alpha} = \frac{\gamma}{\delta+\gamma} X_{\sigma-\delta} + \frac{\delta}{\delta+\gamma} X_{\sigma+\gamma}.
\]
To get second part we have:

$$
\text{E} \left( X^2_\sigma \mid F^X_{\leq \sigma - \delta \geq \sigma + \gamma} \right) = \sigma \text{E} \left( Y^2_{\log \sigma / 2\alpha} \mid F^Y_{\leq \log(\sigma - \delta) / 2\alpha, \geq \log(\sigma + \gamma) / 2\alpha} \right) \\
= \frac{\sigma - \delta}{\sigma} \frac{1 - \frac{\sigma}{\sigma + \gamma}}{1 - \frac{\sigma - \delta}{\sigma + \gamma}} Y^2_{\log(\sigma - \delta) / 2\alpha} + \sigma \frac{1 - \frac{\sigma}{\sigma + \gamma}}{1 - \frac{\sigma - \delta}{\sigma + \gamma}} Y^2_{\log(\sigma + \gamma) / 2\alpha}
$$

$$(q + 1) \sqrt{\frac{\sigma - \delta}{\sigma + \gamma}} \frac{1 - \frac{\sigma}{\sigma + \gamma}}{1 - \frac{\sigma - \delta}{\sigma + \gamma}} Y^2_{\log(\sigma - \delta) / 2\alpha} Y_{\log(\sigma + \gamma) / 2\alpha} + \sigma \frac{1 - \frac{\sigma}{\sigma + \gamma}}{1 - \frac{\sigma - \delta}{\sigma + \gamma}}.
$$

Keeping in mind that $X_\tau = \sqrt{\frac{\tau}{2}} Y_{\log \tau / 2\alpha}$ we get:

$$
\text{E} \left( X^2_\sigma \mid F^X_{\leq \sigma - \delta \geq \sigma + \gamma} \right) = \frac{\gamma (1 - q) \sigma + \gamma}{(\delta + \gamma) (\sigma (1 - q) + \gamma + \gamma \delta)} X^2_\sigma - \delta + \frac{\delta ((1 - q) \sigma + \gamma \delta)}{(\delta + \gamma) (\sigma (1 - q) + \gamma + \gamma \delta)} X^2_\sigma + \gamma + (q + 1) \delta \gamma \frac{1 - \frac{\sigma}{\sigma + \gamma}}{1 - \frac{\sigma - \delta}{\sigma + \gamma}}.
$$

\(\square\)

**Proof of Corollary**

To prove i) we calculate:

$$
\text{E} \left( (X_\tau - X_\sigma)^2 \mid F^X_{\leq \sigma} \right) = \text{E} \left( X^2_\tau \mid F^X_{\leq \sigma} \right) - 2X^2_\sigma + X^2_\sigma = X^2_\sigma + \tau - \sigma - X^2_\sigma = \tau - \sigma.
$$

$$
\text{E} \left( (X_\tau - X_\sigma)^3 \mid F^X_{\leq \sigma} \right) = \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) - 3X_\sigma \text{E} \left( X^2_\tau \mid F^X_{\leq \sigma} \right) + 3X^2_\sigma \text{E} \left( X_\tau \mid F^X_{\leq \sigma} \right) - X^3_\sigma
$$

$$
= \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) - 3X_\sigma \text{E} \left( X^2_\tau \mid F^X_{\leq \sigma} \right) + 2X^3_\sigma.
$$

$$
\text{E} \left( (X_\tau - X_\sigma)^4 \mid F^X_{\leq \sigma} \right) = \text{E} \left( X^4_\tau \mid F^X_{\leq \sigma} \right) - 4X_\sigma \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) + 6X^2_\sigma \text{E} \left( X^2_\tau \mid F^X_{\leq \sigma} \right) - 4X^3_\sigma \text{E} \left( X_\tau \mid F^X_{\leq \sigma} \right) + X^4_\sigma
$$

$$
= \text{E} \left( X^4_\tau \mid F^X_{\leq \sigma} \right) - 4X_\sigma \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) + 3X^4_\sigma + 6(\tau - \sigma) X^2_\sigma.
$$

Now recalling that $H_2 (x | q) = x^2 - 1$, $H_3 (x | q) = x^3 - (2 + q) x$ and $H_4 (x | q) = x^4 - (3 + 2q + q^2)x^2 + (1 + q + q^2)$ we see that:

$$
\sigma H_2 \left( \frac{X_\sigma}{\sqrt{\sigma}} q \right) = \text{E} \left( \tau H_2 \left( \frac{X_\tau}{\sqrt{\tau}} q \right) \mid F^X_{\leq \sigma} \right),
$$

$$
\sigma^{3/2} H_3 \left( \frac{X_\sigma}{\sqrt{\sigma}} q \right) = \text{E} \left( \tau^{3/2} H_3 \left( \frac{X_\tau}{\sqrt{\tau}} q \right) \mid F^X_{\leq \sigma} \right)
$$

$$
= \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) - \tau (2 + q) \text{E} \left( X_\tau \mid F^X_{\leq \sigma} \right)
$$

and

$$
\sigma^2 H_4 \left( \frac{X_\sigma}{\sqrt{\sigma}} q \right) = \text{E} \left( \tau^2 H_4 \left( \frac{X_\tau}{\sqrt{\tau}} q \right) \mid F^X_{\leq \sigma} \right)
$$

$$
= \text{E} \left( X^4_\tau \mid F^X_{\leq \sigma} \right) - \tau (3 + 2q + q^2) \times \text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) + (1 + q + q^2)^{r^2}.
$$

Thus

$$
\text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) = X^3_\sigma + \tau - \sigma.
$$

$$
\text{E} \left( X^3_\tau \mid F^X_{\leq \sigma} \right) = \tau (2 + q) X_\sigma + X^3_\sigma - \sigma (2 + q) X_\sigma = (\tau - \sigma) (2 + q) X_\sigma + X^3_\sigma
$$
To get (4.16) we perform the following calculations.

\[ \mathbb{E}(X_2^4 | \mathcal{F}_X^{\infty} \varnothing) = X_\sigma^4 + (\tau - \sigma)(3 + 2q + q^2)X_\sigma^2 + (\tau - \sigma)(\tau + \sigma)(1 + q + q^2). \]

So

\[ \mathbb{E}\left( (X_T - X_\sigma)^3 | \mathcal{F}_X^{\infty} \varnothing \right) = (\tau - \sigma)(2 + q)X_\sigma + X_\sigma^3 - 3X_\sigma (X_\sigma^2 + \tau - \sigma) + 2X_\sigma^3 \]

\[ = -(1 - q)(\tau - \sigma)X_\sigma, \]

\[ \mathbb{E}\left( (X_T - X_\sigma)^4 | \mathcal{F}_X^{\infty} \varnothing \right) = 3X_\sigma^4 + 6(\tau - \sigma)X_\sigma^2 + X_\sigma^4 + (\tau - \sigma)(3 + 2q + q^2)X_\sigma^2 + (\tau - \sigma)(3 + 2q + q^2)X_\sigma^2 + (\tau - \sigma)(2 + q)X_\sigma^2 \]

\[ = X_\sigma^2(\tau - \sigma)(1 - q)^2 + (2 + q)(\tau - \sigma)^2 + (\tau - \sigma)(1 - q^2). \]

If \( X \) had independent increments then \( \mathbb{E}\left( (X_T - X_\sigma)^4 | \mathcal{F}_X^{\infty} \varnothing \right) \) would not depend on \( X_\sigma^2 \). Note that for \( q = 1 \) we have \( \mathbb{E}\left( (X_T - X_\sigma)^4 | \mathcal{F}_X^{\infty} \varnothing \right) \) = 3(\( \tau - \sigma \)^2 = 3\( \mathbb{E}\left( (X_T - X_\sigma)^2 | \mathcal{F}_X^{\infty} \varnothing \right) \).

ii) Follows properties of martingales. Thus almost every path of the process \( X \) has no oscillatory discontinuities, in other words has at every point \( t \) left and right hand side limit. Since process \( Y \) is obtained from the process \( X \) by continuous transformation it has similar properties.

iii) Follows the fact that \( q \)-Wiener process is obtained from \((\alpha, q)\)-OU process by continuous (even smooth) transformation \( \{4.19\} \). On its side \((\alpha, q)\)-OU has Feller property and is strongly Markov as shown in Theorem \{3\}iii). □

**Proof of Corollary** \[ \] Following given formulae we have for \( n = 1 \) and \( n = 2 \) : \( A_0^{(1)} = \frac{\gamma}{\tau - \delta} \sqrt{\frac{\sigma - \delta}{\sigma}} \), \( A_0^{(2)} = \frac{\sigma - \delta}{\sigma} \), \( A_0^{(2)} = \frac{\sigma - \delta}{\sigma} \), \( A_0^{(2)} = - \frac{\sigma - \delta}{\sigma} \)

\[ \left[ 2 \right] q \frac{(\sigma - \delta)(\sigma + \gamma)}{\sigma(\gamma + \delta)(\gamma + q + (1 - q)\sigma)} \]

we get immediately \( \{4.15a\}, \{4.15b\} \) and \( \{4.15c\} \).

To get \( \{4.16\} \) we perform the following calculations. \( \text{var}\left( X_\sigma | \mathcal{F}_X^{\infty} \varnothing \right) = \mathbb{E}\left( X_\sigma^2 | \mathcal{F}_X^{\infty} \varnothing \right) - \left( \mathbb{E}\left( X_\sigma | \mathcal{F}_X^{\infty} \varnothing \right) \right)^2 \). Hence

\[ \text{var}\left( X_\sigma | \mathcal{F}_X^{\infty} \varnothing \right) = \frac{\delta \gamma}{\sigma(1 - q) + \gamma + q \delta} + X_{\sigma - \delta} \left( \frac{\gamma(\delta + \gamma)}{(\delta + \gamma)(\sigma(1 - q) + \gamma + q \delta)} \right) \]

\[ + X_{\sigma + \gamma} \left( \frac{\delta(1 - q) + \gamma}{\sigma(1 - q) + \gamma + q \delta} \right) \]

\[ + \frac{\gamma^2}{\sigma(1 - q) + \gamma + q \delta} - \frac{(4 \delta)^2}{\delta + \gamma) \].
Proof of Remark 14. After some simplifications we get
\[
\var(X_\sigma|F^{X}_{\leq \sigma-\delta, \geq \sigma + \gamma}) = \frac{\delta \gamma}{(\sigma - 1) + \gamma + q \delta} + \frac{(1 - q) \delta \gamma (\delta + \gamma)}{(\sigma - 1) + \gamma + q \delta} X^{\sigma - \delta}_{\sigma + \gamma}
\]
\[
+ \frac{(1 - q) \delta \gamma (\sigma - \delta)}{(\sigma - 1) + \gamma + q \delta} \frac{(1 - q) \gamma \delta \sigma (2 \sigma - \delta + \gamma)}{\gamma + \delta} X^{\sigma + \gamma}_{\sigma - \delta} X^{\sigma + \gamma}_{\sigma - \delta}
\]
\[
= \frac{(1 - q) \gamma \delta (\sigma - 1 + \gamma + q \delta)}{\gamma + \delta^2} (\gamma - \sigma - \delta) X^{\sigma + \gamma}_{\sigma - \delta} X^{\sigma + \gamma}_{\sigma - \delta}.
\]
□

Proof of Corollary 3. We multiply both sides of both formulae given in assertion 4 of Theorem 3 by \(s^n/n_q\) and sum over \(n\) from 0 to \(\infty\). Now one has to use that fact that such a sum is absolutely convergent in the case of (4.10) for \(s^2 \sigma (1 - q) < 1\), while in the case of (4.11) for \(s^2 (1 - q)/\sigma < 1\). Changing order of summation and conditional expectation and applying formula 1.4 of [3] giving generating function of \(q\)-Hermite polynomials, leads to (4.17) and (4.18) respectively. For \(q = 1\) we use the same formulae but this time multiplied by \(s^n/n!\) and after summing up with respect to \(n\) we apply well known formula for generating functions of Hermite polynomials.
