Abstract The Lasserre’s reconstruction algorithm is extended to the D-polytopes with the construction of their shape space. Thus, the areas of d-skeletons (1 ≤ d ≤ D) can be expressed as functions of the areas and normal bi-vectors of the (D-1)-faces of D-polytopes. As weak solutions of the simplicity constraints in all dimensional loop quantum gravity, the simple coherent intertwiners are employed to describe semiclassical D-polytopes. New general geometric operators based on D-polytopes are proposed by using the Lasserre’s reconstruction algorithm and the coherent intertwiners. Such kind of geometric operators have expected semiclassical property by the definition. The consistent semiclassical limit with respect to the semiclassical D-polytopes can be obtained for the usual D-volume operator in all dimensional loop quantum gravity by fixing its undetermined regularization factor case by case.

1 Introduction

The kinematic structure of (1+3)-dimensional loop quantum gravity (LQG) [1–4] indicates a picture of quantum Riemann geometry, wherein the Hilbert space of this theory is given by the completion of the space of cylindrical functions on certain quantum configuration space. A cylindrical function $f_\gamma$ is based on a given graph $\gamma$ embedded in the 3-dimensional spatial hypersurface. The basic conceptions of the quantum Riemann geometry come from the 2-areas and 3-volumes of the dual polyhedra of the graph $\gamma$, which can be given by the spin representations labelling the edges and the intertwiners labelling the vertices of $\gamma$. In fact, for an $F$-valent vertex which is dual to a polyhedron with $F$ 2-faces, one could obtain a gauge-invariant intertwiner space $\mathcal{H}_F$ by quantizing certain classical phase space $\mathcal{S}_F$ [5–7], as introduced by Kapovich and Millson in [8]. The states of coherent intertwiners in $\mathcal{H}_F$ are labelled with the points in $\mathcal{S}_F$ and comprise an overcomplete basis in the kinematical Hilbert space of LQG based on the $F$-valent vertex. Moreover, the coherent intertwiner states can give the semiclassical 3-spatial geometry of polyhedra in large spin limit [7,9,10]. The idea that the coherent intertwiners can be regarded as the semiclassical states of certain spatial geometry in large quantum number limit was also extended to all dimensional LQG [11,12]. It provides a way to deal with the anomalous quantum simplicity constraints in all dimensional LQG with certain geometrical meaning. In this way, the non-commutative quantum vertex simplicity constraints [13] were imposed weakly [14], so that some kinds of weak solutions were constructed as well-behaved semiclassical states. These weak solutions are composed of $SO(D+1)$ coherent states [15] and comprise the so-called simple coherent intertwiner space in all dimensional LQG.

A natural question is whether the simple coherent intertwiner space can also be obtained by quantizing the shape space of D-polytopes directly, just as the special case in (1+3)-dimensional theory. The answer is negative. In fact, the construction of Kapovich and Millson’s phase space can be extended to higher dimensional cases but with some different characters as introduced in [14]. In this description, one considers the D-polytopes embedded into a (D+1)-dimensional Euclidean space $\mathbb{R}^{(D+1)}$. Thus, each of the (D-1)-faces of a D-polytope has a pair of normalized normal vectors in $\mathbb{R}^{(D+1)}$, such that one of them is the normal vector of the D-polytope, as shown in Fig. 1.

The pair of normal vectors compose a normalized bi-vectors which can be used to describe the orientation of the (D-1)-face. Then, one can construct the shape space based on the closure condition and an extra simplicity constraint, which ensures that these bi-vectors describe the normals of the (D-1)-faces of a D-polytope in $\mathbb{R}^{(D+1)}$ exactly. Also, the simplicity constraint leads to the fact that the shape space...
of D-polytopes is no longer a phase space. This may be taken as a new perspective to understand the anomaly of quantum vertex simplicity constraints. Hence the relation between the simple coherent intertwiners and D-polytopes in all dimensional LQG becomes worth studying. This is the main issue which will be studied in this paper. We will show that each gauge-invariant simple coherent intertwiner can be labelled by the geometric information of a D-polytope [16, 17], similar to the (1+3)-dimensional case. In particular, thanks to the Minkowski Theorems [18, 19] and the properties of $SO(D+1)$ coherent states [15], we can show that each gauge-invariant simple coherent intertwiner is a quantum state describing a semiclassical polytope $\mathcal{P}$, and the product of the out-oriented normal bi-vector $V_{i}^{IJ}$ and the area $A_i$ of $i_{th}$ (D-1)-face of $\mathcal{P}$ can be promoted as an operator $X_{i}^{IJ}$ in the intertwiner space.

With the realization of the above quantum correspondence, how to represent the quantum geometric information of a simple coherent intertwiner describing a semiclassical polytope is the next valuable issue. In classical theory, the Minkowski Theorems ensure that all of the geometric information of a D-polytope is contained in the normal bi-vectors $V_{i}^{I}$. The Minkowski Theorems [18, 19] and the proper-mation of a D-polytope is contained in the normal bi-vectors $M$. The bi-vectors $V_{i}^{I} = \sqrt{2n^{I}}V_{i}^{I}$ and $V_{k}^{J} = \sqrt{2n^{J}}V_{k}^{J}$ are the unit outward normal bi-vectors of the (D-1)-dimensional faces of $\mathcal{P}$ in $\mathbb{R}^{D+1}$.

2 The shape space of polytopes

2.1 Convex polytopes and Minkowski theorems

A D-dimensional convex polytope is a convex hull of a finite set of points in D-dimensional Euclidean space $\mathbb{R}^{D}$. It can be represented as the intersection of finitely many half-spaces
Theorem (H. Minkowski existence theorem). Let $\mathcal{P} = \{ x \in \mathbb{R}^D | V_i \cdot x \leq h_i, \hat{i} = 1, \ldots, m \}$,
(1)
where $V_i$ are arbitrary vectors, and $h_i$ are real numbers. The above abstract description is non-unique and redundant, as the minimal set of half-spaces needed to describe a D-polytope corresponds to taking their number $m$ equal to the number of (D-1)-faces $F$ of the D-polytope. In this paper we are interested in the description of a convex D-polytope with $F$ faces in terms of variables that have an immediate geometric interpretation: the areas of the (D-1)-faces of the D-polytope and the unit normals to the (D-1)-hyperplanes that support these (D-1)-faces. Let us consider a set of unit vectors $V_i \in \mathbb{R}^D$ and a set of positive real numbers $A_i$ such that they satisfy the closure condition
\[ C \equiv \sum_{i=1}^{F} A_i V_i = 0. \] (2)
A convex polytope with $F$ (D-1)-faces having areas $A_i$ and normals $V_i$ can be obtained in the following way. For each vector $V_i$, one considers the (D-1)-hyperplane in $\mathbb{R}^D$ orthogonal to it and translate it to a distance $h_i$ from the origin of $\mathbb{R}^D$. The intersection of the half-spaces bounded by these (D-1)-hyperplanes define the D-polytope, $V_i \cdot x \leq h_i$. Then, one can adjust the heights $h_i$ so that the (D-1)-hyperfaces have the expected areas $A_i$. Remarkably, a convex D-polytope with such (D-1)-faces’ areas and normals always exists. Moreover, it is unique, up to translations. This result is established by the following theorems due to Minkowski [18, 19]:

(i) Theorem (H. Minkowski uniqueness theorem). Let $D \geq 2$ and let two convex D-polytopes in $\mathbb{R}^D$ be such that, for every (D-1)-dimensional face of each of the D-polytope, the parallel face of the other D-polytope exists and has the same (D-1)-dimensional volume. Then the two D-polytopes are congruent and parallel to each other.

(ii) Theorem (H. Minkowski existence theorem). Let $D \geq 2$ and let $V_1, \ldots, V_m$ be unit vectors in $\mathbb{R}^D$ that do not lie in a closed half-space bounded by a (D-1)-hyperplane passing through the origin. Let $A_1, \ldots, A_m$ be positive real numbers such that $\sum_{i=1}^{m} A_i V_i = 0$. Denote by $A$ and $V$ the sets $\{A_1, \ldots, A_m\}$ and $\{V_1, \ldots, V_m\}$ respectively. Then there exists a convex D-polytope $\mathcal{P}(A, V)$ in $\mathbb{R}^D$ such that its (D-1)-faces’ number is $F = m$, the vectors $V_1, \ldots, V_m$ (and only they) are the unit outward normal vectors to the (D-1)-dimensional faces of $\mathcal{P}(A, V)$, and the (D-1)-dimensional areas of the corresponding (D-1)-faces are equal to $A_1, \ldots, A_m$ respectively.

The above discussions can be regarded as a direct generalization of the similar result for polyhedra in 3-dimensional Euclidean space, but the following discussions for general D-polytopes are different from 3-polyhedra.

2.2 Shape space of D-polytopes

The unit normal vector of a (D-1)-face in $\mathbb{R}^D$ is unique up to sign, and the configuration space of unit vectors in $\mathbb{R}^D$ is a (D-1)-dimensional unit sphere. In general, symplectic structure does not exist for an arbitrarily dimensional sphere. Hence we can not construct the phase space of general D-polytopes based on the (D-1)-sphere. In order to give a general formulation, let us consider the D-polytopes in (D+1)-dimensional Euclidean space $\mathbb{R}^{(D+1)}$. Given an unit vector $n_1 \in \mathbb{R}^{(D+1)}$, a subspace $\mathbb{R}_n^D \subset \mathbb{R}^{(D+1)}$ which satisfies $x_1 n_1 = 0, \forall x_1 \in \mathbb{R}^D$ can be fixed, wherein the index $I$ represents the abstract index to label the vector in $\mathbb{R}^{(D+1)}$. Following the result of last subsection, for two sets $A$ and $V^I$ satisfying $V^I_1 n_1 = 0, \forall i_1 = 1, \ldots, m$ and $\sum_{i=1}^{m} A_i V^I_i = 0$, we have an unique D-polytope $\mathcal{P}(A, V^I)$ in $\mathbb{R}^D$ up to translation. Notice that a (D-1)-face in $\mathbb{R}^{D+1}$ has an unique (up to sign) unit normal bi-vector $V^{IJ}_I$ and it takes the formulation $V^{IJ}_I = \sqrt{2} n^{IJ}_I V^J_I$ for the $i_{th}$ (D-1)-face of $\mathcal{P}(A, V^I)$ (see Fig.1). Thus we can reformulate H. Minkowski theorem of D-polytopes in $\mathbb{R}^{(D+1)}$ as:

Theorem (H. Minkowski theorem). Let $D \geq 2$ and $n_1, V^1_I, \ldots, V^m_I$ be unit vectors in $\mathbb{R}^{(D+1)}$ satisfying $n_1 V^I_i = 0, \forall i$, and $V^1_I, \ldots, V^m_I$ span a D-dimensional vector space. Let $A_1, \ldots, A_m$ be positive real numbers such that $\sum_{i=1}^{m} A_i V^I_i = 0$ or equivalently $\sum_{i=1}^{m} A_i V^{IJ}_i = \sqrt{2} \sum_{i=1}^{m} A_i n^{IJ} V^J_I = 0$. Denote by $A$ and $V^I$ the sets $\{A_1, \ldots, A_m\}$ and $\{V^1_I, \ldots, V^m_I\}$ respectively. Then there exists an unique (up to translation) convex D-polytope $\mathcal{P}(A, V^{IJ})$ in $\mathbb{R}^{(D+1)}$ with $F = m$ (D-1)-faces such that the bi-vectors $V^{IJ}_1, \ldots, V^{IJ}_m$ (and only they) are the unit outward normal bi-vectors of the (D-1)-dimensional faces of $\mathcal{P}(A, V^{IJ})$ and the (D-1)-dimensional areas of the corresponding (D-1)-faces are equal to $A_1, \ldots, A_m$ respectively.

In this formulation the area and unit normal bi-vectors are used to label (D-1)-faces of D-polytopes in $\mathbb{R}^{(D+1)}$. Let us consider the space of general bi-vectors $A V^{IJ}$ in $\mathbb{R}^{(D+1)}$ with norm $A$, which is given by $(Q_{D-1}, \Omega_{A^{D/2}})$, where $Q_{D-1} := SO(D+1)/(SO(2) \times SO(D-1))$ is a compact Kahler manifold and $\Omega_{A^{D/2}} := A \Omega$ with $\Omega$ being the corresponding Kahler form on $Q_{D-1}$ [22]. The complex quadric $Q_{D-1}$, as the set of all oriented 2-planes in $\mathbb{R}^{D+1}$, is a complex hypersurface defined by $(z_1)^2 + (z_2)^2 + \cdots + (z_{D+1})^2 = 0$ in the D-dimensional complex projective space $\mathbb{C}^P^D$ with homogeneous coordinates $z_1, z_2, \ldots, z_{D+1}$. There is the standard
The space \((Q_{D-1}, \Omega_{A_i^{2/2}})\) can be regarded as the phase space of the \((D-1)\)-faces with fixed \((D-1)\)-areas \((A_1, A_2, \ldots, A_F)\) of \(F\) \((D-1)\)-faces as \([14][23]\)

\[
\mathcal{Q}^V_{A_i} := \left\{ (A_1 V_1^{IJ}, \ldots, A_F V_F^{IJ}) \in Q_{D-1}(A_1) \times Q_{D-1}(A_2) \times \cdots \times Q_{D-1}(A_F) \left| \sum_{i=1}^{F} A_i V_i^{IJ} = 0, V_i^{[IJ} V_j^{KL]} = 0 \right. \right\} / SO(D+1),
\]

(5)

where \(Q_{D-1}(A_i) := (Q_{D-1}, \Omega_{A_i^{2/2}})\) is the phase space of \(A_i V_i^{IJ}\), \(V_i^{IJ}\) is the unit normal bi-vector of \(i\)th \((D-1)\)-face, and

\[
\sum_{i=1}^{F} A_i V_i^{IJ} = 0
\]

(6)

is the closure condition,

\[
V_i^{[IJ} V_j^{KL]} = 0
\]

(7)

is the so-called simplicity constraint \([11,24-26]\). The \(SO(D+1)\) rotation generated by the Hamiltonian vector field of closure condition preserves the constraint surfaces of closure condition and simplicity constraint. Thus, solving the closure condition and modulating the \(SO(D+1)\) rotations give a standard symplectic reduction process. As shown in \([27]\), by using the identity

\[
0 = V_i^{[IJ} V_j^{KL]} = V_i^{[IJ} V_j^{KL]} + V_j^{[IJ} V_i^{KL]}
\]

(8)

and the relation

\[
V_i^{[IJ} V_j^{KL]} = 0 \Leftrightarrow V_i^{[IJ} V_j^{KL]} = 0,
\]

(9)
\[ V_i \cdot x = h_i, \]
\[ V_j \cdot x \leq h_j, \quad \forall j \neq i. \quad (12) \]

We consider the generic case of \( V_i \cdot V_j \neq \pm 1, \forall \hat{i}, \hat{j} \) (the special configurations can be obtained as limit cases). It is convenient to introduce the coordinates \( y_i \) adapted to the (D-1)-face such that
\[ V_j \cdot y_i = 0, \quad y_i = x - (x \cdot V_i) V_i. \quad (13) \]
Using Eq. (12) we have \( x = h_i V_i + y_i \), and
\[ y_i \cdot V_j \leq r_{ij}, \quad \forall j \neq i, \quad (14) \]
where \( r_{ij} \equiv h_j - (V_i \cdot V_j) h_i \). Hence, the \( i \)th (D-1)-face can be characterized either in terms of the \( x \) or \( y_i \) coordinates by

\[
\begin{align*}
\begin{cases}
 x \cdot V_i = h_i \\
 x \cdot V_j \leq h_j, \quad \forall j \neq i \\
 y_i \cdot V_i = 0 \\
 y_i \cdot V_j \leq r_{ij}(h, V), \quad \forall j \neq i
\end{cases}
\end{align*}
\]

\( (15) \)

Notice that \( h_{ij} := r_{ij}/\sqrt{1 - (V_i \cdot V_j)^2} \) is the distance of the (D-2)-face (skeleton) \( [\hat{i} \hat{j}] \) from the projection of the origin on the \( i \)th (D-1)-face, where \( [\hat{i} \hat{j}] \) is the intersection set of \( i \)th and \( j \)th (D-1)-faces. Note also that \( [\hat{i} \hat{j}] \) may not exist for certain \( i \) and \( j \). Thus the conditions \( y_i \cdot V_j \leq r_{ij}(h, V) \) are redundant if the \( j \)th (D-1)-face does not intersect with \( i \)th (D-1)-face at a (D-2)-face. In this case the conditions will be excluded in the following discussion acquisitely. Besides, the normal vector \( V_j \) of \( [\hat{i} \hat{j}] \) in the (D-1)-dimensional Euclidean space \( \mathbb{R}^{D-1}_i \) in which the \( i \)th (D-1)-face lies is given by
\[ V_{ij} = \frac{V_j - (V_i \cdot V_j) V_i}{\sqrt{1 - (V_i \cdot V_j)^2}}. \quad (16) \]

Then the \( i \)th (D-1)-face as a (D-1)-polytope in \( \mathbb{R}^{D-1}_i \) can be given by
\[ \mathcal{P}_i(h_i, V_i) := \{ y_i \in \mathbb{R}^{D-1}_i | V_{ij} \cdot y_i \leq h_{ij}, j = 1, \ldots, F_i \}, \quad (17) \]
where \( h_i := (h_{i1}, \ldots, h_{iF_i}) \), \( V_i := (V_{i1}, \ldots, V_{iF_i}) \), and \( F_i \) is the number of the (D-2)-faces as the (D-2)-skeletons of the \( i \)th (D-1)-face (see Fig. 2).

The above procedure of algorithm can be denoted by
\[ \mathbb{L}^D_i : \mathcal{P}(h, V) \Rightarrow \mathcal{P}_i(h_i, V_i). \quad (18) \]
Similarly, we can continue this procedure for (D-1)-polytope \( \mathcal{P}_i(h_i, V_i) \) and get
\[ \mathbb{L}^{D-1}_i : \mathcal{P}_i(h_i, V_i) \Rightarrow \mathcal{P}_{ij}(h_{ij}, V_{ij}), \quad (19) \]

where \( \mathcal{P}_{ij}(h_{ij}, V_{ij}) \) is the \( j \)th (D-2)-face of \( \mathcal{P}_i(h_i, V_i) \), \( V_{ij} = (\ldots, V_{ij}, \ldots) \) is the set of the unit outward normal vectors of the (D-3)-skeletons of \( \mathcal{P}_{ij}(h_{ij}, V_{ij}) \) in the (D-2)-dimensional Euclidean space \( \mathbb{R}^{D-2}_{ij} \) in which \( \mathcal{P}_{ij}(h_{ij}, V_{ij}) \) lies, and \( h_{ij} = (\ldots, h_{ij}, \ldots) \) is the set of distances of the (D-3)-skeletons of \( \mathcal{P}_{ij}(h_{ij}, V_{ij}) \) from the projection of the origin on \( \mathbb{R}^{D-2}_{ij} \). This operation can be continued so that arbitrary \( d \)-dimensional (1 < \( d < D \)) skeletons of the original D-polytope can be obtained. Such a procedure can be illustrated as
\[ \mathbb{L}^{D+1}_{i(d-d)} \circ \cdots \circ \mathbb{L}^{D-1}_{i2} \circ \mathbb{L}^D_{i1} : \mathcal{P}(h, V) \Rightarrow \mathcal{P}_{i1-iD-d}(h_{i1-iD-d}, V_{i1-iD-d}), \quad (20) \]

where we defined
\[ \mathbb{L}^{D+1}_{i(d-d)} : \mathcal{P}_{i1-iD-d-1}(h_{i1-iD-d-1}, V_{i1-iD-d-1}) \Rightarrow \mathcal{P}_{i1-iD-d}(h_{i1-iD-d}, V_{i1-iD-d}), \quad (21) \]

Fig. 2. The \( i \)th and \( j \)th (D-1)-faces in the D-polytope \( \mathcal{P}(A, V) \). The point \( O \) represents the origin of \( \mathbb{R}^D \) where \( \mathcal{P}(A, V) \) lies, and the point \( O_i \) represents the projection of \( O \) on \( \mathbb{R}^D_i \). \( p \) is a point in the \( i \)th (D-1)-face which can be denoted by \( x \) in the coordinate system in \( \mathbb{R}^D \) with origin \( O \) or by \( y_i \) in the coordinate system in \( \mathbb{R}^{D-1}_i \) with origin \( O_i \). [\( [\hat{i} \hat{j}] \) is the intersection set of \( i \)th and \( j \)th (D-1)-faces, \( V_i \) is the normal vector of \( [\hat{i} \hat{j}] \) in \( \mathbb{R}^{D-1}_i \), and \( h_{ij} \) is the distance of \( [\hat{i} \hat{j}] \) from the origin \( O_i \).]
To summarize, for a D-polytope $\mathcal{P}(\mathbf{h}, \mathbf{V})$ defined by (11) with its (D-1)-faces’ outward normals and perpendicular heights given by $\mathbf{V}$ and $\mathbf{h}$ respectively, one can find the corresponding information of an arbitrary d-skeleton of $\mathcal{P}(\mathbf{h}, \mathbf{V})$ following the Lasserre’s reconstruction algorithm, i.e.,

\[
\text{D-polytope } \mathcal{P}(\mathbf{h}, \mathbf{V}) \text{ defined by } \mathbf{V} \text{ and } \mathbf{h} \xrightarrow[]{} \text{Lasserre’s reconstruction algorithm}
\]

Arbitrary $d$-skeleton of $\mathcal{P}(\mathbf{h}, \mathbf{V})$ described by $\mathbf{V}$ and $\mathbf{h}$.

Thus, for the $d$-skeleton of $\mathcal{P}(\mathbf{h}, \mathbf{V})$ labelled by $\hat{i}_1 \cdots \hat{i}_{D-d}$, its $(d-1)$-faces’ outward normals $\mathbf{V}_{i_1 \cdots i_{D-d}}$ and perpendicular heights $\mathbf{h}_{i_1 \cdots i_{D-d}}$ can be expressed by $\mathbf{V}$ and $\mathbf{h}$.

3.2 Area of the d-skeleton

To express the areas of arbitrary skeletons with $(\mathbf{h}_i, V_i)$ of a D-polytope $\mathcal{P}(\mathbf{h}, \mathbf{V})$, let us first consider the 3-dimensional skeletons $\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3}$ in the 3-dimensional Euclidean space. $\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3}$ can be defined by a series of algorithms as

\[
\mathbf{L}^3 \circ \cdots \circ \mathbf{L}^3(\mathbf{i}_1, \mathbf{i}_2, \mathbf{i}_3) \circ \mathbf{L}^3(\mathbf{i}_1, \mathbf{i}_2, \mathbf{i}_3, \mathbf{i}_4) \circ \cdots \circ \mathbf{L}^3(\mathbf{i}_1, \mathbf{i}_2, \mathbf{i}_3, \mathbf{i}_4, \mathbf{i}_5) \circ \cdots 
\]

where $\mathbf{L}^3$ denotes the Lasserre’s reconstruction algorithm.

It has been shown in [7] that the areas of the 2-faces of a 3-polyhedra can be given by the outward unit normal vectors and heights of these 2-faces. Then, by the results of $h_{i_1 \cdots i_{D-d}} = \mathbf{h}_{i_1 \cdots i_{D-d}}(\mathbf{h}, \mathbf{V})$ and $V_{i_1 \cdots i_{D-d}} = \mathbf{V}_{i_1 \cdots i_{D-d}}(\mathbf{h}, \mathbf{V})$ given by (22), the area $\text{Ar}(\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3})$ of this 3-dimensional skeleton can be denoted by

\[
\text{Ar}(\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3}) := \text{Ar}(\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3}) \cdot h_{i_1 \cdots i_{D-d}}(\mathbf{h}, \mathbf{V})
\]

with $\text{Ar}(\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3})$ being the area of the $(\hat{i}_{D-2})$th 2-faces of the 3-polyhedra $\mathcal{P}_{\hat{i}_1 \hat{i}_2 \hat{i}_3}$ as certain function of $(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}})$ [7]. In turn, one can construct the expression of the area of an arbitrary d-face of the D-polytope $\mathcal{P}(\mathbf{h}, \mathbf{V})$ with $\mathbf{h}$ and $\mathbf{V}$. The d-area of a $d$-polytope can be given by adding all the products of its $(d-1)$-faces’ areas and heights and then dividing it by $d$, i.e.,

\[
\text{Ar}(\mathcal{P}_{i_1 \cdots i_{D-d}}(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}})) = \frac{1}{d} \sum_{i=1}^{d} \text{Ar}(\mathcal{P}_{i_1 \cdots i_{D-d+1}}(\mathbf{h}_{i_1 \cdots i_{D-d+1}}, \mathbf{V}_{i_1 \cdots i_{D-d+1}})),
\]

where $\text{Ar}(\mathcal{P}_{i_1 \cdots i_{D-d+1}}(\mathbf{h}_{i_1 \cdots i_{D-d+1}}, \mathbf{V}_{i_1 \cdots i_{D-d+1}}))$ denotes the $(d-1)$-area of $(i_{D-d+1})$th $(d-1)$-face of the $d$-polytope $\mathcal{P}_{i_1 \cdots i_{D-d}}(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}})$, and the sum is taken over all the $(d-1)$-faces of $\mathcal{P}_{i_1 \cdots i_{D-d}}(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}})$. Thus by Eqs. (20), (23), (24), it is easy to see that we can give the areas of arbitrary dimensional skeletons with $(\mathbf{V}, \mathbf{h})$ step by step as

\[
\begin{align*}
A_{j_1 \cdots j_{D-d}}(\mathbf{h}, \mathbf{V}) & \xrightarrow[h_{j_1}]{} A_{j_1 \cdots j_{D-d}}(\mathbf{h}, \mathbf{V}) \xrightarrow[h_{j_1}]{} \cdots \xrightarrow[h_{j_1}]{} A_{j_1}(\mathbf{h}, \mathbf{V}) \xrightarrow[\text{Vol}(\mathcal{P}(\mathbf{h}, \mathbf{V}))]{\text{Vol}(\mathcal{P}(\mathbf{h}, \mathbf{V}))},
\end{align*}
\]

where $A_{j_1 \cdots j_{D-d}}(\mathbf{h}, \mathbf{V}) := \text{Ar}(\mathcal{P}_{i_1 \cdots i_{D-d}}(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}}))$, and $h_{j_1 \cdots j_{D-d}} = \mathbf{h}_{j_1 \cdots j_{D-d}}(\mathbf{h}, \mathbf{V}), \ldots, \mathbf{h}_i = \mathbf{h}_i(\mathbf{h}, \mathbf{V})$ are given by the algorithm (20). Here we have denoted by $A_i$ the area of $i_{\text{th}}$ $(D-1)$-face of $\mathcal{P}(\mathbf{V}, \mathbf{h})$, which satisfies

\[
A_i = A_i(\mathbf{V}, \mathbf{h}), \quad \forall i.
\]

This system of equations can be solved for $h_i(\mathbf{A}, \mathbf{V})$. The existence of a solution with $h_i > 0, \forall i$ is guaranteed by the Minkowski’s theorem. However, the solution is not unique, because of the freedom of moving the origin around inside the polytope and thus changing the value of the heights without changing the shape of the polytope.

Now the reconstruction of a D-polytope with its (D-1)-faces’ areas and normal vectors is ready. For given $(\mathbf{A}, \mathbf{V})$ satisfying Minkowski’s theorem, we can choose a solution of $h_i(\mathbf{A}, \mathbf{V})$ of the system of Eq. (26), and then follow the Lasserres’s reconstruction algorithm and Eqs. (20), (23) and (24) to obtain arbitrary d-dimensional skeletons $\mathcal{P}_{i_1 \cdots i_{D-d}}(\mathbf{h}_{i_1 \cdots i_{D-d}}, \mathbf{V}_{i_1 \cdots i_{D-d}})$ and their d-areas by $(\mathbf{V}, \mathbf{h}(\mathbf{A}, \mathbf{V}))$ step by step. Especially, the D-volume $\text{Vol}(\mathcal{P}(\mathbf{h}(\mathbf{A}, \mathbf{V}), \mathbf{V}))$ as a function of (D-1)-areas and normals has a number of interesting properties as follows. (i) The volume is by construction non-negative. For given (D-1)-areas, it vanishes if and only if the normals $(\mathbf{V}_1, \ldots, \mathbf{V}_F)$ lie in a (D-1)-hyperplane including the special cases of $F < D$. (ii) For fixed (D-1)-areas $\mathbf{A}$, the D-volume is a bounded function of the normals $(\mathbf{V}_1, \ldots, \mathbf{V}_F)$. Let $V_{\text{max}}(\mathbf{A})$ be its maximum volume such that

\[
V_{\text{max}}(\mathbf{A}) \equiv \sup_{\mathbf{V}_F} \text{Vol}(\mathcal{P}(\mathbf{h}(\mathbf{A}, \mathbf{V}), \mathbf{V})).
\]

Then $V_{\text{max}}(\mathbf{A})$ is smaller than the D-volume of the D-ball which has the same (D-1)-surface area as that of the D-polytope. Therefore we have the bound

\[
0 \leq V_{\text{max}}(\mathbf{A}) < \frac{\pi^D}{2^D} \frac{\pi^{D-1}}{2^{D-2}} \frac{D!}{\Gamma \left( \frac{D}{2} + 1 \right)}
\]

where $\Gamma$ is the Leonhard Euler’s gamma function defined by $\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt, x > 0$. (iii) If one sets one of the (D-1)-areas to be zero so that the result is still a non-degenerate D-polytope, the D-volume function $\text{Vol}(\mathcal{P}(\mathbf{h}(\mathbf{A}, \mathbf{V}), \mathbf{V}))$ given by (25) automatically measures
the D-volume of the reduced D-polytope whose (D-1)-faces’ number is $F - 1$.

It should be noted that a pair of $(A, V^{IJ})$ with simplicity condition $V_i^{[IJ} V_j^{KL]} = 0$ determines uniquely the pair of $(A, V^{IJ})$ and hence also the whole geometry of a D-polytope $P(A, V^{IJ})$ in $\mathbb{R}^{D+1}$. To summarize, based on the Lasserre’s reconstruction algorithm, the areas of the 2-dimensional skeletons of a D-polytope $P(A, V^{IJ})$ can be expressed by $h$ and $V^{IJ}$. Then, one can give the areas of arbitrary dimensional skeletons of $P(A, V^{IJ})$ labelled by $(A, V)$ can be extended to the same polytopes $P(A, V^{IJ})$ labelled by $(A, V^{IJ})$ equivalently.

- To summarize, based on the Lasserre’s reconstruction algorithm, the areas of the 2-dimensional skeletons of a D-polytope $P(h, V^{IJ})$ can be expressed by $h$ and $V^{IJ}$. Then, one can give the areas of arbitrary dimensional skeletons of $P(h, V^{IJ})$ with $h$ and $V^{IJ}$ step by step as follows:

\[
\begin{align*}
\text{D-polytope } P(h, V) \text{ defined by } V \text{ and } h & \\
& \xrightarrow{\text{Lasserre’s reconstruction algorithm}} \text{Area of 2-skeletons of } P(h, V) \text{ expressed by } (h, V) \\
& \quad \xrightarrow{\text{Eq. (24)}} \text{Area of } d \text{-skeletons of } P(h(A, V), V) \text{ expressed by } (A, V).
\end{align*}
\]

The areas of (D-1)-faces of $P(h, V^{IJ})$ given by $A = A(h, V^{IJ})$ is a solvable system of equations for $h(A, V^{IJ})$. Then, the areas of arbitrary dimensional skeletons of $P(h, V^{IJ})$ can be expressed by $h(A, V^{IJ})$. In other words, for given $(A, V^{IJ})$ satisfying Minkowski’s theorem and simplicity constraint, one can construct a D-polytope $P(A, V^{IJ})$ with the areas of its arbitrary dimensional skeletons expressed by $A$ and $V^{IJ}$.

### 3.3 Special D-polytopes

The volume of a D-polytope can be expressed by its (D-1)-faces’ areas and normals following the reconstruction procedure. Usually, for an arbitrary D-polytope, this procedure is complicated and the numerical investigation is necessary. To study concrete examples of D-polytopes, we now consider the D-simplex and parallel D-polytope defined by their (D-1)-faces’ areas and normals and give their volume expressions directly.

A D-dimensional simplex is a D-polytope with exactly $D + 1$ vertices. Equivalently, it is the convex hull of a set of affinely independent $D + 1$ points in $\mathbb{R}^D$. Let us consider a D-simplex $P_{\text{Sim}}(A, V^I)$ with its (D-1)-faces’ areas and normals being given by $A = (A_1, \ldots, A_{D+1})$, $V^I = (V_1^I, V_2^I, \ldots, V_{D+1}^I)$ respectively.

The volume of $P_{\text{Sim}}(A, V^I)$ can be given as

\[
\text{Vol}(P_{\text{Sim}}(A, V^I)) = \frac{(D-1)!}{D!} \frac{1}{\sqrt{\det[I - i^J\nu_i^j]}} V_1^I V_2^I \cdots V_{D+1}^I.
\]

where $\nu_i^j$ is the Levi-Civita symbol in $\mathbb{R}^D$ in which $P_{\text{Sim}}(A, V^I)$ locates.

A parallel D-polytope $P_{\text{para}}(A, V^I)$ is a D-polytope whose (D-1)-faces’ number is $2D$, and these (D-1)-faces are parallel in pairs such that $V_i^I = -V_{i+D}^I$, $V_1^I \leq i \leq D$ and each pair of parallel (D-1)-faces has same (D-1)-area, i.e., $A_i^I = A_{i+D}^I$, $V_1^I \leq i \leq D$.

The volume of $P_{\text{para}}(A, V^I)$ can be given as

\[
\text{Vol}(P_{\text{para}}(A, V^I)) = \frac{1}{\sqrt{\det[I - i^J\nu_i^j]}} V_1^I V_2^I \cdots V_{D+1}^I.
\]

As we will see, these expressions are useful when we consider the semi-classical limit of the volume operators for corresponding quantum D-polytopes.

### 4 The meaning of quantum polytope

Based on the classical properties of D-polytope, in the rest of the paper we will discuss the relevance of D-polytope for all dimensional QG. The relation comes from the following observations [14]. First, simple coherent intertwiners are the building blocks of simple spin-network states in all dimensional LQG and contribute a non-orthogonal basis of the vertex kinematic Hilbert space satisfying the simplicity constraint. Second, simple coherent intertwiners space is the quantum correspondence of the shape space of D-polytopes with fixed (D-1)-faces’ areas discussed in previous sections. Therefore the simple coherent intertwiners can be understood as the states of quantum polytope, and simple spin-network states as a collection of quantum polytopes associated with each vertex. In this section we will establish the notion of quantum polytopes and show that a simple coherent intertwiner is peaked at the geometry of a classical polytope.

#### 4.1 The quantum D-polytope

The shape space $\mathcal{P}_A^D$ of D-polytopes composed of the elements in the phase space $Q_{D-1}(A^I)$ of bi-vectors $A_i^I V_i^{IJ}$. To obtain the quantum space corresponding to $\mathcal{P}_A^D$, let us first consider the quantization of $Q_{D-1}(A^I)$. It is helpful to introduce the following geometric quantization example which is closely related to the case that we are considering [22,31].
Consider a particle moving on an unit D-dimensional sphere with energy \( \varepsilon \). The phase space of its angular momentum \( L_{IJ} \) is given by the compact Kahler manifold \( Q_{D-1} \) with Kahler form \( \Omega \). The geometric quantization of this model gives the following condition \([22]\)

\[
\sqrt{2\varepsilon} = N + \frac{D-1}{2}, \quad N = 0, 1, 2, \ldots
\]

which implies the existence of the corresponding quantum Hilbert space \( \mathcal{H}^N(Q_{D-1}, \Omega) \) labelled by quantum number \( N \). The dimension of \( \mathcal{H}^N(Q_{D-1}, \Omega) \) is given by

\[
\dim(\mathcal{H}^N(Q_{D-1}, \Omega)) = \frac{(2N + D - 1)(D + N - 2)!}{(D-1)!N!},
\]

which equals to the dimension of the space \( S^{N, D+1} \) of homogeneous harmonic functions on \( S^D \) with degree \( N \). Thus \( S^{N, D+1} \) is equivalent to \( \mathcal{H}^N(Q_{D-1}, \Omega) \) as the representation space of the quantum algebra of the angular momentum operator \( L_{IJ} = -iX_{IJ} \), which is isomorphic to the Lie algebra \( \text{so}(D + 1) \) and where \( X_{IJ} \) is a \( \text{so}(D + 1) \) valued bi-vector given by \( X_{IJ} = 2\delta_{I}^{[I} \delta_{J]}^{J} \) in the defining representation space of \( \text{SO}(D+1) \). Note that the eigenvalues of \( \text{SO}(D + 1) \) Casimir operator \( \Delta := -1/2X_{IJ}X^{IJ} \) read \( N(N + D - 1) \). Now we can identify \( \sqrt{2\varepsilon}V^{IJ} \) and \( A^2 \) with the angular momentum \( L_{IJ} \) and Casimir operator \( \Delta \) in above example respectively. Then we will get the quantum Hilbert space \( \mathcal{H}^N(Q_{D-1}, \Omega^{A^2/2}) \) of \( Q_{D-1}(A) \) with the condition

\[
A = N + \frac{D-1}{2}, \quad N = 0, 1, 2, \ldots
\]

We can also choose the equivalent quantum Hilbert space \( S^{D+1, N} \). The eigenvalues \( N(N + D - 1) \) of the Casimir operator \( \Delta \) become the spectrum of the operator \( A^2 \) here. Also, the classical bi-vector \( \sqrt{2\varepsilon}V^{IJ} \) is promoted as operator \( -iX_{IJ} \).

As mentioned in Sect. 2, the shape space \( \mathfrak{P}_{\mathcal{A}}^N \) of D-polytopes in \( \mathbb{R}^{D+1} \) is not a phase space but a constraint surface in the phase space \( \mathfrak{P}_{\mathcal{A}} \) given by Eq. (10). Thanks to the Guillemin–Sternberg’s theorem \([32]\), the quantization commutes with the reduction with respected to the closure constraint (6). Hence we can first quantize the unconstrained phase space \( \times_{i=1}^F \mathcal{Q}_{D-1}(A_i) \) and then reduce it at quantum level by extracting the subspace of \( \otimes_{i=1}^F S^{N_i, D+1} \), which is invariant under the global rotations of a D-polytope induced by the closure constraint. This gives precisely the \( \text{SO}(D + 1) \) gauge invariant intertwiner space \( \mathcal{H}_{\mathcal{N}} := \text{Inv}[\otimes_{i=1}^F S^{N_i, D+1}] \) with \( N \) representing the set \( \{N_1, \ldots, N_i, \ldots, N_F\} \). The commutativity is summarized by the following diagram

\[
\begin{align*}
\begin{array}{c}
\times_{i=1}^F Q_{D-1}(A_i) \\
\text{Geometric quantization}
\end{array}
\begin{array}{c}
\otimes_{i=1}^F S^{N_i+1} \\
\text{Sympetic reduction}
\end{array}
\begin{array}{c}
\mathfrak{P}_{\mathcal{A}} \\
\text{Geometric quantization}
\end{array}
\begin{array}{c}
\mathcal{H}_{\mathcal{N}} \\
\text{Quantum reduction}
\end{array}
\end{align*}
\]

The quantization also promote the classical variables \( \sqrt{2\varepsilon}A_i V^{IJ} \) in \( \mathfrak{P}_{\mathcal{A}} \) as operators \( -iX_{IJ} \) acting on elements in \( \mathcal{H}_{\mathcal{N}} \). Then we can impose the simplicity constraint weakly in the quantum space \( \mathcal{H}_{\mathcal{N}} \) by using the so-called coherent intertwiner states composed of the \( \text{SO}(D + 1) \) coherent states of Perelomov type \([14]\). The resulting weak solutions of quantum simplicity constraint constitute the so-called simple coherent intertwiners space \( \mathcal{H}_{\mathcal{N}}^{\mathcal{C}} \), which has the following two important properties \([14]\). (i) The gauge-fixed formulation of its elements, which is called gauge-fixed simple coherent intertwiners, vanishes the expectation values of the quantum simplicity constraint with minimal uncertainty for given quantum numbers \( N \), while the expectation values of the quantum simplicity constraint for the gauge invariant simple coherent intertwiners remain some quantum interference terms that tend to zero in large \( N \) limit. (ii) A simple coherent intertwiner labelled by \( (N, V^{IJ}) \) in \( \mathcal{H}_{\mathcal{N}}^{\mathcal{C}} \) gives a semiclassical \( D \)-polytope, with its \( (D-1) \)-faces’ areas \( A_i \propto \sqrt{N_i} \) and its shape being identical to the classical polytope \( \mathfrak{P}(A, V^{IJ}) \) with minimal uncertainty. Also, each point in the classical phase space \( \mathfrak{P}_{\mathcal{A}} \) corresponds to a simple coherent intertwiner in \( \mathcal{H}_{\mathcal{N}}^{\mathcal{C}} \). In this sense, there is a “Classical-Quantum correspondence” between \( \mathfrak{P}_{\mathcal{A}} \) and \( \mathcal{H}_{\mathcal{N}}^{\mathcal{C}} \).

The quantization and the weak imposition of simplicity constraints can be summarized by the following diagram

\[
\begin{align*}
\begin{array}{c}
\mathfrak{P}_{\mathcal{A}} \\
\text{Impose } V^{IJ}V^{KL} = 0,
\end{array}
\begin{array}{c}
\mathcal{H}_{\mathcal{N}}^{\mathcal{C}} \\
\text{Correspondence}
\end{array}
\end{align*}
\]
\[
8\sqrt{2\pi\beta l_p^{(D+1)}}^{D-1} i X_{i}^{IJ}.
\] (34)

The operator \(i X_{i}^{IJ}\) is self-adjoint with its domain being given by \(\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{N_i, D+1}\). Accordingly the closure constraint and simplicity constraint are promoted formally to operator equations,
\[
\sum_{i=1}^{F} A_{i} V^{IJ}_{i} = 0 \quad \iff \quad \sum_{i=1}^{F} X_{i}^{IJ} = 0,
\] (35)
\[
V^{[IJ}_{i} V^{KL}_{j}] = 0 \quad \iff \quad X^{[IJ}_{i} X^{KL}_{j}] = 0.
\] (36)

For the consideration of quantum D-polytopes, Eqs. (A.21) and (36) correspond to quantum Gaussian constraint and vertex simplicity constraint in (1+D)-dimensional LQG respectively. One can then proceed to associate operators to geometric observables through the quantization map (34). The area of a (D-1)-face of the quantum polytope is defined as
\[
\hat{A}_{i} = \beta \kappa \hbar \sqrt{-\frac{1}{2} X_{i}^{IJ} X_{i, IJ}},
\] (37)

wherein the operator \(X_{i}^{IJ} X_{i, IJ}\) in the square root is positive and self-adjoint in the space \(\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{N_i, D+1}\) and hence its square root is defined by its spectrum projection. The eigenvalues of \(\hat{A}_{i}\) is given by
\[
A_{i} = 16\pi\beta (l_p^{(D+1)})^{D-1} \sqrt{N_i(N_i + D - 1)}.
\] (38)

Similar to the case in standard (1+3)-dimensional LQG, the scalar product between the \(SO(D+1)\) generators associated to two (D-1)-faces of a D-polytope measures the angle \(\theta_{ij}\) between them, i.e.,
\[
\theta_{ij} = \arccos \frac{\frac{1}{2} X_{i}^{IJ} X_{j, IJ}}{N_i(N_i + D - 1)(N_j(N_j + D - 1))}
\] (39)

defined in \(\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{N_i, D+1}\). Also, the operator \(X_{i}^{IJ} X_{j, IJ}\) is self-adjoint in the space \(\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{N_i, D+1}\) and hence the arc cosine in the right-hand side of (39) is defined by its spectrum projection. Notice that the angle operators do not commute among themselves. Therefore it is impossible to find a state for a quantum D-polytope with definite values of all the angles between its (D-1)-faces. Moreover, the adjacent relations of the (D-1)-faces are not prescribed a priori. Thus Eq. (39) might not even be a true dihedral angle of the D-polytope.

4.2 Simple coherent intertwiner

The simple coherent intertwiners are defined as the \(SO(D+1)\)-invariant projection of a tensor product of states \(|N_i, V^{IJ}_{i}\rangle\)
\[\in \mathcal{S}_{N_i}^{D+1,N_i}\] i.e.,
\[
|\langle N, V^{IJ}\rangle| = \int_{SO(D+1)} dg \otimes_{i=1}^{F} g |N_i, V^{IJ}_{i}\rangle
\] (40)

where \(|\langle N, V^{IJ}\rangle| \equiv \otimes_{i=1}^{F} |N_i, V^{IJ}_{i}\rangle\) is the gauge-fixed simple coherent intertwiner such that the closure constraint and simplicity constraint are weakly satisfied. Here the states \(|N_i, V^{IJ}_{i}\rangle\) are \(SO(D+1)\) coherent states of Perelomov type satisfying the peakedness property [33]
\[
\langle N_i, V^{IJ}_{i} | X^{IJ} | N_i, V^{IJ}_{i} \rangle = 2i N_i V^{IJ}_{i},
\] (41)

and the relative uncertainty
\[
\frac{|\Delta(< X^{IJ} >>)|}{|< X^{IJ} >|} = \frac{D-1}{\sqrt{N}}.
\] (42)

It is clear that Eq. (42) tends to zero for \(N \rightarrow \infty\) [33]. The expectation values of the geometric operators composed of the flux operators with respect to the simple coherent intertwiners \(|\langle N, V^{IJ}\rangle|\) have the nice property of semiclassicality. For example, the expectation values of the non-commuting angle operators \(\hat{\theta}_{ij}\) reproduce the classical angles between (D-1)-faces of the D-polytope in the large \(N\) limit as
\[
\frac{|\langle N, V^{IJ}\rangle| \cos \hat{\theta}_{ij} |\langle N, V^{IJ}\rangle|}{|\langle N, V^{IJ}\rangle|} \approx V^{IJ}_{i} V^{IJ}_{j},
\] (43)

and the dispersions are small in comparison with the expectation values.

An useful property of gauge invariant coherent intertwiners is that they provide a over-complete basis of the gauge invariant intertwiner space. This can be seen as follow. It has been shown that the building block \(|N, V\rangle\) of the coherent intertwiner provides a resolution of identity in the space \(\mathcal{S}_{N_i}^{D+1,N_i}\) as
\[
\dim(\mathcal{S}_{N_i}^{N_i}) \int_{Q_{i-1}} dV |N, V\rangle \langle N, V| = \mathbb{1}_{\mathcal{S}_{N_i}^{D+1,N_i}}.
\] (44)

Thus it can be extended as a resolution of identity in the space \(\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{N_i}\) as
\[
\left( \prod_{i=1}^{F} \dim(\mathcal{S}_{N_i}^{N_i}) \right) \int_{Q_{i-1}} \ldots \int_{Q_{1-1}} dV_i |N, V\rangle \langle N, V| = \mathbb{1}_{\otimes_{i=1}^{F} \mathcal{S}_{N_i}^{D+1,N_i}}.
\] (45)

Such a resolution of identity also exists in the gauge invariant coherent intertwiner space. To simplify the realization of this resolution, we can suppose a parametrization of the phase space \(\mathcal{P}_A\). The phase space structure ensures that we can parametrize \(\mathcal{P}_A\) via \(2F(D-1) - D(D+1)\) real numbers \(Z\).
Hence the gauge invariant coherent intertwiner $|N, V^{IJ}\rangle$ satisfying $\sum_{i=1}^{2} N_i V^{IJ} = 0$ can be rewritten as $|N, Z\rangle$ with $Z$ representing the equivalent class (up to the globe $SO(D+1)$ rotation) of $V^{IJ}$. Then, we can immediately introduce the resolution of identity in the gauge invariant coherent intertwiner space $\mathcal{H}_N$ as

$$\mathbb{I}_{\mathcal{H}_N} = \int_{\mathfrak{A}} d\mu(Z) |N, Z\rangle \langle N, Z|,$$  \tag{46}

where $d\mu(Z)$ is the measure on $\mathfrak{A}$ which is compatible with the symplectic structure, whose existence will be shown in Appendix A.

Moreover, some similar tasks about the shape space of 3-polyhedra and its quantization have been studied in $SU(2)$ LQG, where one considered the $SU(2)$ coherent intertwiners [34–39]. More explicitly, the shape space of 3-polyhedra in $SU(2)$ LQG is a phase space, which can be given by reducing the space of 2-faces’ normals with respect to the closure constraint (Gaussian constraint) without simplicity constraint. Especially, the shape space of 3-polyhedra can be parametrized by the so-called cross-ratio variables, which is invariant under the $SU(2)$ transformation. It is natural to construct such cross-ratio variables in the general D-polytopes case, to give the explicit expression of the variables $Z$ in (45).

However, this construction is not intuitive and we leave this problem to further research.

5 General geometric operators

The simple coherent intertwiner space is regarded as the quantum space of D-polytopes, and the geometric properties of these quantum polytopes should be given by geometric operators defined in this space. Two kinds of general spatial geometric operators based on the basic holonomy and flux operators in all dimensional LQG have been defined in [21]. Notice that the shape space of D-polytopes is the constraint surface of simplicity constraint in $\mathfrak{A}$. Thus, the quantum state must solve the simplicity constraint correctly, to ensure that the geometric operators catch proper quantum degrees of freedom of D-polytope. We consider the weak imposition of the anomalous quantum simplicity, which gives the simple coherent intertwiner space. However, such a treatment is only well-behaved for large $N$. How to deal with the simplicity constraint is still an open issue in small $N$ cases.

In fact, the general geometric operators with respect to D-polytopes can also be defined by the coherent states of spatial geometry such as the gauge invariant coherent intertwiners. Also, the definition of such kind of geometric operators provides us a new method to deal with the simplicity constraint. The geometric operators of quantum polytopes involving coherent states can be constructed based on following two facts: (i) A simple coherent intertwiner state is labelled by a point of the shape space of D-polytopes with fixed (D-1)-faces’ areas, and the corresponding wave function is peaked at this point. (ii) A point in the shape space of D-polytopes gives full geometric information of the corresponding D-polytope. Thus, a distribution which selects simple coherent intertwiner and reveals the corresponding geometric degrees of freedom is the key ingredient in this construction. Let us construct such functions $G(A, Z)$ and corresponding geometric operators as follows.

Consider the shape space $\mathfrak{P}_A$. Recall that the phase space $\mathfrak{P}_A$ is parametrized via $2 F(D - 1) - D(D + 1)$ real numbers $Z$. They induce the coordinates of the space $\mathfrak{P}_A$ of dimension $F(D - 1) - D(D + 1)$, where these parameters $Z$ have to satisfy $n = F(D - 1) - D(D + 1)$ independent equations $S_1 = 0, ..., S_n = 0$ corresponding to the simplicity constraint. We denote by $\tilde{Z}$ the independent parameters of $Z$ that can parametrize the points in $\mathfrak{P}_A$. For an arbitrary point $p \in \mathfrak{P}_A$, with parameters $\tilde{Z}_p$, there is an equivalent class (up to global $SO(D+1)$ rotations) of the set $V^I_J$ satisfying the closure and simplicity conditions. However, the gauge invariant simple coherent intertwiner $|N, V^{IJ}\rangle$ is independent of the gauge choice of $V^{IJ}$ and hence it can be equivalently denoted by $|N, \tilde{Z}\rangle$ with $\tilde{Z}$ or the equivalent class of $V^{IJ}$ representing the same point in $\mathfrak{P}_A$. Now, let us consider certain geometric quantity $G$, such as the length, area or volume and so on, of certain skeletons of the D-polytopes given by points of $\mathfrak{P}_A$. The geometric quantity $G$ is a function $G(A, \tilde{Z})$ on $\mathfrak{P}_A$, and its expression can be given by the reconstruction procedures introduced in Sect. 3. However, the integral in the identity (46) takes over the space $\mathfrak{P}_A$ which contains the points without any D-polytope meaning. To overcome the obstacle, one could extend the function $G(A, \tilde{Z})$ to take value on whole space $\mathfrak{P}_A$ as

$$G(A, \tilde{Z}) \mapsto G(A, Z),$$  \tag{47}

where $G(A, Z)$ is a proper distribution peaked at the subspace $\mathfrak{P}_A^\epsilon$ such that

$$G(A, Z)|_{Z=\tilde{Z}} = G(A, \tilde{Z}), \quad G(A, Z)|_{Z \neq \mathfrak{P}_A^\epsilon} = 0$$  \tag{48}

and

$$0 \leq G(A, Z) \leq \sup_{\mathfrak{P}_A^\epsilon}[G(A, \tilde{Z})],$$

where $\mathfrak{P}_A^\epsilon$ with “width” $\epsilon \in \mathbb{R}_+$ is an open neighbourhood of $\mathfrak{P}_A$ in $\mathfrak{P}_A$, which satisfies

$$\lim_{\epsilon \to 0} \mathfrak{P}_A^\epsilon = \mathfrak{P}_A.$$

Note that the extension (47) may take different choices, which could lead different treatments of the simplicity constraint. We will get back to this point latter.
Now the geometric operator related to $G$ can be defined in the simple coherent intertwiner space $\mathcal{K}_{N}^{t.c.}$ by [40]

$$\hat{G} = \int_{\mathcal{P}_{A}} d\mu(Z) G(A, Z) |N, Z\rangle\langle N, Z|$$

(50)

with $A_{i} = 16\pi\beta l_{p}^{(D+1)}N_{i}^{2}\sqrt{N_{i} + D - 1}$. Note that $\mathcal{K}_{N}^{t.c.}$ is a sub-Hilbert space of the gauge invariant coherent intertwiner space $\mathcal{K}_{N}$. Thus the matrix element of (50) selected by states $|N, \tilde{Z}_{1}\rangle, |N, \tilde{Z}_{2}\rangle \in \mathcal{K}_{N}^{t.c.}$ involves the inner product $\langle N, Z | N, \tilde{Z}_{1} \rangle$ and $\langle N, Z | N, \tilde{Z}_{2} \rangle$ in $\mathcal{K}_{N}$, which is given by

$$\langle N, \tilde{Z}_{1} \hat{G} | N, \tilde{Z}_{2} \rangle$$

$$= \int_{\mathcal{P}_{A}} d\mu(Z) G(A, Z) |N, \tilde{Z}_{1} | N, Z \rangle \langle N, Z | N, \tilde{Z}_{2} \rangle.$$  

(51)

It has been shown that $|\langle N, Z | N, \tilde{Z}_{1} \rangle|$ sharply peaked at $Z = \tilde{Z}_{1} \in \mathcal{P}_{A}$ in large $N$ limit [33]. Hence, the integral in (51) only concerns the behaviour of $G(A, Z)$ on $\mathcal{P}_{A}$.

$$V(A, V^{IJ}(Z)) = \sqrt{\frac{D-1}{D}}^{D-1} \frac{(D - 1)!!}{D!} \frac{1}{\sqrt{A_{1}...A_{D}}} \prod_{i=1}^{D} \left| \epsilon_{H_{i1}...H_{iD}} V_{1}^{H_{i1}} V_{2}^{H_{i2}} V_{3}^{H_{i3}}...V_{D}^{H_{iD}} \delta_{K_{1}K_{3}}...\delta_{K_{D-1}K_{D}} \right|^{2}.$$  

(53)

However, this peakedness property of $|\langle N, Z | N, \tilde{Z}_{1} \rangle|$ is not valid for small $N$ cases. Then the behaviour of $G(A, Z)$ outside $\mathcal{P}_{A}$ becomes important. Because of Eq. (48), though the integral in (51) is taken over $\mathcal{P}_{A}$, only specific coherent intertwiners selected by the distribution $G(A, Z)$ contribute to this integral. These selected coherent intertwiners labelled by the points in $\mathcal{P}_{A}$ (e) include all of the simple coherent intertwiners. Besides, the simple coherent intertwiner only weakly satisfies the quantum simplicity constraint and thus its quantum perturbation breaks this satisfaction. The behaviour of the distribution $G(A, Z)$ on $\mathcal{P}_{A}$ (e) and the choice of (e) determine how the quantum perturbations of the simple coherent intertwiner contribute to the integral in (51). Hence, we may control the influence of quantum perturbations of the simple coherent intertwiner by the choices of the extension (47), even in the small $N$ cases.

Another useful application of the geometric operators constructed by (50) is the semi-classical consistency check. By definition, the geometric operators involving coherent states constructed by (50) have the desired semiclassical property in large $N$ limit. Note that in one of the two strategies proposed in Ref. [21] the geometric operators are totally composed of flux and volume operators. They are also expected to have well semiclassical behaviours for simple coherent intertwiners. We will take the volume as an example to compare the semiclassical properties of its different operator versions.

5.1 D-volume operator of quantum D-polytopes

The volume of D-polytopes is a well-defined function on their shape space $\mathcal{P}_{A}$. Let $V(A, V^{IJ}(\tilde{Z}))$ be the volume of a D-polytope with (D-1)-faces of areas $A_{i} = 16\pi\beta l_{p}^{(D+1)}N_{i}^{2}\sqrt{N_{i} + D - 1}$ and unit normal bi-vectors $V^{IJ}(\tilde{Z})$ (up to $SO(D + 1)$ rotations). Consider the space $\mathcal{K}_{N}^{t.c.}$ of simple coherent intertwiners corresponding to the shape space $\mathcal{P}_{A}$. The volume of quantum polytopes can be defined in terms of the gauge invariant coherent intertwiners $|N, Z\rangle$ and of the classical volume as [40]

$$\hat{V} = \int_{\mathcal{P}_{A}} d\mu(Z) V(A, Z) |N, Z\rangle\langle N, Z|,$$  

(52)

where the distribution $V(A, Z)$ on $\mathcal{P}_{A}$ is the extension of volume function $V(A, V^{IJ}(\tilde{Z}))$ on $\mathcal{P}_{N}$ following (47), which is also restricted by $0 \leq V(A, Z) \leq \sup_{\mathcal{P}_{N}} V(A, \tilde{Z}) \equiv V_{\text{max}}(A)$. For instance, in the case that $\mathcal{P}_{A}$ describes even $D + 1$ oriented (D-1)-faces, the distribution $V(A, Z)$ on $\mathcal{P}_{A}$ can be defined as

$$\hat{V} = \int_{\mathcal{P}_{A}} d\mu(Z) V(A, Z) |N, Z\rangle\langle N, Z|,$$  

(52)

By substituting the solution $V^{ij}_{ij} = \sqrt{\frac{D}{D-i}})^{D-i}$ of simplicity constraint into (53), it is easy to check that $\hat{V}(A, V^{IJ}(Z))$ gives the volume expression (29) of D-simplex on the simplicity constraint surface. In fact, a specific choice of this extension $V(A, V^{IJ}(\tilde{Z})) \mapsto V(A, Z)$ following (47) relies on a concrete treatment of the quantum perturbations of simple coherent intertwiner. Nevertheless, the property of $\hat{V}$ is independent of the choice of this extension in large $N$ limit. We will focus on the large $N$ limit case.

The D-volume operator in $\mathcal{K}_{N}^{t.c.}$ has following interesting properties in large $N$ limit. First, using the fact that two coherent intertwiners become orthogonal in large $N$ limit [33], one can show that the expectation value of $\hat{V}$ for a coherent intertwiner $|N, \tilde{Z}\rangle$ reproduces the volume of the classical polytope with shape $(A, \tilde{Z})$ in large $N$ limit, i.e.,

$$\langle \hat{V} \rangle \equiv \langle N, \tilde{Z} | \hat{V} | N, \tilde{Z} \rangle \xrightarrow{N \to \infty} V(A, \tilde{Z}).$$  

(54)

Second, it can be proven that the operator $\hat{V}$ is positive semi-definite. Consider arbitrary state $|\phi\rangle \in \mathcal{K}_{N}^{t.c.}$. Since

$$\langle \phi | \hat{V} | \phi \rangle = \int_{\mathcal{P}_{A}} d\mu(Z) V(A, Z) |\langle N, Z | \phi \rangle|^{2} \geq 0.$$  

(55)

This is a straightforward consequence of the fact that the classical volume $V(A, \tilde{Z})$ is a positive function. Moreover,
\(\hat{V}\) vanishes for \(F < D + 1\). Third, \(\hat{V}\) is a bounded operator in \(H^{\infty,\eta}_N\). Its norm \(||\hat{V}|| = \sup_{\phi} (\phi|\hat{V}|\phi)/(|\phi|\phi)\) is bounded by the maximum value of the classical D-volume of a D-polytope with fixed (D-1)-faces’ areas, i.e.,

\[
\frac{(\phi|\hat{V}|\phi)}{(\phi|\phi)} = \int d\mu(Z) V(A,Z) |(N,Z|\phi)|^2 \\
\leq \sup_{\phi}(V(A,\bar{Z})) \equiv V_{max}(A),
\]

(56)

where \(V_{max}(A)\) is bounded by the D-volume of the D-ball whose (D-1)-sphere surface’s (D-1)-area is given by \(\sum_{i=1}^{F} A_i\). Moreover, suppose that the operator \(\hat{V}\) is defined in the Hilbert space \(H^{\infty,\eta}_N\) corresponding to the quantum D-polytopes with \(F + 1\) (D-1)-faces associated to quantum numbers \((N_1, ..., N_F)\). In the case of \(N_F = 0\) and \(F > D\), it coincides with the volume operator in \(H^{\infty,\eta}_N\) corresponding to the quantum D-polytopes with \(F + 1\) (D-1)-faces associated to quantum numbers \((N_1, ..., N_F)\). This is a consequence of the fact that the classical volume of a D-polytope with \(F + 1\) (D-1)-faces coincides with the volume of a D-polytope with \(F\) (D-1)-faces and the same normal vectors, if one of the areas of the faces in the former is set to zero.

5.2 The usual D-volume operator

Since the spin network states labelled by coherent intertwiners are well-behaved coherent states for flux operator [14,33], it is natural to discuss the semi-classical property of the usual D-volume operator defined in all dimensional LQG based on flux operators [12]. The usual strategy of constructing D-volume operator in all dimensional LQG is based on the semiclassical D-polytopes, the (1+3)-dimensional theory to fixe this pre-factor and a consistency based on the semiclassical D-polytopes, the pre-factor can be fixed case by case. This can be demonstrated by following two samples.

In the first sample, we consider the semiclassical behaviours of the D-volume operator \(\hat{V}^{B.T.}(R)\) based on D-parallelepiped. In this case, the “semiclassical” states for spatial geometry are based on the D-hypercubic graph \(\gamma\) dual to the D-parallelepiped. Such D-hypercubic graph is equipped with 2D-valent vertices, and the tangent vectors of the edges linked to a same vertex \(v\) span a D-dimensional vector space at \(v\) so that they are parallel in pairs (see Fig. 3).

The states are “semiclassical” in the sense that a coherent intertwiner is chosen on each vertex of the graph \(\gamma\) underlying the states. More precisely, the “semiclassical” states are chosen such that, (i) each pairs of edges linked to same vertex \(v\) with parallel tangent vectors at \(v\) are labelled with same quantum numbers \(N_j = N_{j+D}, \ j = 1, \ldots, D\), and (ii) each vertex is labelled with a gauge invariant simple coherent intertwiner \(|N, V_{IJ}\rangle_p\) peaked at a point of \(P_K\), which corresponds to a parallel D-polytope with \(A_j = 16\pi \beta(p^{(D+1)}D-1)\sqrt{N_j(N_j + D - 1)}, \ N_j = N_{j+D}\) and \(V_{IJ} = -V_{IJ}\), \(j = 1, \ldots, D, \ D\). Let \(R(v)\) be a sufficiently small open region dual to the vertex \(v\). Then, according to the calculations in [33], the expectation value of the D-volume \(\bar{V}_{R(v)}\) with respect to \(|N, V_{IJ}\rangle_p\), reads at zeroth order of \(\hbar\) as

\[
\langle \bar{V}_{R(v)} \rangle = (\hbar \beta) \frac{D}{D!} \frac{1}{\beta^D} \left( \frac{\varphi_{\text{reg}}}{2D!} \right)^D -1
\]

\[\psi_n\] Springer
Fig. 3 is the unit vector satisfying
\[ e^\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD} V_{i1}V_{i2}V_{i3}...V_{iD} \]
\( v \) of (D-1)-faces of the parallel D-polytope that span the D-polytope with \( v \) of the (D-1)-areas and normals, its expression simplifies greatly for parallel D-polytopes as discussed in section 3.

For \( D = 2n + 1 \) is odd, and
\[ \langle \hat{\mathcal{V}}_{\gamma}(v) \rangle = \frac{\hbar \beta}{D^D} \]
\( \left( \frac{\sqrt{D} \epsilon_{\text{reg.}}}{D!} \prod_{j=1}^{D} N_j \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} V_{i1}V_{i2}V_{i3}...V_{iD} \right)^{1/D} \]
\( (60) \)

For \( D = 2n \) is even, where \( \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} \) is the unit vector satisfying \( N^I \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} = 0, \forall i = 1, ..., 2D \), and \( V_{i1}, V_{i2}, ..., V_{iD} \) is the D independent normal vectors of (D-1)-faces of the parallel D-polytope that span the D-dimensional vector space orthogonal to \( N^I \). Notice that the variables \( (\mathbf{N}, \mathbf{V}^I) \) labelling the simple coherent intertwiner correspond to the variables \( (\mathbf{A}, \mathbf{V}^I) \) defining a D-polytope around the vertex \( v \). Although the volume of a convex D-polytope with \( F \) faces is in general a rather complicated function of the (D-1)-areas and normals, its expression simplifies greatly for parallel D-polytopes as discussed in section 3.

The volume of a parallel D-polytope is
\[ \text{Vol}(\mathcal{P}_{\text{para}}(\mathbf{A}, \mathbf{V}^I)) = -1 \prod_{i=1}^{D} \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} V_{i1}V_{i2}V_{i3}...V_{iD} \]
\( (62) \)

Thus, in order to match the expectation value \( (60) \) and \( (61) \) of D-volume operator \( \langle \hat{\mathcal{V}}_{\gamma}(v) \rangle \) with respect to \( ||\mathbf{N}, \mathbf{V}^I||_p \), with the classical volume \( (62) \) of the D-polytope, the regularization factor in the D-volume operator \( (57) \) should be given by \( \epsilon_{\text{reg.}} = D! \) in the case of the D-hypercubic graphs. In the second sample, we consider the semiclassical behaviour of D-volume operator \( \hat{\mathcal{V}}_{\gamma}(v) \) based on D-simplexes (see Fig. 4).

In this case the simple coherent intertwiners \( ||\mathbf{N}, \mathbf{V}^I||_p \) at the (D+1)-valent vertices \( v \) satisfy \( \sum_{i=1}^{D+1} N_i V_{i}^I = 0 \) and \( V_{i}^J = \sqrt{2} N_{i}^I V_{i}^I \), where the normal vectors \( \{V_{i}^I\} \) span a D-dimensional vector space. Then, according to the calculation in [33], the expectation value of \( \langle \hat{\mathcal{V}}_{\gamma}(v) \rangle \) with respect to \( ||\mathbf{N}, \mathbf{V}^I||_p \) reads at zero order of \( \hbar \) as,
\[ \langle \hat{\mathcal{V}}_{\gamma}(v) \rangle = \frac{\hbar \beta}{D! \sqrt{D}} \frac{(D+1)^D (\text{reg.})}{D^D} \]
\( \left( \prod_{j=1}^{D} N_j \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} V_{i1}V_{i2}V_{i3}...V_{iD} \right)^{1/D} \]
\( = \frac{(\hbar \beta)^D}{D! \sqrt{D} \epsilon_{\text{reg.}}} \frac{(D+1)^D (\text{reg.})}{D^D} \]
\( \left( \prod_{j=1}^{D} N_j \hat{f}_{\gamma_{i1}\gamma_{i2}\gamma_{i3}...e_{iD}} V_{i1}V_{i2}V_{i3}...V_{iD} \right)^{1/D} \]
\( (63) \)
for $D = 2n + 1$ is odd, and

$$\hat{V}_{R(\epsilon)} = (\hbar \kappa_\beta)^{D-1} \left( \frac{D+1}{D\sqrt{2}} \right)^{D-1} \left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

for $D = 2n$ is even. The semiclassical consistency requires that the expectation value (63) and (64) be equal to the volume

$$\text{Vol}(\mathcal{P}_{\text{Sim}}(\mathbf{A}, \mathbf{V}^{IJ})) = \frac{(D - 1)!}{D!} D \prod_{j=1}^{D} \frac{1}{\sqrt{\eta_1 \cdots \eta_D}} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right)$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

$$\left( \prod_{j=1}^{D} N_j \epsilon_1 \epsilon_2 \cdots \epsilon_D \epsilon_{\bar{j}} \right) \left( \frac{D}{2D} \right)^{\frac{3}{2}} \sqrt{\eta_1 \cdots \eta_D} \left( \hat{V}_1 \hat{V}_2 \cdots \hat{V}_D \right) \right) \right)^{\frac{1}{2}}$$

of the classical D-simplex $\mathcal{P}_{\text{Sim}}(\mathbf{A}, \mathbf{V}^{IJ})$, where $A_i = 16 \pi \beta (D+1)^{D-1} \sqrt{\eta_1 \cdots \eta_D}$ is the (D-1)-area of its $\bar{i}$th (D-1)-face. Then, the regularization factor in the D-volume operator (57) should be fixed as

$$c_{\text{reg}} = \frac{2^D}{(D + 1)(D)! D - 2}$$

in the case of D-simplexes.

The simple coherent intertwiners provide a useful tool to study the semi-classical property of usual D-volume operator in large $N$ limit. Based on the expectation value of the usual D-volume operator with respect to the spin network states labelled by the specific simple coherent intertwiners, we have shown above that the un-determined regularization factor can be fixed by requiring the semi-classical consistency. It should be noted that the classical counterpart of the usual D-volume operator is an analytic function on the un-constrained holonomy-flux phase space [44]. Once the Gaussian and simplicity constraints are solved, this classical counterpart captures the correct geometric meaning of the D-volume of some D-polytope. However, in quantum theory, the vertex simplicity constraint becomes anomalous and is weakly solved based on the coherent intertwiners. We notice that the usual D-volume operator does not commute with the vertex simplicity constraint operator, and the quantum perturbations of the simple coherent intertwiners break the satisfaction of vertex simplicity constraint significantly for small $N$ [14,33]. Thus, the simple coherent intertwiners would introduce some non-physical degrees of freedom to the usual D-volume operators in small $N$ cases. In comparison to the usual D-volume operator, the expression of the coherent state D-volume operator given by (50) and (52) contains a cut-off introduced by the second equation in (48), which restricts the contribution of the quantum perturbations of the simple coherent intertwiners to the integral in (50). Hence, the coherent state D-volume operator is preferable in small $N$ cases.

### 6 Summary and discussion

In previous sections a number of properties of D-polytopes have been introduced. A D-polytope can be uniquely identified by the areas and the normals of its (D-1)-faces. Hence the shape space $\mathcal{P}_{\mathcal{A}}$ of D-polytopes was defined by Eq. (5) through the areas and bi-vector normals of their (D-1)-faces. This shape space was then extended as the phase space $\mathcal{P}_{\mathcal{A}}$ by neglecting the simplicity constraints, so that the quantization was achieved. We also introduced the Lasserre’s reconstruction algorithm as expression (20) and discussed how to derive explicitly the areas of $d$-skeleton of a D-polytope from the (D-1)-areas and normals through the reconstruction procedure as (25). Some general properties of the D-volumes of D-polytopes were given, and the volumes of D-simplex and parallel D-polytope were discussed in details.

The relevance of D-polytopes to the quantum theory was the main issue which we discussed. The geometric quantization of the phase space $\mathcal{P}_{\mathcal{A}}$ was transferred to shape space $\mathcal{P}_{\mathcal{A}}^{\mathcal{S}}$ by imposing weakly the quantum simplicity constraints. The result is the gauge invariant simple coherent intertwiner space whose elements can be interpreted as coherent states of D-polytopes. The knowledge of the simple coherent intertwiners corresponding to D-polytopes and the Lasserre’s reconstruction algorithm were then used to define a new kind of spatial geometric operators by Eq. (50) including the areas of $d$-skeletons ($1 \leq d \leq D$) of a quantum D-polytope. By construction these new operators have the correct semiclassical limit. We compared the new version of D-volume operator based on the D-polytope with the one usually constructed in all dimensional LQG. It was shown by two examples that the consistent semiclassical limit of the usual volume operator with respect to the semiclassical D-polytopes can be obtained by fixing its undetermined regularization factor case by case.

The relation between classical shape space of D-polytopes and gauge invariant simple coherent intertwiner space is remarkable. Similar to the studies for standard (1+3)-dimensional LQG [45–47], it is hopeful to extend this relation so that one could geometrically parametrize the phase space underlying all dimensional LQG [44,48,49]. Also, the semiclassical consistency check for D-volume operator is expected to be extended to other spatial geometric operators. Note that, the general spatial geometric operators in [21] were constructed by the building block operator, whose action on a quantum state depends on the actions of the basic flux and holonomy operators, while the spatial geometric...
operators (50) involve the coherent intertwiners as well as the classical geometry of D-polytopes. Thus, a prior, there is no guarantee that the two constructions of a same geometric quantity would give a same operator. However, if one restrict the actions of the different versions of a geometric operator on the semiclassical states based on the graph dual to a D-polytopes, it is possible to check their semiclassical operator on the semiclassical states based on the graph dual.

Regarding the restrictions, there is no guarantee that the two constructions of a same geometric quantity would give a same operator. However, if one restrict the actions of the different versions of a geometric operator on the semiclassical states based on the graph dual to a D-polytopes, it is possible to check their semiclassical consistency. The notion of quantum D-polytopes may shed a new light on further developments of all dimensional LQG.

Appendix A: The complex structure on the Kahler manifold $Q_{D-1}$

The compact Hermitian symmetry space $Q_{D-1} = SO(D+1)/(SO(D-1) \times SO(2))$ can be defined as a subspace of the D-dimensional complex projective space $\mathbb{C}P^D$, which reads

$$Q_{D-1} = \{(z_1, \ldots, z_{D+1}) \in \mathbb{C}P^D : \sum_{j=1}^{D+1} z_j \bar{z}_j = 0\}. \quad (A.1)$$

The space $\mathbb{C}P^D$ is defined by

$$\mathbb{C}P^D = \{z = (z_1, \ldots, z_{D+1}) \in \mathbb{C}^{D+1} \setminus \{0\} : |z| = cz, \quad c \in \mathbb{C} \setminus \{0\}\} \quad (A.2)$$

and the standard Hermitian metric on $\mathbb{C}^{D+1}$ is given by

$$ds^2 = dz_1 \otimes d\bar{z}_1 + \cdots + dz_{D+1} \otimes d\bar{z}_{D+1} \quad (A.3)$$

which gives the standard Euclidean metric on $\mathbb{R}^{2D+2}$ by realification. The quotient $\mathbb{C}P^D \rightarrow \mathbb{C}P^D$ can be realized in two steps. One first define

$S^{2D+1} = \{z \in \mathbb{C}^{D+1} \setminus \{0\} : |z| = rz, \quad r \in \mathbb{R}_+\}. \quad (A.4)$

and then obtain

$\mathbb{C}P^D = \{z \in S^{2D+1} : |z| = e^{\theta z}\}. \quad (A.5)$

The Fedini-Study metric is the metric induced on $\mathbb{C}P^D = S^{2D+1}/\mathbb{S}^1$ with the metric on $S^{2D+1}$ given by restriction of the standard Euclidean metric on $\mathbb{R}^{2D+2}$ to $S^{2D+1}$. The complex structure $J$ on $\mathbb{C}P^D$ satisfies

$$J \left( \frac{\partial}{\partial x_I} \right) = \frac{\partial}{\partial y_I}, \quad J \left( \frac{\partial}{\partial y_I} \right) = -\frac{\partial}{\partial x_I} \quad (A.6)$$

with $z_I = x_I + iy_I$. Then, the induced complex structure together with the Fedini-Study metric give the Kahler form on $\mathbb{C}P^D$. All these structures can be further restricted to the space $Q_{D-1}$.

The phase space of a free particle moving in $\mathbb{R}^{2D+1}$ is given by $\mathbb{C}P^D$ with the standard Kahler form $\sigma$. By restricting this particle moving on a unit D-sphere $S^D$, one gets the reduced phase space

$$P_A = \{n^I \in \mathbb{R}^{D+1}, AV^I \in \mathbb{R}^{D+1} | n^I n_I = V^I V_I = 1, n_I V_I = 0, A \in \mathbb{R}_+\} \quad (A.7)$$

with the form $\sigma = \sum_{I=1}^{D+1} d(n^I) \wedge d(AV^I)$ restricting to $P_A$. We focus on the angular momentum of this particle with fixed velocity $A$, which constitutes the phase space

$$Q_{D-1}(A) = \{AV^I = \sqrt{2A}n^I V_I; (n^K, AV^L) \in P_A\} \quad (A.8)$$

and the Poisson bracket (4) among $AV^I$ can be given by the form $\sigma [33,50]$. It is easy to see that the action of $SO(D+1)$ on $Q_{D-1}(A)$ is transitive and thus the tangent vector fields on $Q_{D-1}(A)$ can be labelled by the Lie algebra $so(D+1)$. Denoted by $\tau^I$ the tangent vector fields on $Q_{D-1}(A)$ labelled by $\tau^I = \delta^I_L \delta^K \delta^L_J \in (so(D+1))_{\text{def.}}$. The induced complex structure $J$ on $Q_{D-1}(A)$ satisfies

$$J(\alpha_{IJ} \tau^I) \left|_{AV^I \in Q_{D-1}(A)} \right. = \sqrt{2A} \alpha^I_J V^I_L \tau^L \left. |_{AV^I \in Q_{D-1}(A)} \right. \quad (A.9)$$

Now we can extend the action of $Spin(D+1)$ as the universal cover group of $SO(D+1)$ on $\Omega_A := Q_{D-1}(A_1) \times \cdots \times Q_{D-1}(A_F)$ to an action of $Spin(D+1)_C$, which is generated by the complexified Lie algebra $so(D+1) + \mathbb{R}(D+1)$, on $\Omega_A$ by defining

$$i\alpha_{IJ} \tau^I \mapsto (i\alpha_{IJ} \tau^I) \in T\Omega_A \quad (A.10)$$

with

$$i\alpha_{IJ} \tau^I = J(\alpha_{IJ} \tau^I), \quad (A.11)$$

where $i\alpha_{IJ} \tau^I \in \mathbb{R}(D+1)$, and $T\Omega_A$ denotes the set of the tangent vector fields on $\Omega_A$. Further, this extension
of the action can be realized for the coherent intertwiner $|N, V\rangle$ labelled by the element in $\Omega_A$. Given an element $H := \exp(i \alpha^{IJ} \tau_{IJ}) \in Spin(D + 1)_C$, one has

$$H|N, V\rangle = \rho_H^N(V)|N, V_H\rangle$$

(A.12)

where

$$\rho_H^N(V) = e^{-\alpha N}, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} = \sqrt{2} \alpha V^{IJ},$$

$$\rho_H^N(V) = 1, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} V_{IJ} = 0$$

and otherwise the action (A.12) follows the infinite small averaging on the gauge variant ones ant coherent intertwiner $\exp$. Where

$$\rho_H^N(V) = e^{-\alpha N}, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} = \sqrt{2} \alpha V^{IJ},$$

$$\rho_H^N(V) = 1, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} V_{IJ} = 0$$

Now let us project the identity (45) to the gauge invariant coherent intertwiner $A := Spin(D + 1)_C \cdot |N, V\rangle$, labelled by the element in $\Omega_A$. Given an element $H := \exp(i \alpha^{IJ} \tau_{IJ}) \in Spin(D + 1)_C$, one has

$$H|N, V\rangle = \rho_H^N(V)|N, V_H\rangle$$

(A.12)

where

$$\rho_H^N(V) = e^{-\alpha N}, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} = \sqrt{2} \alpha V^{IJ},$$

$$\rho_H^N(V) = 1, \quad V_H = V, \quad \text{for} \quad \alpha^{IJ} V_{IJ} = 0$$

and otherwise the action (A.12) follows the infinite small transformation given by (A.10). Recall that the gauge invariant coherent intertwiner $|N, V\rangle$ can be given by taking group-averaging on the gauge variant ones $|N, V\rangle$. Since the coherent intertwiner is holomorphic on $\Omega_A$ with $A$ being given by (38), this invariance extends to the $Spin(D + 1)_C$ action, which gives

$$|N, V_H\rangle = \rho_H^N(V)|N, V\rangle, \quad H \in Spin(D + 1)_C$$

(A.13)

where $\rho_H^N(V) = \prod_{i=1}^F \rho_H^N(V_i)$. Let $|N, V\rangle$ be the norm of $|N, V\rangle$ such that $\langle N, V|N, V\rangle = ||N, V||^2$. Then the function $|N, V\rangle$ on $\Omega_A$ satisfies

$$(\alpha^{IJ} \tau_{IJ})|N, V\rangle = -\sqrt{2} \alpha_{IJ} C_{IJ}||N, V||,$$

$$(\alpha^{IJ} \tau_{IJ})(\beta_{IJ} \tau_{IJ}) \ln |N, V\rangle = -G^{IJKL}_{N,V} \alpha_{IJ} \beta_{KL},$$

where $C_{IJ} := \sum_{i=1}^F N_i V_{IJ}^i$ is the closure condition and $G^{IJKL}_{N,V}$ is the metric on the orbits $Spin(D + 1)_C \cdot (N, V)$, which reads

$$G^{IJKL}_{N,V} := \sum_{i=1}^F N_i (\delta^{[I|K]} \delta^{J|L} - \delta^{I|K} \delta^{J|L}),$$

(A.15)

It follows that the maximum of $||N, V||$ occurs on the constraint surface $\Omega_A^{(0)} := \{N, V\} \in \Omega_A |C_{IJ} = 0\}$. Hence we can conclude the result of Guillemin-Sternberg as

$$\Omega_A^{(s)} := Spin(D + 1)_C \cdot \Omega_A^{(0)} = \{N, V\} \in \Omega_A^{(0)} \cap \{||N, V|| \neq 0\},$$

(A.16)

Note that $Spin(D + 1)_C$ preserves the space $\Omega_A^{(0)}$. By defining $\mathcal{B} := Spin(D + 1)_C/Spin(D + 1)$, one has

$$\mathcal{B} := \Omega_A^{(0)} \times Spin(D + 1)_C/Spin(D + 1) = \Omega_A^{(0)} \times \mathcal{B}.$$ 

(A.17)

Now let us project the identity (45) to the gauge invariant intertwiner space as

$$\int_{\Omega_A} dV_N|N, V\rangle|N, V\rangle = \mathbb{I}_{N,N}$$

(A.18)
