A Proteomic Analysis Reveals That Snail Regulates the Expression of the Nuclear Orphan Receptor Nuclear Receptor Subfamily 2 Group F Member 6 (Nr2f6) and Interleukin 17 (IL-17) to Inhibit Adipocyte Differentiation

Alberto Peláez-García‡, Rodrigo Barderas§, Raquel Batlle¶, Rosa Viñas-Castells¶, Rubén A. Bartolomé‡, Sofía Torres‡, Marta Mendes‡, María Lopez-Lucendo‡, Rocco Mazzolini¶, Félix Bonilla, Antonio García de Herreros¶, and J. Ignacio Casal‡**

Adipogenesis requires a differentiation program driven by multiple transcription factors, where PPARγ and C/EBPβ play a central role. Recent findings indicate that Snail inhibits adipocyte differentiation in 3T3-L1 and murine mesenchymal stem cells (mMSC). An in-depth quantitative SILAC analysis of the nuclear fraction of Snail-induced alterations of 3T3-L1 cells was carried out. In total, 2251 overlapping proteins were simultaneously quantified in forward and reverse experiments. We observed 574 proteins deregulated by Snail1 using a fold-change ≥1.5, with 111 up- and 463 down-regulated proteins, respectively. Among other proteins, multiple transcription factors such as Trip4, OsmR, Nr2f6, Cbx6, and Prrx1 were down-regulated. Results were validated in 3T3-L1 cells and mMSC cells by Western blot and quantitative PCR. Knock-down experiments in 3T3-L1 cells demonstrated that only Nr2f6 (and Trip4 at minor extent) was required for adipocyte differentiation. Ectopic expression of Nr2f6 reversed the effects of Snail1 and promoted adipogenesis. Because Nr2f6 inhibits the expression of IL-17, we tested the effect of Snail on IL-17 expression. IL-17 and TNFα were among the most up-regulated pro-inflammatory cytokines in Snail-transfected 3T3-L1 and mMSC cells. Furthermore, the blocking of IL-17 activity in Snail-transfected cells promoted adipocyte differentiation, reverting Snail inhibition. In summary, Snail inhibits adipogenesis through a down-regulation of Nr2f6, which in turn facilitates the expression of IL-17, an anti-adipogenic cytokine. These results would support a novel and important role for Snail and Nr2f6 in obesity control. Molecular & Cellular Proteomics 14: 10.1074/mcp.M114.045328, 303–315, 2015.

Adipogenic differentiation is driven by a complex cascade of transcription factors (TFs)1 and cell signaling molecules that lead to the expression of the master regulators CCAAT/enhancer-binding protein (C/EBP) (1) and peroxisome proliferator-activated receptor (PPAR) (2) family proteins. In a sequential process, C/EBPδ and C/EBPβ are initially induced and followed by C/EBPγ expression. These two master TFs induce the final program of gene expression for adipocyte differentiation.

The transcription factor Snail1 is a major inducer of the epithelial-mesenchymal transition (EMT) during embryonic development and cancer progression (3, 4). Snail1 expression is very restricted in adult individuals (5), but reappears to drive the EMT process that confers promigratory, invasive, and stem cell properties to cancer epithelial cells (4). During this process, Snail represses the expression of E-cadherin and promotes the expression of mesenchymal genes like vimen-

1 The abbreviations used are: TF, transcription factor; Cbx6, chromobox homolog 6; C/EBP, CCAAT/enhancer-binding protein; DAVID, Database for Annotation, Visualization and Integrated Discovery; EMT, epithelial-mesenchymal transition; IL-17, interleukin 17; mMSCs, murine mesenchymal stem cells; Nr2f6, Nuclear Receptor Subfamily 2 Group F Member 6 (Nr2f6); OsmR, oncostatin M receptor; PPAR, peroxisome proliferator-activated receptor; Prrx1, paired related homeobox 1, qPCR, quantitative PCR; RLU, relative luminescence units; SILAC, stable isotopic labeling amino acids in culture; Trip4, thyroid hormone receptor interactor 4.
Snail1 Induces IL-17 Expression to Inhibit adipogenesis

Recent reports indicate that Snail ectopic expression in murine mesenchymal stem cells (mMSCs) abrogated their differentiation to osteoblasts or adipocytes, whereas Snail depletion accelerated them (6). In addition, Snail1 knockdown caused a large decrease in the number of bone marrow mMSCs. This depletion comes accompanied by an acceleration of their differentiation to osteoblasts or adipocytes (6). Moreover, Snail1 regulates osteoblast differentiation through the inhibition of different proteins including Runx2 and vitamin D receptor (7), which indicates an antagonist role for Snail1 and vitamin D (8, 9).

The 3T3-L1 is a preadipocyte fibroblast cell line commonly used for the study of molecular mechanisms controlling adipogenesis (10, 11). Alike mMSCs, confluent 3T3-L1 preadipocytes differentiate to adipocytes upon exposure to a mixture of adipogenic inducers (10). Upon adipogenic differentiation, Snail expression is almost negligible in 3T3-L1 cells (12). Snail1 ectopic expression inhibits the adipocyte differentiation program (6, 12). Snail effect on adipogenesis was proposed to be mediated, among others, by activation of AKT (6) and was associated to an apparent inhibition of PPARγ and C/EBPα expression (12). Similar results were obtained in preventing the differentiation of bone marrow-derived mMSCs to osteoblasts or adipocytes (6). Still, the molecular mechanisms underlying the effect of Snail on 3T3-L1/MSCs differentiation and the blocking of adipogenesis remain unclear.

Here, we investigated the transcriptional control by Snail1 blocking 3T3-L1 differentiation to adipocytes. To this end, we carried out an in-depth quantitative proteomic analysis of 3T3-L1 Snail1-transfected cells using stable isotopic metabolic labeling (SILAC) (13). We focused our proteomic analysis on the nuclear fraction. In total, we identified 574 proteins deregulated, with most of them down-regulated by Snail1. To prove the nuclear fraction. In total, we identified 574 proteins deregulated, with most of them down-regulated by Snail1. To prove

**EXPERIMENTAL PROCEDURES**

**Cell Culture and Adipocyte Differentiation Assays**—Preadipocytes 3T3-L1 and mMSCs were stably transfected with 6 μg of either pcDNA3 Snail1-HA ("snail") or control pcDNA3 ("mock") using lipofectamine (Invitrogen, Carlsbad, CA). Cells were selected with G418 (1 mg/ml) for 3–4 weeks as described (6). Then, stably transfected 3T3-L1 and mMSC cells were grown in DMEM (Invitrogen) containing 10% FBS (Biological Industries, Kibbutz Beit Haemek, Israel), 1 mM L-glutamine, 100 units/ml penicillin-streptomycin, and supplemented with 0.5 μg/ml G418 at 37 °C in 5% CO2.

For adipocyte differentiation, 3T3-L1 cells were plated at a concentration of 1 x 10^6 cells per well, in p60 plates, and cultured for 3 days. Differentiation was induced by the addition of 0.5 mM isobutylmethyl-xanthine, 2 mM dexamethasone, and 1.7 mM insulin. The induction medium was removed after 2 days and cells were supplemented with DMEM plus 10% FBS and 1.7 mM insulin and the medium was replenished after 3 days. When needed, cells were treated with anti-IL-17 antibody (500 ng/ml) (R&D Systems, Minneapolis, MN) every 2 days. For Oil Red O staining, cells were washed gently with PBS twice, fixed with 3.7% formaldehyde in PBS for 1 h at room temperature and stained for 1 h with filtered Oil Red O solution (1.8 mg/ml in 60% isopropanol). Solution was removed and plates rinsed with water and dried prior to image collection.

**SILAC Cell Culture and Nuclear Protein Extracts Preparation**—For metabolic labeling, 3T3-L1 Snail1 or control cells were grown and maintained in DMEM containing either light L-lysine and L-arginine or heavy [13C6]-L-lysine and [13C6]-L-arginine (Dundee Cell Products, Dundee, UK) supplemented with 10% dialyzed FBS, 100 units/ml of penicillin/streptomycin, and 0.5 μg/ml G418 at 37 °C in 5% CO2. Eight duplications were necessary to achieve >97% incorporation of the heavy amino acids (14) calculated for individual proteins as previously described (15). We carried out forward and reverse experiments to get a biological replicate and avoid labeling bias in the study.

For nuclear protein extraction, cells were washed twice with chilled PBS, resuspended with PBS containing 4 mM EDTA, and harvested by centrifugation. At 500 g for 5 min. Then, we used the "Subcellular protein fractionation kit" (Pierce, Rockford, IL). Protein quantification was performed using the tryptophan method (16). Then, 25 μg of protein from nuclear cell extracts were mixed at a 1:1 ratio and run at 25 mA per gel in 12.5% SDS-PAGE. Gels were stained with colloidal coomassie blue and lanes were cut into 18 slices. Excised bands were cut into small pieces and destained with 50 mM ammonium bicarbonate/50% acetonitrile (ACN), dehydrated with ACN, and dried. Gel pieces were rehydrated with 12.5 ng/μl trypsin in 50 mM ammonium bicarbonate and incubated overnight at 30 °C. Peptides were extracted at 37 °C using ACN and then 0.5% TFA, dried, cleaned using ZipTip with 0.6 μl C18 resin (Millipore, Billerica, MA), and reconstituted in 5 μl 0.1% formic acid/2% ACN, prior to MS analysis, which was performed as previously described (17).

**Mass Spectrometry Analysis, Protein Identification, and SILAC Quantification**—Peptides were trapped onto a 2 cm C18-A1 ASY-Column (Thermo Fisher Scientific, Waltham, MA), and then eluted onto a Biosphere C18 column (10 cm long, inner diameter 75 μm, 3 μm particle size) (NanoSeparations, Nieuwkoop, The Netherlands) and separated using a 170 min gradient from 0–35% Buffer B (Buffer A: 0.1% formic acid/2% ACN; Buffer B: 0.1% formic acid in ACN) at a flow-rate of 300 nL/min in a nanoEasy HPLC (Proxeon, Odense, Denmark) coupled to a nano-electrospray ion source (Proxeon). Mass spectra were acquired on an LTQ-Orbitrap Velos mass spectrometer (Thermo-Scientific) in the positive ion mode. Full-scan MS spectra (m/z 400–1200) were acquired in the Orbitrap with a target value of 1,000,000 at a resolution of 60,000 at m/z 400 and the 15 most intense ions were selected for collision induced dissociation (CID) fragmentation in the linear ion trap with a target value of 10,000 and normalized collision energy of 35%. Precursor ion charge state screening and monoisotopic precursor selection were enabled. Singly charged ions and unassigned charge states were rejected. Dynamic exclusion was enabled, with a repeat count of one and exclusion duration of 30s. Mass spectra (.raw) files were searched against the SwissProt mouse database 57.15 (16230 sequences) using MASCOT search engine v. 2.3 (Matrix Science, London, UK) through Proteome Discoverer (version 1.4.1.14) (Thermo). Search parameters included a 30 ppm precursor mass tolerance and 0.8 Da, respectively. Identified peptides were validated using Percolator algorithm with a q-value threshold of 0.01. For each SILAC pair,
Snail1 Induces IL-17 Expression to Inhibit adipogenesis

Proteome Discoverer determines the area of the extracted ion chromatogram and computes the “heavy/light” ratio. Protein ratios are then calculated as the median of all the unique quantified peptides belonging to a certain protein. The ratios among proteins in their heavy and light versions were used as fold-change. Proteins were quantified with at least one peptide hit in forward and reverse experiments. The fold change cutoff for deregulated proteins was calculated using a permutation-based test as described (18). Proteins with quantification variability >20% were manually inspected by checking the isotopic envelope of both heavy and light forms and how many peaks of the envelope were used to determine the area of the envelope of all PSMs corresponding to the peptides used to identify the protein. A multipoint normalization strategy was applied to normalize the data sets against the 5% trimmed mean values, which is a robust statistical measure of central tendency that normalize most of the log₂ protein ratios to 0. Briefly, the 5% of the most extreme outliers–values were removed and the mean of the 95% remaining data was determined, and used to normalize the ratio values, and thus, minimizing the effect of these extreme outliers and centering the log₂ ratio distribution to zero. Because metabolic conversion arginine/proline can affect quantification accuracy in some cell types, we investigated arginine to proline conversion in 3T3-L1 cells. Using heavy proline as a variable modification, less than 1% of proline-containing peptides were heavy labeled in 3T3-L1 cells. The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium (19) via the PRIDE partner repository with the data set identifier PXD001529.

Western Blot Analysis—Protein extracts from 3T3-L1 and mMSC cells were prepared as described (20). Briefly, 25 μg of each protein extract were run in parallel using 10% SDS-PAGE. For immunoblotting, proteins were transferred to nitrocellulose membranes (Hybond-C extra) using wet transfer (Bio-Rad, Hercules, CA, USA). After blocking, membranes were incubated at optimized dilutions with primary antibodies followed by incubation with either HRP-anti-mouse IgG (Pierce) or HRP-anti-rabbit IgG (Sigma, Madrid, Spain) at 1:5000 dilution. Specific reactive proteins were visualized with SuperSignal West Pico Maximum Sensitivity Substrate (Pierce). Snail antibody was used as described (5). A total of 21 different antibodies were used (supplemental Table S1).

RNA Extraction, Semi-quantitative, and Real-time Quantitative PCR—RNA was extracted from cell lines with the RNaseasy Mini Kit (Qiagen, Limburg, The Netherlands) and quantified with a NanoDrop ND-1000 spectrophotometer (Thermo Fisher Scientific). CDNA was synthesized using the Superscript III First Strand Synthesis kit (Invitrogen). For semiquantitative reverse transcriptase-PCR (RT-PCR), reactions were performed using specific primers for each gene (supplemental Data S1). The PCR products were separated on 2% agarose gel and stained with GelRed (Biotium, Hayward, CA). Quantitative PCR (qPCR) analysis was performed using specific primers (supplemental Data S1) and SYBR-Green Master PCR mix (Bio-Rad) in triplicate. Data collection was performed on an IQ5 (Bio-Rad). All quantitations were normalized using mouse 18s rRNA as internal control.

Luciferase Assay—Different promoter regions were obtained by PCR amplification. Primers were designed to generate fragments of ~1000 bp (supplemental Data S1). In all cases, the reverse primers were at positions: +277/+297. The amplified fragments were: pTriP4−650/+277, pNR2f6−700/+269, pOSmR−700/+297, pPRx1−680/+287, and pCBx6−681/+293. They were digested using Mulu and XhoI restriction sites, inserted into pGL3-Luc and sequenced. We used a pGL3 vector containing the −178/+92 fragment of the E-cadherin (CDH1) promoter as a reference. Luciferase protein expression, in terms of relative luminescence units (RLU), was determined using a luciferase assay kit (Promega, Madison, WI) at 24h post-transfection using a Glomax Reader (Promega). Luciferase expression in all transfections was calculated and normalized with the protein content and expressed as RLU per μg. The protein content was determined using the 2D-Quant kit (GE Healthcare, Madrid, Spain).

Chromatin Immunoprecipitation Assay—ChIP experiments were performed as described (21). Briefly, mMSC-Snail cells were cross-linked with 1% formaldehyde for 10 min at 37 °C. Cross-linking was stopped by adding 0.125 M glycine for 2 min at room temperature. Cell monolayers were scraped in cold lysis buffer (50 mM Tris, pH 8.0, 10 mM EDTA, 0.1% Nonidet P-40, and 10% glycerol), and incubated 20 min on ice. Nuclei pellets were lysed with 1% SDS, 10 mM EDTA, and 50 mM Tris, pH 8.0, and extracts were sonicated. Supernatants were diluted 1:10 with dilution buffer, and immunoprecipitation was done overnight at 4 °C using an anti-Snail antibody or an irrelevant antibody. DNA was purified with GFX kit (GE Healthcare) and eluted in MilliQ water. Promoter regions were analyzed by quantitative PCR with SybrGreen staining (Roche, Basel, Switzerland) using the oligonucleotides indicated in supplemental Data S1.

siRNA Transfections—siRNAs for Snail1, Nr2f6, Prx1, Trip1, Cbx6, and controls were purchased from Sigma. For siRNA transfections, cells were transfected with 27.5 pmol siRNA using 1 μl JetPrime Transfection reagent (Polyplus Transfection, Illkirch, France) in 100 μl of JetPrime buffer. Then, cells were grown in p60 culture plates with complete culture medium and used as indicated. For adipocyte differentiation assays after siRNA transfection, cells were grown 48 h with complete culture medium after transfection and, then, adipocyte differentiation was performed as above.

Cloning and Transfections of Nr2f6—Nr2f6 cDNA (clone # MGC-6088 IMAGE:3582557) was obtained from the IMAGE-MGC collection. The cDNA was amplified by PCR with the Advantage 2 polymerase (Clontech, Paris, France) using the primers: 5'-AGGAAATTCACTGGCATGGTTAGGGAAGGTCCTTCCCGGCAGCGACAGACAGG-3' and 5'-CCGGGTACCTAGAAGGGCATAGG-3'. The PCR product was digested with EcoRI and Kpn1 and cloned into pcDNA3.1 (Invitrogen). Nr2f6 cloning was confirmed by DNA sequencing. Cells were transfected with pcDNA3.1/Nr2f6 or empty vector using JetPrime. After 24–48h, transiently transfected cells were lysed and the expression of Nr2f6 was analyzed by Western blot and qPCR.

Cell Proliferation—For cell proliferation assays, experiments were carried out using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide) (Sigma) as described (22).

Cytokine Array and ELISA—Conditioned medium from 3T3-L1 or mMSC cells, mock, or Snail1-transfected, was collected after 48 h in serum-free medium and incubated with the Mouse Cytokine Antibody Array 3 (RayBiotech, Norcross, GA) containing 62 murine cytokine specific antibodies. Then, membranes were scanned and analyzed using Redfin, a 2D-gel image analysis software (Ludesi, Malmo, Sweden) as described (23). Relative cytokine intensities were normalized in comparison to control spots on the same membrane and represented in arbitrary units. Individual quantification of murine IL-17 was carried out with an ELISA kit (RayBiotech).

Bioinformatics and Statistical Analysis—Ingenuity Pathway Analysis (IPA) (Ingenuity Systems, Redwood City, CA) was used to predict biological functions and protein interaction analysis. DAVID Database was used to evaluate the enrichment of nuclear proteins in our proteomic data set (24). For evaluation of the statistical significance compared between groups, all p values were derived from a two-tailed statistical test with 95% confidence interval. p values <0.05 were considered statistically significant. All statistical analyses were done with Microsoft Office Excel.

RESULTS

Protein Alterations in Nuclear Extracts of Snail1-transfected 3T3-L1—Overexpression of Snail1 in 3T3-L1 and mMSC cells was confirmed by Western blot (Fig. 1A). For comparison
purposes, we tested Snail1 and the active fibroblasts marker S100A4 expression at different confluence levels (50, 80, and 100%). As fibroblast activation depends on cell–cell contact, Snail1 expression increased gradually and was maintained 48 h after confluence, conditions suitable for these cells to be differentiated to adipocytes. These conditions were selected for proteomic analysis (Fig. 1B). 3T3-L1 cells (Snail-transfected and mock) were grown and maintained in light and heavy-labeled DMEM medium supplemented with 10% dialyzed FBS. The quality of the subcellular fractionation was assessed by Western blot before mass spectrometry. Cytoplasmic and nuclear fractions were assayed using Lamin B and Rho GDI as nuclear and cytoplasmic protein controls, respectively. E, Proteins identified and quantified in 3T3-L1 forward and reverse SILAC experiments. In total, we identified 3920 proteins with 2800 overlapping proteins, whereas we quantified 3483 proteins with 2251 common proteins in both experiments. F, The enrichment of nuclear fraction with cellular component analyses was evaluated using DAVID Database. In total, 458 out of 2251 quantified proteins in 3T3-L1 were previously observed in nucleus.

Snail1 Induces IL-17 Expression to Inhibit adipogenesis

Fig. 1. Study of protein alterations in nuclear extracts of Snail1 transfected 3T3-L1 cells. A, Verification of Snail1 overexpression in 3T3-L1 and mMSC cells by Western blot analysis. B, 3T3-L1/Snail1 and 3T3-L1/Mock cells were analyzed at indicated cell confluence. The abundance of Snail1 and S100-A4 was quantified by Western blot. Tubulin was used as loading control. According to the results, cell confluence was set up at 100% for 48 h for the rest of the experiments. C, Schematic representation of proteomics experiments with 3T3-L1 cells. For metabolic labeling, 3T3-L1/Snail1 or control cells were grown and maintained in light and heavy-labeled DMEM medium supplemented with 10% dialyzed FBS. D, The quality of the subcellular fractionation was assessed by Western blot before mass spectrometry. Cytoplasmic and nuclear fractions were assayed using Lamin B and Rho GDI as nuclear and cytoplasmic protein controls, respectively. E, Proteins identified and quantified in 3T3-L1 forward and reverse SILAC experiments. In total, we identified 3920 proteins with 2800 overlapping proteins, whereas we quantified 3483 proteins with 2251 common proteins in both experiments. F, The enrichment of nuclear fraction with cellular component analyses was evaluated using DAVID Database. In total, 458 out of 2251 quantified proteins in 3T3-L1 were previously observed in nucleus.
Network and Pathways Alterations Induced by Snail—Among other functions, Snail-deregulated proteins were involved in chromatin remodeling such as Hmga2, Top2A (up-regulated), or chromobox proteins such as CBX1, 3, 5 (up-regulated), 6 and 8 (down-regulated) (Fig. 2A) (supplemental Table S2). Most of the quantified proteins were down-regulated such as OsmR (oncostatin M receptor) and transcription factors like Stat1, Stat3, NFkB, Trip4, Nr2f6, Prrx1, and Sra1 (a component of the ribonucleoprotein complex coactivator NCOA1). Src-related proteins, such as c-Src, Fam120A, Sh3bp1, Lipb1, and Tln1 were also down-regulated, as well as β-catenin, Gsk3β, Rsk6, and Yap1, which have been described to inhibit cell differentiation.

Ingenuity Pathway Analysis (IPA) database was used to identify the predicted pathways and biological functions most significantly altered because of the ectopic expression of Snail. The mTOR pathway, EIF2 signaling, RAN signaling, PI3/AKT signaling, integrin, and cytokine/chemokine signaling were among the top altered pathways (Fig. 2B). Regarding adipogenesis mediators, Snail caused an increase in the levels of C/EBPβ in 3T3-L1. In addition, IPA predicted a down-regulation of PPARγ and up-regulation of C/EBPβ mediators that are critical for the inhibition of final differentiation to adipocytes in 3T3-L1 cells.

Validation and Analysis of Adipogenesis-related Proteins—An initial validation of Snail-deregulated proteins was performed by PCR and Western blot in 3T3-L1 and mMSC

Snail1 Causes a Direct Regulation of Multiple Transcription Factors—*In silico* analysis with MatInspector revealed putative Snail1 E-box consensus motifs in 28 promoters of the quantified proteins (supplemental Table S3). We focused our study on TFs modulated by Snail. To analyze the effect of Snail on these TFs, we carried out a luciferase assay using the repression of the E-cadherin promoter as a control (Fig. 3D). Snail inhibited the luciferase promoter activity for Trip4, Nr2f6, OsmR, and Prrx1 genes, and only slightly that for Cbx6. Compared with E-cadherin, highest repression was observed for Prrx1 and Trip4, similar for Nr2f6 and lower for Cbx6 and OsmR.

By Western blot, we confirmed the down-regulation of phosphoRPS6, phospho mTOR, and elf3D for mTOR signaling, Akt, pAkt, Stat3, pStat3, Fam120A, Talin1, pSrc, and Src for cell signaling alterations, and transcription factors Yap1, Sra1, Prrx1, Trip4, Nr2f6, and Cbx6 (Fig. 3F). In general, differences were more visible in 3T3-L1 than in mMSC cells, probably because of the higher expression of Snail1 in 3T3-L1 transfected cells. We also confirmed the activation of phosphoAkt in Snail-expressing cells as previously reported (6). Akt phosphorylation was observed at Ser-473, which is regulated by mTORC2 activation (26). This result suggests that the observed mTOR inhibition corresponds mainly to mTORC1, involved in RPS6 and not in Ser-473 AKT phosphorylation. Moreover, as a consequence of mTORC1 down-regulation, the elf3 complex and other downstream regulators of mTORC1-RPS6 pathway such as RPS6 and Erk1 were also down-regulated in Snail1-transfected cells (27, 28).

Snail1 Causes a Direct Regulation of Multiple Transcription Factors—*In silico* analysis with MatInspector revealed putative Snail1 E-box consensus motifs in 28 promoters of the quantified proteins (supplemental Table S3). We focused our study on TFs modulated by Snail. To analyze the effect of Snail on these TFs, we carried out a luciferase assay using the repression of the E-cadherin promoter as a control (Fig. 3D). Snail inhibited the luciferase promoter activity for Trip4, Nr2f6, OsmR, and Prrx1 genes, and only slightly that for Cbx6. Compared with E-cadherin, highest repression was observed for Prrx1 and Trip4, similar for Nr2f6 and lower for Cbx6 and OsmR.

The binding of Snail to the promoters of these transcription factors was confirmed using a ChiP assay. Chromatin samples were immunoprecipitated with a specific antibody against Snail1 in comparison to an irrelevant antibody as control. We used PTEN as positive control of Snail regulation (6, 21). Snail was recruited to all the tested promoters containing E-box motifs, showing a greater binding for Trip4, Nr2f6, OsmR, and Prrx1 genes, and only slightly that for Cbx6. Compared with E-cadherin, highest repression was observed for Prrx1 and Trip4, similar for Nr2f6 and lower for Cbx6 and OsmR.

Down-regulation of Nr2f6 Controls Adipogenic Differentiation—To further evaluate the role of these TFs on adipocyte differentiation, we knocked down Prlx1, Nr2f6, Trip4, and Cbx6 expression in wild-type 3T3-L1 cells using specific
siRNAs. Changes in lipid content after culturing cells with differentiation mixture were detected visually in entire culture plates and microscopically representative fields (Fig. 4A) or quantitatively by colorimetry of Oil Red staining (Fig. 4B). There was a strong inhibitory effect caused by the loss of Nr2f6 in adipocyte differentiation.Trip4 effects were minor, but still significant. Snail1 expression levels remained unaffected after Nr2f6 silencing (Fig. 4C). In addition, an increase of Nr2f6, maintaining similar Snail1 expression levels, was observed during 3T3-L1/Snail1 differentiation (Fig. 4D). By qPCR, the levels of Nr2f6 and the master adipogenic mediators PPARγ and C/EBPα were down-regulated by Snail1 expression when compared with 3T3-L1 mock cells, except C/EBPβ that was not repressed by Snail (Fig. 4E). Collectively, these results suggest an important role for Nr2f6 in adipocyte differentiation.

**Overexpression of Nr2f6 Promotes Adipogenesis**—Conversely, to further address the positive role of Nr2f6 in adipogenesis, we ectopically expressed Nr2f6 in 3T3-L1/Mock and 3T3-L1/Snail cells. We adjusted conditions of transfection (1 μg/5 × 10⁶ cells) to avoid an excessive cell death caused by Nr2f6 overexpression. Enhanced expression of Nr2f6 did not alter Snail1 levels of expression as detected by Western blot and qPCR (Fig. 5A–5B). By qPCR, we observed a large increase of expression of Nr2f6 in transfected cells accompanied by an important increase of C/EBPα and C/EBPβ in

**Fig. 3. Validation of Snail1-deregulated proteins in 3T3-L1 and mMSC cells by PCR and Western blot.** A, cDNA synthesized from total RNA from 3T3-L1/Snail1 and control cells was subjected to semi-quantitative RT-PCR. Data represent the median and S.D. of three independent experiments. C, Nuclear protein extracts of 3T3-L1/Snail1, mMSC/Snail1, and control cells were subjected to Western blot using specific antibodies against the indicated proteins. Lamin B was used as nuclear and loading control. D, 3T3-L1/Snail1 and control cells were transfected with the amplified promoters cloned in the pGL3 plasmid. E-cadherin promoter was used as control. Data represents the mean of Firefly luciferase ± S.E. of three independent experiments performed on triplicate. **: p < 0.005; ***: p < 0.001 compared with control cells. E, To confirm the regulation of these transcription factors by Snail1, we performed ChIP assay using a specific anti-Snail1 antibody. PTEN was used as positive control of Snail1 regulation. An irrelevant IgG was used as negative control. Data represent the median/mean ± S.D. of the results. F, Western blot analysis of the reversion of the expression of the indicated transcription factors by knockdown of Snail1. Lamin B was used as loading control.
3T3-L1/Mock cells. Snail1 ectopic expression greatly inhibited the up-regulation of C/EBPα/H9251. Meanwhile, PPARγ/H9253 remained down-regulated in both types of cells, suggesting that additional factors, different from Nr2f6, might be contributing to its regulation (Fig. 5B). During adipocyte differentiation, overexpression of Nr2f6 in 3T3-L1/Mock cells increased the accumulation of lipid droplets and accelerated their differentiation in comparison to nontransfected cells (Fig. 5C–5D). Visualization of culture plates and quantification of extracted Oil Red O absorbance accumulated in 3T3-L1/Mock cells confirmed that enhanced expression of Nr2f6 increased significantly adipogenesis (Fig. 5D). Excessive cell death caused by ectopic expression of Nr2f6 in Snail-transfected 3T3-L1 cells made impossible to carry out differentiation experiments in these conditions. Finally, overexpression of Nr2f6 caused a lower proliferation rate of 3T3-L1/Mock cells, in contrast with the highly proliferative rate induced by Snail1 (Fig. 5E). This lower proliferation might be associated to the increase in cell death caused by the enhanced expression of Nr2f6.

Snail Expression Induces the Synthesis of IL-17—The nuclear orphan receptor Nr2f6 is a repressor of IL-17 expression, suppressing Th17 cell functions (29). IL-17 inhibits adipogenesis downstream of C/EBPα and C/EBPβ and upstream of C/EBPγ and PPARγ (30). To determine if the effect of Nr2f6 on adipogenesis was mediated by IL-17, we checked the levels of IL-17 and other cytokines analyzing conditioned medium of Snail-expressing and mock cells using a cytokine-specific microarray. After densitometry and quantification, we observed a significant difference for IL-17 and TNFα between Snail-expressing and mock cells (Fig. 6A). To confirm these results, we quantified IL-17 by ELISA using the same cells and the results were similar to that obtained with the array (Fig. 6B). Moreover, IL-17 expression was increased in Nr2f6-silenced cells and decreased in cells ectopically expressing Nr2f6 (Fig. 6C). To study the effect of blocking IL-17 activity...
on adipogenesis, Snail1-expressing 3T3-L1 cells were treated with anti-IL17 antibody (500 ng/ml) every 2 days upon addition of the adipogenic mixture. Despite the relatively low antibody concentration, treated cells showed a significant recovery of differentiation capacity, visually and by colorimetry (Fig. 6D). Collectively, these results demonstrated a capacity of mesenchymal cells to secrete IL-17 and inhibit adipocyte differentiation upon Snail expression and the concomitant loss of Nr2f6.

**DISCUSSION**

By using a sensitive and quantitative proteomic analysis, we identified a number of transcription factors, cytokines, and growth factors deregulated by Snail. The capacity of Snail to bind and regulate the selected transcription factors was confirmed by luciferase and ChIP assays. We provide diverse evidences that Snail regulates adipocyte differentiation in mesenchymal cells through the inhibition of the nuclear orphan receptor Nr2f6, which antagonizes the expression of the pro-inflammatory cytokine IL-17 (31). Snail overexpression induced IL-17 as well as TNFα secretion in 3T3-L1 and mMSCs. We demonstrated that enhanced expression of Nr2f6 or blocking of IL-17 activity enabled the recovery of adipocyte differentiation. Collectively, our results suggest an early effect of Snail on adipogenesis mediated through Nr2f6 and IL-17 that occurs upstream of C/EBPβ and PPARγ proteins (Fig. 7).

Our proteomic data of Snail-transfected cells agree with the up-regulation of C/EBPβ induced by IL-17 and associated to early differentiation of adipogenesis (32, 33). Exogenous IL-17 inhibited 3T3-L1 adipogenesis (34) through C/EBPα, PPARγ, and Kruppel-like factors (30). However, no insights about the
provenance of this IL-17 were given or the reasons behind the presence of a Th17 cytokine in the differentiation of mesenchymal cells to adipocytes were explained. Another report suggested a direct repression of PPAR by Snail based on a luciferase assay (12). However, to the light of our results and the capacity of Snail to bind multiple promoters, it is difficult to know if PPAR inhibition by Snail is functionally relevant in 3T3-L1 cells or is another unspecific repressor capacity of Snail. In fact, C/EBP and PPAR expression levels were very low in both, mock and Snail-transfected cells. Curiously, C/EBP and C/EBPβ expression was increased in Nr2f6 transfected 3T3-L1 cells, whereas the levels of Snail were not affected. This increased expression of C/EBP and C/EBPβ would support an acceleration of the differentiation program.

IL-17 is usually classified as a proinflammatory cytokine, which is known to control bone mass (7), inhibit osteoclast formation (35), and chondrocyte differentiation (36). Here, we propose a novel capacity for Snail to induce IL-17 expression in fibroblasts or mesenchymal cells. In fact, we may speculate that previously reported inhibitory effects of Snail on osteoblast differentiation (6) were also caused by IL-17. Therefore, the action of fibroblast-derived IL-17 would be more far-reaching than that restricted to Th17 cells and might contribute to the Snail regulation of cancer microenvironment. This capacity of Snail to regulate IL-17 expression suggests a role for this molecule in different pathologies as obesity, rheumatoid arthritis, or osteoporosis. Because Snail and TGFβ form a self-stimulatory loop, either Snail or TGFβ could be interesting targets on these diseases.

Our results for Nr2f6 are relatively similar to those described for Nr2f2 (also known as COUP-TFII) in adipogenesis (37) and may suggest a cooperative interaction between both nuclear orphan receptors (Fig. 7). However, the role of Nr2f2 in adipogenesis is controversial as Xu et al. (38) described the
opposite effect for Nr2f2. In our data set, Snail showed a very weak repressor effect on Nr2f2 (mean fold-change: 0.934) (data not shown). According to the Nr2fome database (39), Nr2f6 (also known as Ear2) interacts and regulates a number of nuclear receptors, among others Nr2f2, Esr1 (Estrogen Receptor), or Angptl1. Although Nr2f6 has been much less characterized than Nr2f2, it has been described that both are functionally closely related. However, whereas Nr2f2 knockout mice are lethal, Nr2f6 are viable but present some neurological disorders (40). Nr2f2 is a central node between Nr2f6 and Trip4. These interactions will require further investigation.

Another TF regulated by Snail that showed a minor effect on adipogenesis was Trip4. Trip4, also called activating signal cointegrator 1 (Asc1), is a transcription coactivator of nuclear receptors that plays a pivotal role in the transactivation of NFκB and AP1 (44). Trip4 also regulates androgen receptor transactivation and testicular function (45, 46). Trip4 has been described to interact also with PPARγ (47). In addition, Snail1 expression caused a down-regulation of the homeobox factor Prrx1, an inducer of the epithelial-mesenchymal transition (EMT). Prrx1 causes a reversion of the EMT process in cancer epithelial cell lines, apparently without Snail participation (48).

In contrast, we observed a direct repression of Prrx1 by Snail1 in preadipocyte 3T3-L1 and mMSC cells, confirmed by luciferase and ChIP assay, although silencing of Prrx1 did not affect adipogenic differentiation. Other down-regulated protein was the steroid receptor RNA activator (Sra1), which promotes adipocyte differentiation; up-regulates the expression of PPARγ, C/EBPα, and other adipocyte genes; and increases glucose uptake and phosphorylation of Akt and FOXO1 in response to insulin (49). Here, we have noticed a clear down-regulation of Sra1 that might contribute also to the suppression of PPARγ and adipocyte differentiation. Sra1 is also a component of a large complex with Nr2f6 according to the Nr2fome.

In summary, many of the Snail-regulated TFs (Nr2f6, Trip4, or Sra1) seem to interact, directly or indirectly, with PPARγ. However, Nr2f6 repression showed the stronger capacity to control adipocyte differentiation via IL-17. At the end, IL-17 seems to be the critical mediator induced by Snail for adipocyte differentiation. These results support a link between Snail1 expression, inflammation, and adipogenesis. Snail appears to be a master regulator that plays a central role at different levels to favor the expression and/or repression of a cascade of multiple transcription factors that control adipogenic gene expression at different levels. Further work is required to precisely define the interaction network between other identified transcription factors. These results provide a...
**Snail1 Induces IL-17 Expression to Inhibit adipogenesis**

functional role for Snail in obesity that goes beyond the control of the EMT process and epithelial plasticity.
