Effect of dietary supplementation on the prognostic value of urinary and serum 8-isoprostaglandin F2α in chemically-induced mammary carcinogenesis in the rat

Barbara Bobrowska1†, Andrzej Tokarz1†, Sławomir Białek2†, Małgorzata Seweryn1†

Abstract

Background: The aim of the present study was to assess the effects of zinc or copper and polyphenolic compounds on the 8-isoprostaglandin F2α concentration in the serum and urine of rats with mammary cancer (adenocarcinoma) induced with 7,12-dimethylbenz[a]anthracene. The research focused on the kinetics of alterations in urinary 8-isoPGF2α at the early stage of carcinogenesis as well as the influence of dietary factors on the process. The impact of selected compounds on the intensity of DMBA-induced carcinogenesis was also assessed.

Result and conclusions: Administration of DMBA, a compound that induces mammary tumors in experimental animals, increased the serum and urinary 8-isoPGF2α levels in study rats. In the rat model, diet supplementation with zinc, combined with selected polyphenolic compounds (resveratrol or genistein) yielded a statistically significant decrease in the rat serum and urinary biomarker concentration with a simultaneously significant stimulation of carcinogenesis. The results indicate that there is an inverse correlation between the intensity of DMBA-induced carcinogenicity and the level of 8-isoPGF2α in urine and serum of rats.

Introduction

Breast cancer represents the most common neoplastic disease in females, accounting for up to one third of new diagnoses of women's cancer in certain region of the world. The fundamental issue in breast cancer control is prevention, which depends on detection of the determinants of the disease, in terms of initiation and promotion. It is worth mentioning that despite numerous research conducted in different areas, currently there is no one ideal, specific biomarker of the early phase of cancer development, including breast cancer. The possibility of using biomarkers of breast carcinogenesis, such as 8-isoprostaglandin F2α, and dietary factors is very promising [1,2].

F2α-isoprostanes are the isomers of F-prostaglandin, produced by cyclooxygenase-independent free radical peroxidation of arachidonic acid. The formation of 8-isoPGF2α causes damage to biomembranes and to oxidative modification of plasma lipoproteins. Carcinogenesis may be initiated by lipid peroxidation, which ultimately produces damage to proteins and DNA [3].

Another problem is the influence of dietary factor on biomarkers and the mechanisms of the disease development process. It is estimated that approximately one-third of human cancers are associated with inappropriate dietary habits and lifestyle. Therefore, dietary intake of trace elements and polyphenols becomes an important factor in controlling oxidative stress and the pathologies that ensue [4-8].

The aim of the present study was to assess the effect of zinc or copper and polyphenolic compounds (resveratrol or genistein) on the concentration of 8-isoprostaglandin F2α in the serum and urine of rats with mammary cancer (adenocarcinoma) induced with 7,12-dimethylbenz[a] anthracene. No reports have shown kinetic alterations in the urinary 8-isoPGF2α quantity excreted at the early
stage of carcinogenesis or the impact of dietary factors on the process. The impact of selected compounds on the intensity of DMBA-induced carcinogenesis was also assessed.

It is still not clear what kind of combinations and doses of trace elements and polyphenolic compounds should be given in order to achieve the most beneficial health effects in human cancer prevention or for improvement of pharmacological treatment.

Materials and methods

Laboratory animals

Female Sprague-Dawley rats were obtained from the Animal Laboratory, Department of General and Experimental Pathology, Medical University of Warsaw. The study was approved by the Ethics Committee, Medical University of Warsaw. The animals were divided into 12 groups (Table 1). Those in groups 1 to 6 (n = 60) were treated twice with 80 mg/kg of body weight DMBA (Sigma-Aldrich, St. Louis, MO, USA) in rapeseed oil (via gavage) to induce mammary cancer (adenocarcinoma); the first treatment was given at 50 days, followed by the same dose (a repeat dose of 80 mg/kg body weight) at 80 days of rat age. Rats from groups 7 to 12 (control groups) (n = 40) were accommodated under the same conditions as those from groups 1 to 6, and received the same diet, but no DMBA treatment. Tumors were evaluated histopathologically to confirm malignancy and to prove that they were adenocarcinomas (II and III degree). In DMBA-untreated groups spontaneous cancers were not observed.

All animals had a free access to water and food (standard diet: Labofeed H, Żurawia 19, 89-240 Kcyria, Poland). Table 1 shows additional different types of bioelements or polyphenolic compounds also given to the animals. The rats were fed extra supplements suspended in water, (0.4 ml daily via gavage), from 40 days until 20 weeks of age (sacrifice time by decapitation). The animals were fed only the standard diet (without supplementation) received 0.4 ml of water. The polyphenol dose levels were selected based on human average daily consumption (extrapolating on the rats’ body weight) [9,10]. The doses of bioelements were established based on the values used in the Labofeed H diet (standard diet) (77 mg Zn/kg diet; 21.3 mg Cu/kg diet) [11]. The zinc and copper content in the standard diet were determined following wet microwave sample mineralization using atomic absorption spectrophotometry (AAS). The dose levels of each agent were selected for projected drug levels.

In order to obtain rat urine samples, the animals were placed in individual metabolic cages for 24 hours. Urine was collected at 10 and 12 weeks of age, at an early, nonpalpable stage of carcinogenesis. The animals were sacrificed by decapitation at 20 weeks of age, and serum were collected. The biomaterial samples were stored at a temperature of -70°C until the test time.

The concentration of 8-isoPGF₂α in serum and urine was determined by a competitive enzyme-linked immunosorbent assay (ELISA) (8-isoprostane EIA kit, Cayman Chemical Company (Ann Arbor, MI, USA).

Determination of creatinine level

The 8-isoPGF₂α level was standardised by conversion to the creatinine level. The latter was examined in urine samples with creatinine test (Hydrex, Warsaw, Poland) based on Jaffe’s reaction (in an alkaline environment creatinine forms a colored complex with picric acid).

Superoxide dismutase (SOD) activity

Superoxide dismutase activity in serum was determined with the Superoxide Dismutase Assay kit, Cayman Chemical Company (Ann Arbor, MI). The assay kit utilizes a tetrazolium salt for detection of superoxide radicals generated by xanthine oxidase and hypoxanthine. One unit of SOD is defined as the amount of enzyme needed to exhibit 50% dismutation of the superoxide radical. The SOD assay measures all three types of SOD (Cu/Zn, Mn and FeSOD).

The animals were examined by palpation during the study to characterize the time course of tumor development. At sacrifice (at 20 weeks of rats’ age) tumors

Table 1 Composition of diets administered of different groups

| Diets                                      | DMBA + | DMBA - |
|--------------------------------------------|--------|--------|
| Standard diet +                            |        |        |
| Zinc 6.9 mg/mL (231 mg Zn/kg diet)         | +      | +      |
| Copper 1.3 mg/L (42.6 mg Cu/kg diet)       | -      | +      |
| Zinc 6.9 mg/mL (231 mg Zn/kg diet) and resveratrol 0.1 mg/mL (0.2 mg/kg bw) | -      | +      |
| Zinc 6.9 mg/mL (231 mg Zn/kg diet) and genistein 0.1 mg/mL (0.2 mg/kg bw) | -      | +      |
| Copper 1.3 mg/L (42.6 mg Cu/kg diet)       | -      | +      |

were removed, weighed and histopathological examina-
tion was performed.

The results obtained were statistically assessed using
the Kolmogorow-Smirnow test, ANOVA with POST-
HOC NIR tests (SPSS 12 programme).

Results and discussion
Mammary glands of several rat strains, mainly Spraque-
Dawley, are susceptible to transformation induced by
chemical carcinogens. One widely used active chemical
inductors of mammary carcinogenesis is 7,12-dimethyl-
benz[a]anthracene [1]. The results of this study indi-
cated that the amount of 8-isoPGF$_{2\alpha}$ in serum and
urines from rats treated with cancerogenic factor and
receiving a standard diet was higher than in the control
group receiving analogous diet but with no DMBA
treatment, however, the differences were not statistically
significant for the reason of high values of standard
deviation (Figures 1, 2 and 3). Similar trend regarding
amount of 8-isoPGF$_{2\alpha}$ in serum of rats treated with car-on tetrachloride was acquired by Kadiiska et al. [12].
Administration of DMBA resulted in an increase of
biomarkers indicating damage of DNA (8-hydroxy-2’-
deoxyguanosine), proteins (carbonyl groups of amino
acids) and lipids (8-isoPGF$_{2\alpha}$) [13]. These findings may
confirm the relationship between DMBA and stimula-
tion of the free radical processes.

It was found that zinc administration combined with
selected polyphenolic compounds (resveratrol or genis-
tein) statistically decreased the biomarker content level in
the rat serum and urine compared with the animals
receiving exclusively a standard diet (p < 0.05) (Figures 1,
2 and 3). It was demonstrated that diet supplementation
with zinc did not decrease the content level of the stu-
died biomarker in serum of DMBA-treated rats. On the
contrary, it stimulated the process ($853,576 \pm 428,232$
versus $897,979 \pm 400,809$ pg/ml), although, the response
was not statistically significant (p < 0.05). In this case,
synergistic reactions between Zn and polyphenols was
observed. Evidence shows an ability of polyphenols to scavenge free radicals, build complexes with metal ions cata-
lysing formation of free radicals, and also inhibiting
certain enzymes participating in oxidation [6-8].

Zn plays an essential role in cell membrane integrity
and is a component of more than 300 different enzymes
that function in many aspects of cellular metabolism. In
numerous systems Zn can antagonize the catalytic prop-
erties of the redox-active transition metals (Fe and Cu)
with respect to their abilities to promote formation of
hydroxyl radical (•OH) from H$_2$O$_2$ and superoxide [14].
Surprisingly, the results of our work indicated no con-
nection between superoxide dismutase activity and Zn
or Cu supplemented diets (Table 2). Therefore, the deci-
sion was made to discontinue the search for mutual cor-
relations of 8-isoPGF$_{2\alpha}$ concentration, dependent on the
diet and the enzyme activity, especially, that the rat
group receiving additional zinc exhibited a stimulated
lipid peroxidation (Table 2, Figures 1, 2 and 3). There is
no univocal evidence in the literature to confirm that
dietary zinc supplementation in applied dose exerts an

impact on the activity of superoxide dismutase. Reports seem to indicate that diets supplemented with zinc in different quantities did not cause significant changes in SOD activity, what was also confirmed by our study [15,16].

Many researchers have investigated the dietary supplementation effects on the levels of urinary isoprostane or isoprostane metabolites. Diets rich in fruit and vegetables diminish the excretion of urinary 8-isoPGF$_2\alpha$ [2]. The streptozotocin model of diabetes used in the rats

showed reduced biomarker levels following the diet supplementation with vitamin E [17]. Urinary and plasma \( \text{F}_2\)-isoprostanes were significantly decreased with alcohol-free red wine [18].

Cooper is generally considered as a pro-oxidant metal that participates in Fenon-like reactions. One of the mechanisms of procancerous Cu activity involves its ability to produce a strongly reactive hydroxyl radical responsible for oxidative damage to DNA strands and also peroxidation of cell membrane lipids [14]. As shown in our paper, the animals receiving diet supplemented with copper or copper and resveratrol had significantly higher amount of 8-isoPGF\(_{2\alpha}\) in urine compared with the animals receiving a standard or zinc supplemented diet (\(p < 0.05\)) (Figure 2, 3). This implies a pro-oxidant effect of cooper.

Another relevant issue in our study was to assess the severity of carcinogenesis expressed by tumor weight and number in particular rat groups as well as the onset of the initial tumors (Table 3). The data refer to tumors evaluated in 20th week of the animals age (decapitation time). The largest and most numerous tumors per animal were found in the group receiving zinc and resveratrol supplemented diet, which might have been due to the fact that in that group the first tumors appeared at 13 weeks of rat age, i.e. two weeks earlier than in the group fed the standard diet. Zinc compounds are considered to be chemopreventive agents chiefly due to their antioxidative properties. However, reports show that excessive Zn in the animal body may exacerbate tumorigenesis [14]. The harmful role of Zn in tumorigenesis could depend on the dose of zinc and synergism between various antioxidant used in the study. What is interesting there was an inverse correlation between the intensity of cancer development process and the level of 8-isoPGF\(_{2\alpha}\) in urine and serum of rats. A plausible explanation of this fact could be that Zn acts to improve health through a wide variety of biological mechanisms and not antioxidant activity alone. Thomson et al [19] reported a moderately significant inverse association of 8-isoPGF\(_{2\alpha}\) within plasma carotenoid levels, a protective association not seen with dietary carotenoid levels.

\(^1\) Tumor incidence is expressed as the number of tumor-bearing rats over total number of rats in the group.
Conclusions
Administration of DMBA, a compound that induces mammary cancer, increased the level of 8-isoPGF$_{2a}$ in serum and urine of tested rats. In this model, a diet supplementation with zinc combined with selected polyphenolic compounds (resveratrol or genistein) caused statistically significant decrease in concentration of the studied biomarker (8-isoPGF$_{2a}$) in rat serum and urine with simultaneous significant stimulation of carcinogenesis. Finally, the level of 8-isoPGF$_{2a}$ seen in the serum and urine in the rat model did not indicate a positive correlation with the risk of carcinogenesis, and this response, to some extent negates the value of 8-isoPGF$_{2a}$ as a potential determinant of early pathogenesis of cancer.
