(Dated: November 10, 2018)

An Ising model on the kagome lattice with super-exchange interactions is solved exactly under the presence of a nonzero external magnetic field. The model generalizes the super-exchange model introduced by Fisher in 1960 and is analyzed in light of a free-fermion model. We deduce the critical condition and present detailed analyses of its thermodynamic and magnetic properties. The system is found to exhibit a second-order transition with logarithmic singularities at criticality.

I. INTRODUCTION

The Ising model in a nonzero magnetic field is a well-known unsolved problem in statistical mechanics. In 1960, Fisher \cite{1} produced a remarkable solution of a super-exchange antiferromagnetic Ising model in the presence of a nonzero field. The Fisher model is defined on a decorated square lattice where there is an external magnetic field applied to decorating spins which interact via super-exchange interactions.

In this paper we consider similar super-exchange models on the kagome lattice. The kagome lattice has been of interest in recent years in the role it plays in the high-\(T_c\) superconductivity. It has been known that special cases of the Kagome Ising model are soluble in the presence of a magnetic field \cite{2,3}. The structure of the ferrimagnet \(\text{SrCr}_8\text{Ga}_4\text{O}_{19}\), for example, is found to consist of 2D spinel (kagome) slabs \cite{4} with magnetic spins residing at 1/3 of the lattice sites. Thus it is of interest to consider models with similar structures. Azaria and Giacomini \cite{5} have extended the Fisher model by considering the kagome lattice shown in Fig. 1(a), which reduces to the Fisher model upon setting \(K_1 = 0\). They obtained its partition function from which the phase diagram is deduced. But there has been no detailed discussion of its thermodynamic properties. Here, we consider yet another extension of the Fisher model to a kagome lattice as shown in Fig. 1(b). We show that the partition function of this model is identical to the Azaria and Giacomini solution \cite{5}, although there appears to be no direct mapping between the two models. In addition, we also present detailed analyses of the thermodynamics of the solution.

Consider an Ising model shown in Fig. 1(b) with an interaction energy

\[ -J_1\sigma_1\sigma_2 + J(\sigma_2\sigma_3 - \sigma_3\sigma_1) \]

around every triangle formed by spins \(\sigma_1, \sigma_2, \sigma_3\). Introduce reduced interactions \(K = \beta J, K_1 = \beta J_1\), where \(\beta = 1/kT\), such that \(K, K_1 > 0\) indicate ferromagnetic interactions. In addition, there is an external magnetic field \(H\) applied to 2/3 of the lattice sites denoted by solid circles. We denote the reduced field by \(L = H/kT\). As a result, the magnetic spins interact with an super-exchange interaction via intermediate non-magnetic spins. It is clear that there is no loss of generality to restrict considerations to \(H, J \geq 0, \quad L, K \geq 0\).

For \(K_1 = 0\) the model reduces to the Fisher model for the square lattice. For \(K_1 \neq 0\) the present model is more general and differs from the Fisher model in a fundamental way as described in Sec. 2 below.

Our main result is a closed-form solution of the partition function and detailed analyses of thermodynamic and magnetic properties. In Sec. 2 we deduce the solution using a combination of star-triangle and decimation transformations. The phase diagram is analyzed in Sec. 3. In Secs. 4 - 6 the internal energy, specific heat, magnetization, and susceptibility are analyzed using a free-fermion model formulation \cite{6}.

II. THE PARTITION FUNCTION

Denote the partition function of the kagome Ising lattice in Fig. 1(b) by \(Z_{\text{KGO}}(K, K_1, L)\). Our main result is an equivalence of \(Z_{\text{KGO}}(K, K_1, L)\) to the partition function of an honeycomb Ising model in zero field, a result which renders the model soluble.

This equivalence is established by effecting a sequence of spin transformations. First, we carry out a star-triangle transformation for every triangular face as shown in the first line in Fig. 2. This converts the kagome lattice to a decorated honeycomb lattice. Next the decorating spins are decimated as shown in the second and third lines in Fig. 2, and the lattice is reduced to that of an honeycomb. The crux of matter is that the external fields \(L_1\) and \(-L_1\) induced in the second step cancel out at the end. As a result, the final honeycomb lattice has no external field and is soluble. It has reduced interactions \(R, R\) and \(R_1\) in the three principal directions.

The transformations shown in Fig. 2 are standard \cite{6}. For the transformation in the first line in Fig. 2, we...
FIG. 1: (a) and (b) are two soluble Kagome lattice Ising models in a magnetic field. Solid circles denote magnetic spins and open circles non-magnetic spins. Both models are mapped to a honeycomb Ising lattice without a field shown in (c). $F^N$ is an overall factor.

For the transformation in the second line in Fig. 2, we have

$$2 \cosh 2\Gamma_1 = F_2 e^{R_1}$$
$$2 = F_2 e^{-R_1}$$

from which we obtain

$$F_2^2 = 4 \cosh 2\Gamma_1$$
$$e^{2R_1} = \cosh 2\Gamma_1 = \frac{e^{-4\Gamma_1} \cosh 4K - 1}{e^{-4\Gamma_1} - 1}$$

where the last step is obtained after making use of (11). Equation (10) shows that $R_1$ is real, and $R_1 > 0$ in regime I and $R_1 < 0$ in regime II.

For the transformation in the third line in Fig. 2, we have

$$2 \cosh(L + 2\Gamma) = F_3 e^{-R_1}$$
$$2 \cosh(L - 2\Gamma) = F_3 e^{-R_1}$$
$$2 \cosh L = F_3 e^{R_1}$$

from which we obtain

$$e^{4R} = \frac{\cosh(L + 2\Gamma) \cosh(L - 2\Gamma)}{\cosh^2 L} = 1 + \frac{\sinh^2 2\Gamma}{\cosh^2 L}$$
$$e^{4L_1} = \frac{\cosh(L + 2\Gamma)}{\cosh(L - 2\Gamma)}$$
$$F_3^4 = 16 \cosh^2 L \cosh(L + 2\Gamma) \cosh(L - 2\Gamma).$$

Thus, $R$ is always real, and we have

$$R < 0, R_1 > 0, \quad \Gamma, \Gamma_1, L_1 = \text{real}, \quad \text{regime I}$$
$$R > 0, R_1 < 0, \quad \Gamma, \Gamma_1, L_1 = \text{imaginary}, \quad \text{regime II}$$

This says that $R$ and $R_1$ have opposite signs. In the solution obtained by Azaria and Giacomini [11], the final equivalent honeycomb Ising model is identical with ours.
except the replacement of $R$ by $-R$. However, as we shall see below, the negations of $R$ and/or $R_1$ do not affect the solution. Therefore, the two solutions are identical.

Combining (3), (9), (10), and after some reduction, we obtain

$$F^4 = F_1^4 F_2^4 F_3^2$$

$$= \frac{4 \cosh^2 L (e^{4K_1} \sinh^2 L + \cosh^2 2K)}{\cosh^2 R_1}. \quad (18)$$

Now the field $L_1$ at the decorating sites is canceled and we arrive at the final equivalence

$$Z_{KG}(K, K_1, L) = F^N Z_{HC}[R(L), R_1] \quad (19)$$

where $Z_{HC}[R(L), R_1]$ is the partition function of the honeycomb Ising lattice. Here, $N$ is the number of triangular faces (or the number of magnetic spins) of the kagome lattice, which is also the number of honeycomb lattice sites. Note that the $L$ dependence is only in $R$.

The transformation (19) reduces to that of Fisher’s for the square lattice after setting $K_1 = 0$ ($R_1 = \infty$). But our model differs from the Fisher model in a crucial aspect: The Fisher model results in a square lattice whose sites are the decorating sites of the original lattice, in the present model all the sites of the original kagome lattice disappear at the end. Thus the ordering of the honeycomb lattice bears no direct relationship to that of the kagome lattice. In addition, while there is no frustrated plaquettes in the Fisher model, in the $K_1 > 0$ model all triangular faces are frustrated.

Introduce the per magnetic spin free energy

$$f_{KG}(K, K_1, L) = \lim_{N \to \infty} N^{-1} \ln Z_{KG}(K, K_1, L)$$

and the per-site honeycomb lattice free energy

$$f_{HC}(R, R_1) = \lim_{N \to \infty} N^{-1} \ln Z_{HC}(R, R_1). \quad (20)$$

Taking the $N \to \infty$ limit of (19) and making use of the explicit expression of $f_{HC}$ given in (8), (9), we obtain for the kagome Ising model,

$$f_{KG}(K, K_1, L) = \ln F + f_{HC}(R, R_1)$$

$$= \ln F + \frac{3}{4} \ln 2$$

$$+ \frac{1}{16\pi^2} \int_0^{2\pi} d\theta d\phi \ln \Xi(\theta, \phi) \quad (21)$$

where

$$\Xi(\theta, \phi) = \cosh 2R_1 \cosh 2R \sinh^2 2R \cos(\theta + \phi)$$

$$- \sinh 2R_1 \sin 2R (\cos \theta + \cos \phi). \quad (22)$$

Note that the negation of either $R$ or $R_1$ corresponds to changing $\theta \to \pi - \theta, \phi \to \pi - \phi$ in (22) which does not change the free energy $f_{KG}$.

As a check, we recover the Fisher solution upon setting $K_1 = 0$ or $R_1 \to \infty$:

$$f_{KG}(K, 0, L) = \frac{3}{2} \ln 2 + \frac{1}{4} \ln[\cosh^2 L (\sinh^2 L + \cosh^2 2K)]$$

$$+ \frac{1}{16\pi^2} \int_0^{2\pi} d\theta d\phi \ln \left[ \cosh^2 2R - \sinh 2R (\cos \theta + \cos \phi) \right] \quad (23)$$

with $e^{-4R} = (\sinh^2 L + \cosh^2 2K)/\cosh^2 L$.

The internal energy and magnetization per magnetic spin are, respectively,

$$U(K, K_1, L) = -\frac{\partial}{\partial \beta} f_{KG}(K, K_1, L), \quad (24)$$

$$M(K, K_1, L) = \frac{\partial}{\partial L} f_{KG}(K, K_1, L). \quad (25)$$

The specific heat and susceptibility are further computed as

$$C_{HI}(K, K_1, L) = \frac{\partial}{\partial T} U(K, K_1, L), \quad (26)$$

$$\chi(K, K_1, L) = \frac{\partial}{\partial H} M(K, K_1, L). \quad (27)$$

### III. THE PHASE DIAGRAM

The integral in the free energy $f_{KG}$ is precisely of the form of that of the free-fermion model discussed by Fan and Wu [10] for which the critical condition is (for $RR_1 < 0$)

$$\Xi(\pi, \pi) = 0. \quad (28)$$

Alternately, the critical point for an anisotropic honeycomb Ising lattice has been given in [1] as $C_iC_2C_3 + 1 = S_iS_2 + S_2S_3 + S_3S_1$ where $C_i = \cosh 2R_1, S_i = \sinh |2R_i|, i = 1, 2, 3$. It is also given by the expression $\omega_1 = \omega_2 + \omega_3 + \omega_4$ [1] where the $\omega$’s are given in the next section. Using any of these expressions, we obtain the critical condition

$$\sinh[2R(L)] = -\coth R_1. \quad (29)$$

Explicitly, (29) reads

$$\cosh^2 L = \frac{1}{2} \left[ \sqrt{1 + \tanh^2 R_1 - 1} \right]$$

$$\times \left( e^{-4K_1} \cosh^2 2K - 1 \right), \quad T = T_c (H\beta)$$

which can be realized only in regime I and $K_1 \leq K$, or $\gamma \leq 1$ (see below). Note that for $K_1 = 0$ (21) reduces to the Fisher expression

$$\cosh L = \sqrt{(\sqrt{2} - 1)/2} \sin 2K. \quad (31)$$
It can be verified that we have
\[| \sinh 2R(L) | < | \coth R_1 |, \quad T > T_c(H). \] (32)

Introduce parameters
\[
\alpha = \frac{L}{2K} = \frac{H}{2J} > 0 \\
\gamma = J_1/J = K_1/K
\] (33)
such that \( \gamma > 0 \) indicates \( J_1 \) is ferromagnetic, and consider the phase diagram \( \text{(30)} \) in the \( \{ \alpha, 1/K \} \) plane, where \( 1/K \) is the temperature. The phase diagram is plotted in Fig. 3 for different fixed values of \( \gamma \).

\[ \text{FIG. 3: Phase boundary in the } \alpha-T \text{ plane for fixed values of } \gamma. \]

At low temperatures the phase boundary behaves as
\[ \alpha = 1 - \gamma - \frac{1}{4K} \ln 2(\sqrt{2} + 1) \] (34)
with an initial slope independent of \( \gamma \). Solving \( \text{(30)} \) for \( \gamma \) at \( H = 0 \), we obtain
\[ \gamma = \frac{1}{2K_c} \left[ 2 \ln(\sinh 2K_c) - \ln(2 \cosh 2K_c) \right]. \] (35)
We see that \( T_c(0) \) decreases with \( \gamma \), reaching \( T_c(0) = 0 \) at \( \gamma = 1 \). It follows that there is no transition when
\[ \gamma \geq 1, \quad \text{or } K_1 \geq K \] (36)
as aforementioned. This can be understood physically since, in the limit of \( \gamma \rightarrow \infty \), the non-magnetic spins can assume values \( \pm 1 \) randomly and there is no ordered state.

For small \( H \) \( \text{(30)} \) is expanded as
\[ T_c(H) = T_c(0) - CH^2, \] (37)
where \( C \) is a constant given by
\[ C^{-1} = kJ \left[ \frac{32(16 - 24t^4 + t^8)}{t^6(4 + 4t^2 - t^4)} + \frac{16(-4\gamma + 4t + t^5)}{16 - t^8} \right], \]
with \( t = \tanh 2J/kT_c(0) \).

To determine the nature of regimes in the phase diagram, we consider the ground state. At zero temperature the kagome lattice can assume two ordered states:

(i) All magnetic spins aligned in the same direction with the total energy
\[ U_1 = -N(2\alpha + \gamma)J \] (38)
independent of the spin directions of the non-magnetic spins. Since the \( N/2 \) non-magnetic spins can point in any direction, the entropy of this ground state is \( \frac{1}{2}NK \ln 2 \).

(ii) The magnetic spins connected by interactions \( -J \) assume the value +1 (or −1) and those connected by interactions \( +J \) assume the value −1 (or +1), while all non-magnetic spins are fixed at +1 (or −1). This forms a super-exchange antiferromagnetic state with the energy
\[ U_2 = -N(2 - \gamma)J, \] (39)
and the ground state is two-fold degenerate with zero entropy in the thermodynamic limit.

Comparing \( U_1 \) with \( U_2 \), for \( \alpha > 1 - \gamma \) which is the regime to the “exterior” of the critical curve \( \text{(30)} \), we have \( U_1 < U_2 \) indicating the system is paramagnetic. For \( \alpha < 1 - \gamma \) which is the regime enclosed by the critical curve, we have \( U_1 > U_2 \) and the system assumes a super-exchange antiferromagnetic ordering.

\section*{IV. THERMODYNAMIC PROPERTIES}

To analyze thermodynamic and magnetic properties given by \( \text{(24) - (27)} \), we make use of results of \( \text{(16)} \). Writing \( \text{(22)} \) in the form of Eq. (16) of \( \text{(4)} \), we have
\[ \Xi(\theta, \phi) = 2a + 2b \cos \theta + 2c \cos \phi + 2d \cos(\theta + \phi), \] (40)
with
\[ a = \cosh 2R_1 \cos^2 2R + 1 = \frac{1}{2}(\omega_1^2 + \omega_2^2 + \omega_3^2 + \omega_4^2), \]
\[ b = -\sinh 2R_1 \sinh 2R = \omega_1 \omega_3 - \omega_2 \omega_4, \]
\[ c = -\sinh 2R_1 \sinh 2R = \omega_1 \omega_4 - \omega_2 \omega_3, \]
\[ d = -\sinh^2 2R = \omega_3^2 \omega_4 - \omega_1 \omega_2, \] (41)
or
\[ \omega_1 = \cosh(2R - R_1), \]
\[ \omega_2 = \cosh(2R + R_1), \]
\[ \omega_3 = \omega_4 = \cosh R_1. \] (42)

Using \( \text{(12)} \) we compute the parameters \( \{ x, y, z \} \) introduced in \( \text{(11)} \) as
\[ x = \omega_1 \omega_4 - \omega_2 \omega_3 = -\sinh 2R \sinh 2R_1, \]
\[ y = \frac{1}{2}(\omega_1^2 - \omega_2^2 - \omega_3^2 + \omega_4^2) = -\frac{1}{2} \sinh 4R \sinh 2R_1, \]
\[ z = \omega_1 \omega_4 + \omega_2 \omega_3 = 2 \cosh 2R \cos^2 R_1. \] (43)
Here we have reversed the sign of $x$ from 29 to make $x > 0$. This is permitted since only $x^2$ appears in the ensuing discussions. The critical condition 30 is equivalent to $y = z$ and we have the regimes

\begin{align*}
y > z > x > 0, & \quad T < T_c(H) \\
z > y > x > 0, & \quad T > T_c(H).
\end{align*}

(44)

It was established in 21 that derivatives of the free energy are best computed by first carrying out one-fold integration. Adopting notations in 21, we obtain after differentiating 21 the expression

\[ [f_{KG}(K_1, L)]' = C_0 + C_1I_1 + C_2I_2 + C_3I_3, \]

(45)

where the prime denotes the derivative with respect to some variable such as $T$ and $H$,

\begin{align*}
C_0 &= \frac{F'}{F} + \frac{b' d'}{4b}, \quad |R_1| > |R| \quad (b^2 > d^2), \\
 &= \frac{F'}{F} + \frac{d'}{4d}, \quad |R_1| < |R| \quad (d^2 > b^2), \\
C_1 &= a' \left( \frac{b' d'}{4d} + \frac{b^2 - d^2}{b - d} \right), \\
C_2 &= \frac{b'}{2} \left( \frac{b'}{b - d} \right), \\
C_3 &= -\frac{1}{2} \left( \frac{b'}{b - d} \right)^2 \frac{b^2 - d^2}{2d} \left( \frac{2ad}{b^2 + d^2} - 1 \right),
\end{align*}

(46)

and

\begin{align*}
I_1 &= \frac{1}{8\pi} \int_0^{2\pi} d\phi [Q(\phi)]^{-1/2}, \\
I_2 &= \frac{1}{8\pi} \int_0^{2\pi} d\phi \cos \phi [Q(\phi)]^{-1/2}, \\
I_3 &= \frac{1}{8\pi} \int_0^{2\pi} d\phi (1 + \omega \cos \phi)^{-1} [Q(\phi)]^{-1/2}
\end{align*}

(47)

with

\begin{align*}
\omega &= -\frac{2bd}{(b^2 + d^2)} > 0, \\
Q(\phi) &= \frac{x^2(\cos \phi - yz/x^2)}{2} + \frac{(x^2 - y^2)(z^2 - x^2)/x^2}. 
\end{align*}

(48)

Carrying out the integrations in 47, we obtain explicitly for $T \geq T_c(H)$ ($z > y > x > 0$) the result 10

\begin{align*}
I_1 &= \frac{1}{2\pi \sqrt{z^2 - x^2}} K(k), \\
I_2 &= \frac{1}{2\pi yz \sqrt{z^2 - x^2}} \left[ z^2 K(k) + (y^2 - z^2) \Pi(r, k) \right], \\
I_3 &= \frac{1}{2\pi (y + \omega z) \sqrt{z^2 - x^2}} \left[ yK(k) + \frac{\omega (z^2 - y^2)}{z + \omega y} \Pi(s, k) \right]
\end{align*}

(49)

where

\begin{align*}
k^2 &= \frac{(y^2 - x^2)/(z^2 - x^2)}, \\
r &= \frac{y^2}{z^2}, \\
s &= \frac{(\omega z + y)^2/(z + \omega y)^2}
\end{align*}

(50)

and $K$ and $\Pi$ are elliptical integrals of the first and third kinds, respectively,

\begin{align*}
K(k) &= \int_0^{\pi/2} \frac{d\alpha}{\sqrt{1 - k^2 \sin^2 \alpha}} \\
\Pi(r, k) &= \int_0^{\pi/2} \frac{d\alpha}{(1 - r \sin^2 \alpha) \sqrt{1 - k^2 \sin^2 \alpha}}.
\end{align*}

(51)

For $T \leq T_c(H)$ ($y > z > x > 0$) we obtain the same result with $y$ and $z$ interchanged.

The apparent non-analyticity of $C_0$ at $|R_1| = |R|$ as indicated in 10 is spurious. It can be shown that the combination of $C_0 + C_3I_2$ is always analytic.

At the transition temperature $y = z$ (or $k = 1, r = 1$) both $K$ and $\Pi$ diverge as $\ln |T - T_c(H)|$. Applying 10 to the internal energy 21 where the derivatives are with respect to $T$, we obtain

\[ U(H) = U_c(H) + \text{const} |T - T_c(H)| \ln |T - T_c(H)|, \]

\[ T \rightarrow T_c(H). \]

(52)

A further derivative of $U(H)$ as given by 21 gives the specific heat $C_H$. Thus, the energy is continuous at $T_c(H)$ while the specific heat diverges logarithmically. These findings, which are the same as those found in the Fisher model, indicate the occurrence of a second order transition along the phase boundary in Fig. 3. We plot $U(H)$ and $C_H$ respectively in Figs. 4 and 5. For completeness, we derive the explicit expression for $U_c(H)$ in the next section.

In the case of zero magnetic field $H = \alpha = 0$ and $\gamma = -1$, the internal energy assumes a simple expression given by

\[ U(0)/J = -1 + (1 + \tanh 2K) \left\{ 1 - \frac{1}{2} \tanh R \right\} \left[ 1 + 2(\cosh^2 2R - 3 \cosh 2R - 2)I_1 \right] \coth 2R \]

(53)

with $e^{-2R} = e^{2R_1} = (e^{4K} + 1)/2$.

V. DERIVATION OF $U_c(H)$

Define an auxiliary variable

\[ \varphi_\alpha(k) = \sin^{-1} \sqrt{\frac{1 - \alpha}{1 - k^2}} > 0 \]
where $\Lambda_0$ is Heuman’s Lambda function

$$\Lambda_0(\varphi, k) = \frac{2}{\pi} \left[ K(k)E(\varphi, k') - [K(k) - E(k)]F(\varphi, k') \right]$$

with $k' = \sqrt{1 - k^2}$ and

$$E(\varphi, k) = \int_0^\varphi (1 - k^2 \sin^2 \theta)^{1/2} d\theta$$

$$F(\varphi, k) = \int_0^\varphi (1 - k^2 \sin^2 \theta)^{-1/2} d\theta. \tag{56}$$

Particularly,

$$\Lambda_0(\varphi, 1) = \frac{2}{\pi} \varphi. \tag{57}$$

At the critical point $k \to 1$ or $y \to z$, we have

$$(z^2 - y^2)\Pi(r, k) = (z^2 - y^2)K(k)$$

$$+ \frac{\pi z^2 (z^2 - x^2)^{1/2}}{2x} \left( 1 - \frac{2}{\pi} \varphi_r \right), \tag{58}$$

$$(z^2 - y^2)\Pi(s, k) = (z^2 - y^2)K(k)$$

$$+ \frac{\pi (1 + \omega)z^2 (z^2 - x^2)^{1/2}}{2\sqrt{(1 - \omega)(1 + \omega)\omega y^2}} \left( 1 - \frac{2}{\pi} \varphi_s \right). \tag{59}$$

and

$$I_2 = I_1 - \frac{1}{4x} \left( 1 - \frac{2}{\pi} \varphi_r \right), \tag{60}$$

$$I_3 = \frac{1}{1 + \omega} \left[ I_1$$

$$+ \frac{\omega}{4\sqrt{(1 - \omega)(1 + \omega)\omega y^2}} \left( 1 - \frac{2}{\pi} \varphi_s \right) \right].$$

Let

$$q = \sinh^2 R \gtrsim \frac{1}{2}, \quad |R_1| \gtrsim |R|.$$  

Then, at the critical temperature $T_c(H)$

$$\omega = \frac{4q}{1 + 4q^2}, \quad x = 2(1 + q),$$

$$y^2 = z^2 = 4(1 + q^2)(1 + 2q)/q, \tag{54}$$

$$\varphi_r = \sin^{-1} \sqrt{\frac{1 + q}{1 + 2q}},$$

$$\varphi_s = \sin^{-1} \left[ \frac{2q}{2q + 1} \sqrt{\frac{1 + q}{1 + 2q}} \right],$$

$$I_2 = I_1 - \frac{1}{8(1 + q)} \left( 1 - \frac{2}{\pi} \varphi_r \right), \tag{55}$$

$$I_3 = \frac{1 + 4q^2}{(1 + 2q)^2} I_1$$

$$+ \frac{q}{2(1 + q)(1 - 2q)(2q + 3)} \left( 1 - \frac{2}{\pi} \varphi_s \right). \tag{61}$$
and

\[ C_1 = \frac{-(q+1)(4q^2 + 8q - 3)}{2q} \times \left( \coth 2R_1 \frac{\partial R_1}{\partial K} - \coth 2R \frac{\partial R}{\partial K} \right), \]

\[ C_2 = -2(1+q) \left( \coth 2R_1 \frac{\partial R_1}{\partial K} - \coth 2R \frac{\partial R}{\partial K} \right), \]

\[ C_3 = \frac{(q+1)(2q - 1)(2q + 3)(2q + 1)}{2q(4q^2 + 1)} \times \left( \coth 2R_1 \frac{\partial R_1}{\partial K} - \coth 2R \frac{\partial R}{\partial K} \right), \]

where

\[ \partial R_1 = \frac{2(e^{-4\gamma K_c} \sinh 4K_c - \gamma)}{e^{-4\gamma K_c} \cosh 4K_c - 1} \frac{2\gamma}{e^{-4\gamma K_c} - 1}, \]

\[ \partial R = \frac{e^{-4\gamma K_c} (\sinh 4K_c - 2\gamma \cosh^2 2K_c) + \alpha \sinh 4\alpha K_c}{2(\sinh^2 2\alpha K_c + e^{-4\gamma K_c} \cosh^2 2K_c - 1)} + \alpha \tanh 2\alpha K_c. \]

With respect to \( H \) we take the derivative in (45) and obtain after some algebra the following expression for the energy at the critical temperature:

\[ U_c(H)/J = -\gamma - 2\alpha \tanh 2\alpha K_c - \frac{1}{2} \alpha \frac{\partial R_1}{\partial K} \times \left( \coth 2R_1 \frac{\partial R_1}{\partial K} - \coth 2R \frac{\partial R}{\partial K} \right), \]

\[ q > \frac{1}{2}. \]

In the limit of \( \gamma \to 0 \) for which \( R_1 \to \infty, \varphi_r = \varphi_s = \pi/4 \), we obtain

\[ U_c(H)/J \bigg|_{\gamma=0} = -(2 - \sqrt{2})\alpha \tanh 2\alpha K_c - \frac{1}{2} \sinh 4K_c + \frac{\alpha \sinh 4\alpha K_c}{2 - \sqrt{2} \sinh^2 2\alpha K_c + \cosh^2 2K_c} \]

which is the Fisher result \[ [1]. \] Particularly, for \( H = 0 \), \[ [68] \] gives the value \(-2\sqrt{1 + \sqrt{2}}\).

**VI. MAGNETIC PROPERTIES**

For magnetic properties we take the derivative in (45) with respect to \( H \) and obtain

\[ M(H) = M_c(H) + \text{const} |T - T_c(H)| \ln |T - T_c(H)|, \]

\[ T \to T_c(H) \]

where \( M_c(H) \) is the magnetization at the critical temperature \( T_c(H) \) given by

\[ M_c(H) = \frac{1}{2} \left[ 1 - \frac{1}{\pi} (\varphi_r \pm \varphi_s) \right] (1 + e^{4R}) \tanh 2\alpha K_c, \]

\[ q \leq \frac{1}{2}. \]

The magnetization \( M \) is plotted in Figs. 6 and 7 versus \( T \) and \( H \), respectively, for \( \gamma = -1 \). To analyze \( M(H) \equiv M(\gamma, \alpha, 1/K) \) at low temperatures, we note that

\[ M(\gamma, \alpha, 0) = 0, \quad \alpha < 1 - \gamma \]

\[ = 2, \quad \alpha > 1 - \gamma . \]

The value of \( M(\gamma, \alpha, 0) \) at \( \alpha = 1 - \gamma \) depends on how the zero temperature \( T = 0 \) is approached. To see what happens we write

\[ \alpha(K, \xi) \equiv 1 - \gamma - \frac{\xi}{4K} \ln 2(\sqrt{2} + 1) \]

where \( \xi \) is a parameter controlling the approach to \( T = 0 \). Particularly, the critical curve \[ [14] \] is indicated by \( \xi = 1 \). Along \[ [19] \] and \( K \to \infty \), one has \( R_1 \simeq 2K \to \infty \), tanh \( L \to 1 \), and

\[ e^{-4R} = 1 + [2(\sqrt{2} + 1)]^\xi, \quad K \to \infty. \]
After some algebraic manipulation, we find
\[
m(\xi) = \lim_{K \to \infty} M\left(\gamma, \alpha(K, \xi), 1/K\right) = \left(e^{4R} + 1\right)\left[\frac{1}{2} + \frac{\epsilon}{\pi}(1-k)K(k)\right]
\]
with \( k = \sinh^{2\pi} 2R \). Here \( \epsilon = 1 \) for \( \xi \leq 1 \) while \( \epsilon = -1 \) for \( \xi > 1 \). We have
\[
m(\xi) = \begin{cases} 
0 & \xi = \infty \\
2 - \sqrt{2} & \xi = 1 \\
3 + \frac{21}{16\pi}K(1/8) \approx 1.408836 & \xi = 0 \\
2 & \xi = -\infty 
\end{cases}
\]

The susceptibility \( \chi(\gamma, \alpha, K^{-1}) \), which is the further derivative of \( \chi(0, K^{-1}) \) with respect to \( H \), diverges logarithmically at \( T_c(H) \) for \( H \neq 0 \). The susceptibility \( \chi \) is plotted in Fig. 8 versus temperature \( T \) for \( \gamma = -1 \) and \( \alpha = 0, 1/2 \). The zero-field susceptibility \( \chi(\gamma, 0, K^{-1}) \) is continuous. For example one has for \( \gamma = -1 \),
\[
\chi(-1, 0, K^{-1}) = 2K - \frac{K}{2}(1-e^{4R})\left\{2 - \frac{3}{2} \coth 2R + \coth 2R\left[2 \cosh 2R(3 - \sinh^2 2R) + 6\right]I_1 + \sinh 4RI_2\right\}
\]
where \( e^{-2R} = (e^{4K} + 1)/2 \). The expression (72) bears no direct relation with the critical energy \( E_0 \) as found to exist in the case of \( \gamma = 0 \) \[1\]. By direct differentiation of (67) and making use of (37), we obtain the critical susceptibility
\[
\chi(\gamma, 0, K_c^{-1}) = \frac{1}{2}K_c\left[1 - \frac{1}{\pi}(\varphi_+ \pm \varphi_-)\right] \\
\times (1 + e^{4\gamma K_c \cosh^{-2} 2K_c})
\]

Acknowledgment

We thank R. Shrock for his interest and a critical reading of the manuscript. Work has been supported in part by NSF Grants PHY-0098801 (WTL) and DMR-9980440 (FYW).
