Research article

Keywords: Follistatin-like protein-1, 3-methyladenine, autophagy, Chronic obstructive pulmonary disease

DOI: https://doi.org/10.21203/rs.3.rs-26708/v1
Abstract

Background

Cigarette smoke (CS) is a major risk factor for COPD. Follistatin-like protein 1 (FSTL1), a critical factor during embryogenesis particularly in respiratory lung development, is a novel mediator related to inflammation and tissue remodeling. We tried to investigate the role of FSTL1 in CS-induced autophagy dysregulation, airway inflammation and remodeling.

Methods

Serum and lung specimens were obtained from COPD patients and controls. Adult female wild-type (WT) mice, FSTL1+/− mice and FSTL1flox/+ mice were exposed to room air or chronic CS. Additionally, 3-methyladenine (3-MA), an inhibitor of autophagy, were applied in CS exposed WT mice. The lung tissue and serum from patients and murine models were tested for FSTL1 and autophagy associated protein expression by ELISA, western blotting and immunohistochemical. Autophagosome were observed by Electron Microscope Technology (EMT). LTB4, IL-8 and TNF-α in bronchoalveolar lavage fluid of mice were examined by ELISA. Airway remodeling and lung function were also assessed.

Results

Both FSTL1 and autophagy biomarkers increased in COPD patients and CS exposed WT mice. Autophagy activation was upregulated in CS exposed mice accompanied by airway remodeling and airway inflammation. FSTL1+/− mice showed a lower level of CS-induced autophagy compared with control mice. FSTL1+/− mice can also resist CS-induced inflammatory response, airway remodeling and impaired lung function. CS exposed WT mice with 3-MA pretreatment have a similar manifestation with CS exposed FSTL1+/− mice.

Conclusions

FSTL1 promotes CS-induced COPD by modulating autophagy, therefore targeting FSTL1 and autophagy may shed light on treating cigarette smoke induced COPD.

Background

Chronic obstructive pulmonary disease (COPD), one of the life-threatening respiratory system disorders, is projected to become the third most common cause of death worldwide by 2030. The most recent prevalence of COPD in China is 13.7% in people aged 40 years or older. COPD is characterized by a sustained airflow limitation and emphysema associated with airway remodeling and inflammation.
Complicated innate factors (e.g. host factors) and extrinsic factors (e.g. cigarette smoking) contribute to COPD, and cigarette smoke exposure still represents the most important risk factor. Most studies show that cigarette smoke is the major cause of pathogenesis and progression of COPD, which results in tremendous intractable inflammation and oxidative burden. However, the underlying mechanisms of COPD induced by cigarette smoke are complex and not fully understood. So far, there are no accurate therapies that can effectively retard or reverse disease progression.

Autophagy is a process of self-cannibalization of cellular components and a powerful promoter of metabolic homeostasis, which was activated by oxidative stress or the accumulation of damaged proteins or organelles. The elongation and maturation of autophagosomes require two ubiquitin-like conjugation system: the microtubule-associated protein 3 light chain (lc3-atg8) and Atg5-Atg12-Atg16L conjugation systems. Numerous studies report that autophagy plays an essential role either pathogenic or therapeutic in disease progression, especially in the inflammatory response in chronic respiratory disease. Previous studies indicate that CS induces autophagy activation by inhibiting mTOR and causes exacerbated lung damage. Activation of autophagy has been considered detrimental in the airway epithelium in response to CS. More detailed investigations are needed to explore the aberrant activation of autophagy in COPD pathogenesis.

Follistatin-like protein1 (FSTL1), also known as follistatin-related protein (FRP) or transforming growth factor-1β stimulated clone 36 (TSC-36), is a secreted protein that involved in respiratory development and regulation of immunologic process. FSTL1 is a novel inflammatory mediator and plays a vital role in the regulation of inflammatory cells, which is the main characteristic of COPD. Research found that FSTL1 was elevated in serum of COPD patients combined with pulmonary hypertension. We have previously shown that FSTL1 plays a role in autophagy, and may contribute to epithelial mesenchymal transition (EMT) and airway remodeling in asthmatics, but the role of FSTL1 in COPD has not been elucidated. Therefore, whether there exists an inner connection among FSTL1, autophagy and COPD needs further investigation.

**Methods**

**Patients**

Serum of COPD patients (n = 25) was taken from COPD patients who visited Qilu Hospital of Shandong University. Serum of control group (n = 28) was taken from subjects without any respiratory condition who visited our hospital. And lung specimens of COPD patients (n = 7) were obtained from patients who underwent pneumoresection for suspected or confirmed lung cancer. Control biopsy specimens (n = 6) with no history of COPD were obtained from Qilu Hospital Cadaver Donating Center. COPD was diagnosed according to the Global Initiative for COPD. The study was approved by the Ethics Committee of Qilu Hospital of Shandong University, and written informed consent was obtained. Subject information was shown in Table 1.
Table 1 Clinic characteristics of control subjects and COPD patients

|                  | CON          | COPD         |
|------------------|--------------|--------------|
| **Sex (M/F)**    | 15/13        | 15/10        |
| **Age**          | 52.214±11.764| 53.800±9.849 |
| **FEV1/FVC**     | 84.498±8.501 | 53.418±9.296 |
| **FEV1%,pre**    | 92.015±8.250 | 62.833±9.690 |

**Mice**

Age, weight, and sex matched (8-week-old, 20 ± 3 g, female) C57BL/6 mice (5–6 each group) were obtained from the Animal Experiment Center of Shandong University (Shandong, China). Mice were maintained in a pathogen-free environment at room temperature (24°C) and controlled day/night cycles with free access to water and standard laboratory chow. C57BL/6 mice were purchased from the Experimental Animal Center of Shandong University (Jinan, China). FSTL1^{ox/+} mice were a generous gift given by Xiang Gao (Nanjing University, Nanjing, China) and Xu Zhang (Institute of Neuroscience, Shanghai Institute for Biological Sciences, Chinese Academy of Sciences, Shanghai, China). The experimental procedures were approved by the Ethics Committee of Qilu Hospital of Shandong University, China.

**Cigarette smoking and 3-methyladenine challenge**

C57BL/6 mice were randomly divided into 3 separate groups: air exposed group, CS exposed group, and CS exposed group with 3-methyladenine intervention. Mice allocated to CS group were exposed to four commercially filtered cigarettes (10 mg of tar, 1.0 mg of nicotine content, 12 mg of carbon monoxide; Hademen® Filter tip cigarette) twice/day, 5 days/week for 12 weeks using a sealed chamber connected to cigarette smoke. Control mice were exposed in room air under the same conditions. 3-methyladenine intervention was administered by intratracheal injection with 3-MA (20 mg/kg/day, Sigma, USA) for 12 weeks.

**FSTL1^{+/-} mice**

FSTL1^{+/-} mice were generated as reported previously. FSTL1^{flox/+} mice and FSTL1^{+/-} mice were randomly divided to four groups (5–6 each group) and were exposed to cigarette smoking or room air for 12 weeks, as mentioned above.

**Mouse BALF collection**

24 h after the last challenge, mice were anesthetized intraperitoneally with pentobarbital sodium (1.0%, 60 mg/kg) and euthanized by decapitation. Left lungs were lavaged three times with 1 ml of ice-cold phosphatebuffered saline (PBS) via tracheal catheter to collect BALF. After centrifugation of BALF cells, the supernatant was obtained and stored at 80°C for subsequent experiments.

**Enzyme-linked immunosorbent assay**
In order to detect the level of FSTL1, IL-8, TNF-α and LTB4, we tested serum of patients and BALF of mice using enzyme-linked immunosorbent assay (ELISA) kit (CUSABIO, MD, USA) following the manufacturer's instruction. Optical densities were measured at 450 nm and the standard curve was drawn by software to calculate the concentration.

**Western blotting**

Lung tissue samples, washed with 0.01 M PBS, were lysed in ice-cold RIPA buffer containing sodium phosphate (20 mM, pH 7.4), NaCl (150 mM), 1% NP-40, 0.1% SDS, and 0.5% deoxycholic acid with sodium orthovanadate (1 mM) and protease inhibitor cocktail (Roche). After centrifuging the samples at 12,000 g for 15 min, the supernatants were collected. The total amount of protein was quantified using the Pierce BCA Protein Assay Kit. 30 µg of total protein each were separated by 10% SDS polyacrylamide gel electrophoresis and blotted into PVDF membranes. Then the membranes were probed with primary and secondary antibodies sequentially. The primary antibodies were utilized: anti-FSTL1 (1:1,000), anti-collagen I (1:1,000), anti-SMA (1:1,000), anti-P62 (1:1,000), anti-LC3B (1:1,000), and anti-GAPDH (1:1,000) (Abcam). The densitometry of bands were performed by ImageJ software (version 1.46).

**Lung morphometry**

Lung tissue samples were fixed in a 10% solution of formaldehyde for 24 hours. Then samples were embedded in paraaffin and cut into 4 µm slices. Slices were dewaxed and rehydrated before HE staining. After staining, slides were dehydrated, mounted with neutral gum and observed under a microscope. Mean linear intercept (MIL) was measured from the stained mice lung Sect. 10 random 40x fields from each animal were calculated by direct estimation of MIL based on intercept distribution.²⁶

**Immunohistochemistry**

Immunohistochemistry was performed after dewaxing and rehydration. Lung slices were pretreated with an EDTA-antigen retrieval buffer in a microwave oven, and endogenous peroxidase in tissue was quenched with 3% H₂O₂ for 10 min. Lung slices were blocked with 20% normal fetal bovine serum for 30 min at 37 °C, then incubated with primary and secondary antibodies. The stain was performed using the PV-9000 kit (Zhongshan Golden Bridge Biotechnology Co, China). After dehydration and mounting, slices were observed under a microscope.

**Transmission EM**

Lung tissue samples were fixed with 2.5% glutaraldehyde and postfixed with 1% osmium tetroxide in sodium cacodylate buffer for 2 h at 4 °C. Then the samples were stained with 1% Millipore-filtered uranyl acetate, dehydrated in graded ethanol and propylene oxide. After being embedded in LX-112 medium, samples were thin sectioned (70 nm) using ultra-cut microtome (Leica). Ultrathin sections were stained with 4% uranyl acetate and lead citrate, and sections were examined using an electron microscope (JEM).

**Assessment of lung function**
Lung function was assessed with FlexiVent ventilator (SCIREQ, Canada) for small animals when mice were stable. At 24 h after the final exposure, mice were anesthetized intraperitoneally and tracheostomised. After intubation, mice were mechanically ventilated to assess lung function. Using pressure-volume (PV) loops, lung function was measured including total lung capacity (TLC) and lung compliance (chord compliance, Cchord).

Statistics analysis

Data were presented as mean ± SD. Student’s t-test and ANOVA were used to assess differences in measured variables for group comparisons (at least 3 independent experiments). Statistical analysis was conducted with SPSS 20.0 and GraphPad Prism 5.0, and significance was defined at P < 0.05.

Results

FSTL1 expression and autophagy activation were elevated in COPD patients

Our previous study has shown that FSTL1 may promote EMT and airway remodeling in asthma by activating autophagy. However, it remains unclear whether FSTL1 plays a role in other chronic respiratory diseases, such as COPD. In this study, we found increased circulating FSTL1 in the serum of COPD patients compared with control subjects (Fig. 1a). Airway specimens of COPD patients (Fig. 1b) showed infiltration of neutrophils in airway lumen, epithelial integrity loss, and cilia lodging by HE staining. Meanwhile, the positive areas of FSTL1 and LC3B staining in epithelial cells and mesenchyme were significantly larger than that in control subjects by immunohistochemistry staining (Fig. 1c and 1d). These results indicated that FSTL1 was highly expressed in COPD patients with autophagy activation.

FSTL1 expression in mice was increased in response to CS exposure

To investigate the correlation between FSTL1 and pathogenesis of COPD, we generated a CS-induced mouse model. By performing HE staining and measurement of MLI, the lung specimen of CS exposed mice showed an active inflammatory response and emphysema process, including destruction of lung parenchyma and alveolar walls (Fig. 2a and 2c). Western blotting and immunohistochemistry staining were performed in order to confirm FSTL1 expression after CS exposure. Results showed that epithelial cells and mesenchyme demonstrated positive staining of FSTL1 (Fig. 2b) in CS exposed mice. Consistently, western blotting using lung homogenates showed a higher level of FSTL1 with CS exposure (Fig. 2d and 2e). These results suggest that cigarette smoking may upregulate the expression of FSTL1 in lung tissue, especially in epithelial cell.

CS exposure activates autophagy, promoting airway remodeling and airway inflammation
To elucidate the regulatory role of FSTL1 in CS exposed mice, we detected the biomarkers of airway remodeling, airway inflammation and autophagy in mice model. As expected, collagen and α-SMA were highly expressed in airway specimens of CS exposed mice (Fig. 4a). We also found upregulation of LC3B in lung parenchyma and small airway(Fig. 3a), together with increased LC3B/β ratio and autophagosome formation in airway epithelial cell by transmission electron microscopy(Fig. 3b and 3c), which proved activated autophagy. P62 also increased in CS exposed mice, indicating insufficient autophagic clearance (Fig. 3a). Western blotting analysis of lung total protein was performed and a consistent conclusion was reached (Fig. 3c and 3d, Fig. 4b and 4d). Certain inflammatory cytokines were measured by ELISA to study airway inflammation. As shown in Fig. 4c, levels of TNF-α, IL-8 and LTB4 increased significantly in BALF of CS exposed mice. These results indicate that FSTL1 may promote CS-induced airway remodeling and airway inflammation by regulating autophagy.

**Inhibit autophagy with 3-MA can attenuate airway remodeling and inflammation in CS exposed WT mice**

To further explore the effect of autophagy on COPD, we treated CS exposed mice with 3-methyladenine (3-MA), a chemical inhibitor of PI3K. Under transmission electron microscopy, the formation of autophagosome in epithelial cell was markedly inhibited by 3-MA pretreatment(Fig. 3b). Furthermore, immunohistochemistry staining and western blotting analysis showed a decreased level of LC3B and an increasing level of P62 after 3-MA pretreatment (Fig. 3a 3c and 3d). These results indicate that autophagy in CS exposed mice was suppressed by 3-MA. Meanwhile, 3-MA pretreated mice exhibited lower expression of collagen and α-SMA (Fig. 4a,4b and 4d) and inflammatory mediators mentioned before compared with CS exposed mice(Fig. 4c). Our investigation proved that inhibiting autophagy with 3-MA can attenuate CS-induced airway remodeling and inflammation in WT mice.

**FSTL1 deficiency attenuates autophagy activation in response to CS exposure**

In WT mice model, we found that FSTL1 and autophagy may play a role in the development of COPD. To further examine the effect of FSTL1 on autophagy regulation and COPD pathogenesis, animal model was established using FSTL1+/− mice and FSTL1+/− mice(Fig. 5a). After 12 weeks of exposure to cigarette smoke or air, we detected the level of FSTL1,LC3B,P62 and autophagosome in animal model by immunohistochemistry staining and western blotting analysis. As predicted, LC3B conversion(Fig. 5c and 5d) and autophagosome formation (Fig. 5b) were increased after CS exposure. However, these changes were reduced in CS-FSTL1+/− mice than CS-FSTL1+/− mice, illustrating that haplodeletion of FSTL1 attenuated CS-induced autophagy activation. The most significant elevation of P62 was observed in CS-FSTL1+/− mice, and haplodeletion of FSTL1 also mitigated the effect of CS exposure(Fig. 5a, 5c and 5d). According to these evidence, FSTL1 deficiency can not only protest against CS-induced autophagy activation but also improve autophagic clearance.

**FSTL1 deficiency relieves airway remodeling and inflammation in response to CS exposure**
Compared with FSTL1^{flox/+} mice, there was a more subdued increase of collagen and α-SMA in FSTL1^{+/−} mice after CS exposure by immunohistochemistry staining (Fig. 6a) and western blotting analysis (Fig. 6c and 6d). Meanwhile, after CS exposure, the increase of IL-8, LTB4 and TNF-α in BALF of FSTL1^{+/−} mice was lower than that of FSTL1^{flox/+} mice (Fig. 6b), indicating that airway inflammation was alleviated. These results demonstrate that knockdown of FSTL1 alleviates CS-induced airway remodeling and inflammation in mice.

**Both FSTL1 deficiency and autophagy inhibitor rescue lung function decline in CS exposed mice**

In order to verify the effect of FSTL1 and autophagy on lung function of CS exposed mice, we measured total lung capacity and lung compliance using a ventilator for small animals after the final exposure. Both 3-MA pretreated WT mice and FSTL1^{+/−} mice showed attenuated lung function decline in response to CS exposure. Hyperinflation occurred in CS-WT mice and CS-FSTL1^{flox/+} mice as the total lung capacity (TLC) and lung compliance increased after chronic CS exposure. However, TLC (Fig. 7a) and Cchord (Fig. 7b) did not rise significantly in 3-MA pretreated WT mice and FSTL1^{+/−} mice after CS exposure. The data suggest that FSTL1 deficiency can protest against the decline of lung function after CS exposure as autophagy inhibitor did.

**Discussion**

The development of COPD involves inducible responses to inhaled particles, including cigarette smoke, and stress triggered by cigarette smoke exposure can induce autophagy in lung tissue. In this study, we report that FSTL1 is highly expressed in COPD patients together with autophagy activation, airway inflammation and airway remodeling. In both COPD patients and CS exposed animal model, we found the level of FSTL1 was positively related to overactive autophagy. Moreover, autophagy inhibition with 3-MA can attenuate airway remodeling and inflammation to a certain extent in CS exposed mice. By establishing FSTL1^{+/−} mice model, we proved that the haplodeletion of FSTL1 had a repressive effect on autophagy, indicating that FSTL1 might play a vital role in the activation of autophagy. In conclusion, our study has found a link between FSTL1, autophagy and the pathogenesis of COPD, supporting our hypothesis that FSTL1 modulates CS-induced autophagy and is involved in COPD process.

FSTL1 is implicated in various biological and pathological processes, including apoptosis, autophagy, proliferation, differentiation and migration. Generated mainly by mesenchymal cells (fibroblasts, chondrocytes, osteocytes, etc.), FSTL1 affects immunomodulation, tumorigenesis, fibrogenesis and organ development via multiple signal pathways. As an antagonist of BMP4 signaling pathway, FSTL1 plays a crucial part in the embryogenesis of lung and alveolar, thus FSTL1^{−/−} mice showed postnatal lethality due to respiratory failure. There is growing evidence that FSTL-1 plays an essential role in respiratory diseases. Recent studies prove that FSTL1 participates in lung injury as it is secreted in response to bleomycin, silica, radiation and other lung injury inducers. Besides, FSTL1 have an
association with airway remodeling in chronic airway diseases\textsuperscript{33}. Our previous study suggested that FSTL1 was positively linked to thickened RBM and smooth muscle mass in asthmatics. Moreover, FSTL1 can induce EMT and airway remodeling in asthma\textsuperscript{34}. Several FSTL1 SNPs were found corresponded to COPD and lung function, and FSTL-1 deficiency might protect mice from cigarette smoke induced emphysema\textsuperscript{35}. In the present study, we further unravel the role of FSTL1 in the pathogenesis of COPD. The increased level of FSTL1 in COPD is linked to overactive autophagy, aggravating airway remodeling and airway inflammation. Besides, haplodeletion of FSTL1 in CS exposed mice abate airway remodeling and airway inflammation through inhibiting CS-induced autophagy.

Autophagy is a lysosome-dependent degradation of microorganisms, cellular proteins and organelles in order to keep homeostatic balance, consisting of macroautophagy, microautophagy and selected autophagy\textsuperscript{36,37}. LC3B (microtubule associated protein 1 light chain 3 beta), as one of autophagy-related (ATG) proteins, represents autophagosome formation by the conversion from LC3B-I to LC3B-II\textsuperscript{38,39}. Z.H. Chen \textit{et al} reported that LC3B exerted a critical propathogenic role in the development of CS-induced emphysema\textsuperscript{40}. P62, also known as sequestosome 1 (SQSTM1), which directly conjugated to LC3B, is self-degraded by autophagy and indicates insufficient autophagic clearance\textsuperscript{41,42}. Our data suggest a higher LC3B II/I ratio and P62 expression in CS exposed animal model. Also, the autophagosome formation was more obvious after CS exposure. These results revealed that CS triggered overactive autophagy and insufficient autophagic clearance in lung. Meanwhile, pretreatment with 3-MA significantly reduced CS-induced autophagy and disease progression. It is well known that autophagy plays a critical role in pulmonary inflammation and pathogenesis of numerous chronic lung disease\textsuperscript{13}. However, in COPD which undergoes prolonged inflammation and stress, the function of autophagy is more complicated.

There is growing evidence that dysregulated autophagy is tied to pathogenesis of COPD. Some studies suggest that autophagy contributes to COPD progress. Increased autophagic proteins were found in lung tissue from COPD patients\textsuperscript{43}. In vitro, autophagy was considered as an early event in COPD progression\textsuperscript{43}. CS-induced autophagy in epithelial cells promotes the production of TNF-\(\alpha\), IL-6 and IL-8 and lymphocyte recruitment into the lung\textsuperscript{44}. It appears that CS initiate and prompt airway inflammation by increasing autophagosomal turnover (flux) and therefore result in epithelial cell apoptosis and death\textsuperscript{16,17,40,43,45}. Moreover, recent advances deem autophagy has a potential impact on airway fibrosis\textsuperscript{46}. Deficiency of autophagy alleviates CS-induced cilia shortening \textit{in vitro} and reduces profibrotic signaling pathway and ECM release \textit{in vitro}\textsuperscript{45}. \textit{In vivo} experiment, we validated that inhibition of autophagy activation with 3-MA mitigated CS-induced airway remodeling and airway inflammation, further enriching evidence that overactive autophagy exacerbates COPD progression. On the other hand, there exist other mechanisms of dysregulated autophagy in COPD. Functional autophagy is critical to degrade damaged organelles and proteins and maintain homeostasis. Some research indicates that autophagy impairment induced by ROS from CS and mitochondria can accelerate lung aging and emphysema exacerbations\textsuperscript{47}. Inadequate autophagy can induce senescence in COPD and also contribute to development of idiopathic
pulmonary fibrosis$^{48,49}$. Autophagy augmentation appears to be a therapeutic target for alleviating aging and COPD progress$^{50}$. In our study, P62 increased after CS exposure, suggesting impaired autophagy while overactive autophagy was found. Dysregulated autophagy in COPD pathogenesis may operate in two extremes. Since autophagy is a well-known dynamic and complicated process, innovative methods and specific regulators should be developed to investigate autophagy in “real-time”.

In our research, FSTL1 was elevated together with autophagosome formation and autophagic proteins in both COPD patients and CS exposed animal model. Pretreatment with autophagic inhibitor in WT mice could alleviate CS-induced airway inflammation, airway remodeling and impaired lung function. In FSTL1$^{+/−}$ mice, deficiency of FSTL1 also bated CS-induced autophagy activation and adverse response to CS in lung tissue. These results indicate that FSTL1 may modulate autophagy by certain signaling pathways in COPD. From the existing study, we can learn that FSTL1 have crosstalk with several autophagic signaling pathways. Via DIP2A receptor, FSTL1 is able to activate Akt pathway and finally attenuate apoptosis after MCAO in Rats$^{51}$. In cardiovascular disease, FSTL1 has been implicated in the activation of PI3K/Akt signaling, exhibiting protective effects$^{52−54}$. Furthermore, FSTL1 is involved in the activation of AMPK signaling pathway in cardiac and renal disease$^{55,56}$. These studies shed light on the correlation between FSTL1 and regulation of autophagy. However, there exists some limitations. The present study cannot demonstrate a complete mechanism of FSTL1, dysregulated autophagy and COPD. We still require additional work including in vitro experiments with more accurate autophagic regulators to study autophagy, and investigate the mechanism of how FSTL1 exerts the effect on autophagy and leads to COPD.

**Conclusions**

In this study, we proved that FSTL1 promotes CS-induced COPD process by regulating autophagy. In conclusion, our study demonstrates the important role of FSTL1 and autophagy in COPD occurrence and progression, providing potential avenues for therapeutic targeting of COPD.

Figures
a) Serum concentration of FSTL1 in patients (ng/ml)

b) HE

CON  COPD

FSTL1

CON  COPD

LC3B

CON  COPD
FSTL1 was highly expressed in COPD patients and correlated with autophagy. a: FSTL1 level was significantly higher in the serum of COPD patients (n=28) compared with control (n=25) (ELISA). b: Airway specimens of COPD showed neutrophil infiltration in airway lumen, epithelial integrity loss, and cilia lodging (HE staining, 400x). c: The positive area of FSTL1 in airway specimens of COPD patients was significantly larger than that of control subjects (immunohistochemistry staining, 400x). d: The positive area of LC3B in airway specimens was significantly larger than control subjects (immunohistochemistry staining, 400x). Median of each group is presented. * difference between control and COPD group, p<0.05, ***p<0.001, t-test. Abbreviations: CON, control.
Figure 2

CS exposed mice exhibit higher expression of FSTL1. a&c: The lung tissue of CS-WT mice showed an active inflammatory process, small airway obstruction and augmented airspace (HE staining, 200x). Mean linear intercept was measured (10 random fields each mouse). b: The positive area of FSTL1 in lung tissue of CS exposed mice was significantly larger than that in control group (immunohistochemistry, 400x). d&e: The protein level of FSTL1 in lung of CS-WT mice is higher than control group (western blotting). All of the experiments were repeated independently at least 3 times. *difference between CON-WT and CS-
WT, p<0.05, ***p<0.001; t-test. Abbreviations: CS, cigarette smoke. WT, wild type. ANOVA, analysis of variance.
Figure 3

Dysregulation of autophagy in CS exposed mice. a: The positive area of LC3B and P62 in lung tissue of CS-WT mice was significantly larger than that in control group, and injection with 3-MA lighten the
differences. (immunohistochemistry, 400x). b: Autophagosomes formation was enhanced in CS-WT mice and alleviated by 3-MA pretreatment (transmission electron microscopy). c&d: The protein level of LC3B and P62 in each group (Western blotting). All of the experiments were repeated independently at least 3 times. *difference between CON-WT and CS-WT, p<0.05, **p<0.01, ***p<0.001; #difference between CS-WT and CS+3MA-WT, p<0.05; one-way ANOVA, t-test. Abbreviations: CS, cigarette smoke. WT, wild type. 3-MA, 3-methyladenine. ANOVA, analysis of variance.
Figure 4

CS-induced autophagy leads to airway remodeling and airway inflammation. a: The positive area of collagen I and α-SMA in lung tissue of CS-WT mice was significantly larger than control group, and 3-MA
injection lightened airway remodeling (Immunohistochemistry, 400x). b&d: The protein level of collagen and α-SMA in each group (Western blotting). c: Levels of TNF-α, IL-8 and LTB4 increased significantly in BALF of CS-WT mice and 3-MA injection alleviated the change (ELISA). All of the experiments were repeated independently at least 3 times. * difference between CON-WT and CS-WT, p<0.05, **p<0.01, ***p<0.001; # difference between CS-WT and CS+3MA-WT, p<0.05; one-way ANOVA, t-test. Abbreviations: CS, cigarette smoke. WT, wild type. 3-MA, 3-methyladenine. BALF, bronchoalveolar lavage fluid. ANOVA, analysis of variance.

Figure 5

The haplodeletion of FSTL1 attenuates autophagy in CS exposed model. a: The staining of FSTL1 and autophagic proteins LC3B, P62 in lung tissue of FSTL1+/- and FSTL1flox/+ mice with or without CS exposure (Immunohistochemistry, 400x). b: Autophagosome formation was inhibited in CS-FSTL1+/- mice. (Transmission electron microscopy). c&d: The protein level of FSTL1, LC3B and P62 in each group (Western blotting). All of the experiments were repeated independently at least 3 times. * p<0.05, ** p<0.01 *** p<0.001; one-way ANOVA, t-test. Abbreviations: CS, cigarette smoke.
Figure 6

FSTL1 deficiency abates airway remodeling and airway inflammation. a: The positive area of collagen I and α-SMA in lung tissue of FSTL1+/– and FSTL1 flox/+ mice with or without CS exposure (immunohistochemistry, 400x). b: Levels of TNF-α, IL-8 and LTB4 increased significantly in BALF of CS-FSTL1 flox/+ mice than CS-FSTL1+/– mice (ELISA). c&d: The protein level of collagen I and α-SMA in each group (western blotting). All of the experiments were repeated independently at least 3 times. * p<0.05, ** p<0.01; one-way ANOVA. Abbreviations: CS, cigarette smoke. BALF, bronchoalveolar lavage fluid.
Figure 7

FSTL1 deficiency and autophagy inhibitor both alleviate lung function decline in CS exposed mice. 

a: After CS exposure, total lung capacity did not increase in 3-MA pretreatment mice, and FSTL1+/− mice showed a similar protective effect as 3-MA versus FSTL1flox/+ mice. 
b: After CS exposure, lung compliance did not increase sharply in 3-MA pretreatment mice, and FSTL1+/− mice showed a similar protective effect as 3-MA versus FSTL1flox/+ mice. All of the experiments were repeated independently at least 3 times. *difference between CON-WT and CS-WT, FSTL1flox/+ and CS-FSTL1flox/+ , p<0.05, **p<0.01; #difference between CS-WT and CS+3MA-WT, CS-FSTL1+/− and CS-FSTL1flox/+ , p<0.05; one-way ANOVA. Abbreviations: CS, cigarette smoke. 3-MA, 3-methyladenine. CON, control. WT, wild type.
