Abstract

We present an introduction to the geometry of higher order vector and co–vector bundles (including higher order generalizations of the Finsler geometry and Kaluza–Klein gravity) and review the basic results on Clifford and spinor structures on spaces with generic local anisotropy modeled by anholonomic frames with associated nonlinear connection structures. We emphasize strong arguments for application of Finsler like geometries in modern string and gravity theory and noncommutative geometry and noncommutative field theory and gravity.

AMS Subject Classification: 15A66, 58B20, 81D25, 53C60, 83C60, 83E15

Keywords: Clifford structures, nonlinear connection, spinor, higher order (co-)vector bundle, generalized Finsler geometry.
1 Introduction

Nowadays, it has been established an interest to non–Riemannian geometries derived in the low energy string theory [9], noncommutative geometry [6, 50] and quantum groups [18]. Various types of Finsler like structures can be parametrized by generic off–diagonal metrics, which can not be diagonalized by coordinate transforms but only by anholonomic maps with associated nonlinear connection (in brief, N–connection). Such structures may be defined as exact solutions of gravitational field equations in the Einstein gravity and its generalizations [16, 50, 47], for instance, in the metric–affine [13] Riemann–Cartan gravity [24]. Finsler like configurations are considered in locally anisotropic thermodynamics and kinetics and related stochastic processes [45] and (super) string theory [36, 42, 43].

The following natural step in these lines is to elucidate the theory of spinors in effectively derived Finsler geometries and to relate this formalism of Clifford structures to non–commutative Finsler geometry. It should be noted that the rigorous definition of spinors for Finsler spaces and generalizations was not a trivial task because (on such spaces) there are not defined even local groups of authomorphisms. The problem was solved in Refs. [38, 39, 44] by adapting the geometric constructions with respect to anholonomic frames with associated N–connection structure. The aim of this work is to outline the geometry of generalized Finsler spinors in a form more oriented to applications in modern mathematical physics.

We start with some historical remarks: The spinors studied by mathematicians and physicists are connected with the general theory of Clifford spaces introduced in 1876 [7]. The theory of spinors and Clifford algebras play a major role in contemporary physics and mathematics. The spinors were discovered by Élie Cartan in 1913 in mathematical form in his researches on representation group theory [5]: he showed that spinors furnish a linear representation of the groups of rotations of a space of arbitrary dimensions. Physicists Pauli [26] and Dirac [10] (in 1927, respectively, for the three–dimensional and four–dimensional space–time) introduced spinors for the representation of the wave functions. In general relativity theory spinors and the Dirac equations on (pseudo) Riemannian spaces were defined in 1929 by H. Weyl [51], V. Fock [11] and E. Schrödinger [29]. The books [27] by R. Penrose and W. Rindler monograph summarize the spinor and twistor methods in space–time geometry (see additional references [15] on Clifford structures and spinor theory).

Spinor variables were introduced in Finsler geometries by Y. Takano in 1983 [34] where he dismissed anisotropic dependencies not only on vectors on the tangent bundle but on some spinor variables in a spinor bundle on a space–time manifold. Then generalized Finsler geometries, with spinor variables, were developed by T. Ono and Y. Takano in a series of publications during 1990–1993 [25]. The next steps were investigations of anisotropic and deformed geometries with spinor and vector variables and applications in gauge and gravity theories elaborated by P. Stavrinos and his students, S. Koutroubis, P. Manouselis, and V. Balan starting from 1994 [2, 32, 33]. In those works the authors assumed that some spinor variables may be introduced in a Finsler-like way but they did not relate the Finsler metric to a Clifford structure and restricted the spinor–gauge Finsler constructions only for antisymmetric spinor metrics on two–spinor fibers with possible generalizations to four dimensional Dirac spinors.

Isotopic spinors, related with $SU(2)$ internal structural groups, were considered in gen-
eralized Finsler gravity and gauge theories also by G. Asanov and S. Ponomarenko [2], in 1988. In that book, and in other papers on Finsler geometry with spinor variables, the authors did not investigate the possibility of introducing a rigorous mathematical definition of spinors on spaces with generic local anisotropy.

An alternative approach to spinor differential geometry and generalized Finsler spaces was elaborated, starting from 1994, in a series of papers and communications by S. Vacaru and co–authors [37, 39, 40, 48]. This direction originates from Clifford algebras and Clifford bundles [12] and Penrose's spinor and twistor space–time geometry [27], which were re–considered for the case of nearly autoparallel maps (generalized conformal transforms) in Refs. [35]. In the works [37, 38, 39, 40, 48], a rigorous definition of spinors for Finsler spaces, and their generalizations, was given. It was proven that a Finsler, or Lagrange, metric (in a tangent, or, more generally, in a vector bundle) induces naturally a distinguished Clifford (spinor) structure which is locally adapted to the nonlinear connection structure. Such spinor spaces could be defined for arbitrary dimensions of base and fiber subspaces, their spinor metrics are symmetric, antisymmetric or nonsymmetric, depending on the corresponding base and fiber dimensions. That work resulted in formation of the spinor differential geometry of generalized Finsler spaces and developed a number of geometric applications to the theory of gravitational and matter field interactions with generic local anisotropy.

The geometry of anisotropic spinors and (distinguished by nonlinear connections) Clifford structures was elaborated for higher order anisotropic spaces [39, 41, 43] and, more recently, for Hamilton and Lagrange spaces [50].

We emphasize that the theory of anisotropic spinors may be related not only to generalized Finsler, Lagrange, Cartan and Hamilton spaces or their higher order generalizations, but also to anholonomic frames with associated nonlinear connections which appear naturally even in (pseudo) Riemannian and Riemann–Cartan geometries if off–diagonal metrics are considered [16]. In order to construct exact solutions of the Einstein equations in general relativity and extra dimension gravity (for lower dimensions see [45]), it is more convenient to diagonalize space–time metrics by using some anholonomic transforms. As a result one induces locally anisotropic structures on space–time which are related to anholonomic (anisotropic) spinor structures.

The main purpose of the present review is to present a detailed summary and new results on spinor differential geometry for generalized Finsler spaces and (pseudo) Riemannian space–times provided with anholonomic frame and associated nonlinear connection structure, to discuss and compare the existing approaches and to consider applications to modern gravity and gauge theories.

2 (Co) Vector Bundles and N–Connections

We outline the basic definitions and denotations for the vector and tangent (and theirs dual spaces) bundles and higher order vector/covector bundle geometry. In this work, we consider that the space–time geometry can be modeled both on a (pseudo) Riemannian manifold $V^{[n+m]}$ of dimension $n + m$ and/or on a vector bundle (or its dual, covector bundle) being, for simplicity, locally trivial with a base space $M$ of dimension $n$ and a typical
fiber $F$ (cofiber $F^*$) of dimension $m$, or as a higher order extended vector/covector bundle (we follow the geometric constructions and definitions of monographs [23, 22] which were generalized for vector superbundles in Refs. [42, 43]). Such (pseudo) Riemannian spaces and/or vector/covector bundles enabled with compatible fibered and/or anholonomic structures are called anisotropic space–times. If the anholonomic structure with associated nonlinear connection is modeled on higher order vector/covector bundles we use the term of higher order anisotropic space–time. In this section, we usually shall omit proofs which can be found in the mentioned monographs [23, 22, 43].

2.1 (Co) vector and tangent bundles

A locally trivial vector bundle, in brief, $v$–bundle, $\mathcal{E} = (E, \pi, M, Gr, F)$ is introduced as a set of spaces and surjective map with the properties that a real vector space $F = \mathbb{R}^m$ (dim $F = m$, $\mathbb{R}$ denotes the real number field) defines the typical fiber, the structural group is chosen to be the group of automorphisms of $\mathbb{R}^m$, i.e. $Gr = GL(m, \mathbb{R})$, and $\pi : E \to M$ is a differentiable surjection of a differentiable manifold $E$ (total space, dim $E = n + m$) to a differentiable manifold $M$ (base space, dim $M = n$). The local coordinates on $\mathcal{E}$ are denoted $u^\alpha = (x^i, y^a)$, or in brief $u = (x, y)$ (the Latin indices $i, j, k, ... = 1, 2, ..., n$ define coordinates of geometrical objects with respect to a local frame on base space $M$; the Latin indices $a, b, c, ... = 1, 2, ..., m$ define fiber coordinates of geometrical objects and the Greek indices $\alpha, \beta, \gamma, ...$ are considered as cumulative ones for coordinates of objects defined on the total space of a $v$–bundle).

Coordinate transforms $u^\alpha' = u^\alpha'(u^\alpha)$ on a $v$–bundle $\mathcal{E}$ are defined $(x^i, y^a) \to (x'^i, y'^a)$, where

\[ x'^i = x^i' (x^i), \quad y'^a = K_a^i (x^i) y^a \]  

(1)

and matrix $K_a^i(x^i) \in GL(m, \mathbb{R})$ are functions of necessary smoothness class.

A local coordinate parametrization of $v$–bundle $\mathcal{E}$ naturally defines a coordinate basis

\[ \partial_\alpha = \frac{\partial}{\partial u^\alpha} = \left( \partial_i = \frac{\partial}{\partial x^i}, \partial_a = \frac{\partial}{\partial y^a} \right), \]  

(2)

and the reciprocal to (2) coordinate basis

\[ d^\alpha = du^\alpha = (d^i = dx^i, d^a = dy^a) \]  

(3)

which is uniquely defined from the equations $d^\alpha \circ \partial_\beta = \delta^\alpha_\beta$, where $\delta^\alpha_\beta$ is the Kronecker symbol and by ”$\circ$” we denote the inner (scalar) product in the tangent bundle $T\mathcal{E}$.

A tangent bundle (in brief, $t$–bundle) $(TM, \pi, M)$ to a manifold $M$ can be defined as a particular case of a $v$–bundle when the dimension of the base and fiber spaces (the last one considered as the tangent subspace) are identic, $n = m$. In this case both type of indices $i, k, ...$ and $a, b, ...$ take the same values $1, 2, ..., n$. For $t$–bundles the matrices of fiber coordinates transforms from (1) can be written $K^i_a = \partial x'^i / \partial x^i$.

We shall also use the concept of covector bundle, (in brief, $cv$–bundles) $\mathcal{E}^* = (\tilde{E}, \pi^*, M, Gr, F^*)$, which is introduced as a dual vector bundle for which the typical fiber $F^*$ (cofiber) is considered to be the dual vector space (covector space) to the vector

4
space $E$. The fiber coordinates $p_a$ of $\tilde{E}$ are dual to $y^a$ in $E$. The local coordinates on total space $\tilde{E}$ are denoted $\tilde{u} = (x, p) = (x^i, p_a)$. The coordinate transform on $\tilde{E}$, $\tilde{u} = (x^i, p_a) \rightarrow \tilde{u}' = (x^{i'}, p_{a'})$, are written

$$x^{i'} = x^{i'}(x^i), \quad p_{a'} = K^{a'}_a(x^i)p_a. \quad (4)$$

The coordinate bases on $E^*$ are denoted

$$\tilde{\partial}_\alpha = \frac{\tilde{\partial}}{\tilde{\partial}u^\alpha} = \left( \partial_i = \frac{\partial}{\partial x^i}, \tilde{\partial}^a = \frac{\tilde{\partial}}{\tilde{\partial}p_a} \right) \quad (5)$$

and

$$\tilde{d}^\alpha = \tilde{d}u^\alpha = \left( d^i = dx^i, \tilde{d}_a = dp_a \right). \quad (6)$$

We use "breve" symbols in order to distinguish the geometrical objects on a cv–bundle $E^*$ from those on a v–bundle $E$.

As a particular case with the same dimension of base space and cofiber one obtains the cotangent bundle $(T^*M, \pi^*, M)$, in brief, ct–bundle, being dual to $TM$. The fibre coordinates $p_i$ of $T^*M$ are dual to $y^i$ in $TM$. The coordinate transforms (4) on $T^*M$ are stated by some matrices $K^{k'}_k(x^i) = \partial x^{k'}/\partial x^k$.

In our further considerations we shall distinguish the base and cofiber indices.

### 2.2 Higher order (co) vector bundles

The geometry of higher order tangent and cotangent bundles provided with nonlinear connection structure was elaborated in Refs. [22] in order to geometrize the higher order Lagrange and Hamilton mechanics. In this case we have base spaces and fibers of the same dimension. To develop the approach to modern high energy physics (in superstring and Kaluza–Klein theories), we introduced (in Refs [39, 44, 43, 42]) the concept of higher order vector bundle with the fibers consisting from finite ‘shells” of vector, or covector, spaces of different dimensions not obligatory coinciding with the base space dimension.

**Definition 2.1.** A distinguished vector/covector space, in brief dvc–space, of type

$$\tilde{F} = F[v(1), v(2), cv(3), \ldots, cv(z - 1), v(z)] \quad (7)$$

is a vector space decomposed into an invariant oriented direct sum

$$\tilde{F} = F_{(1)} \oplus F_{(2)} \oplus F^*_{(3)} \oplus \ldots \oplus F^*_{(z-1)} \oplus F_{(z)}$$

of vector spaces $F_{(1)}, F_{(2)}, \ldots, F_{(z)}$ of respective dimensions

$$\text{dim}F_{(1)} = m_1, \text{dim}F_{(2)} = m_2, \ldots, \text{dim}F_{(z)} = m_z$$

and of covector spaces $F^*_{(3)}, \ldots, F^*_{(z-1)}$ of respective dimensions

$$\text{dim}F^*_{(3)} = m_3^*, \ldots, \text{dim}F^*_{(z-1)} = m_{(z-1)}^*.$$
As a particular case we obtain a distinguished vector space, in brief dv–space (a distinguished covector space, in brief dcv–space), if all components of the sum are vector (covector) spaces. We note that we have fixed, for simplicity, an orientation of (co) vector subspaces like in (7).

Coordinates on \( \widetilde{F} \) are denoted
\[
\tilde{y} = (y_1, y_2, p_3, \ldots, p_{(z-1)}, y_z) = (y^{a_1}, y^{a_2}, p_{a_3}, \ldots, p_{a_{z-1}}, y^{a_z}),
\]
where indices run correspondingly the values \( a_1 = 1, 2, \ldots, m_1; a_2 = 1, 2, \ldots, m_2, \ldots, a_z = 1, 2, \ldots, m_z. \)

**Definition 2.2.** A higher order vector/covector bundle (in brief, hvc–bundle) of type \( \widetilde{E} = \widetilde{E}[v(1), v(2), cv(3), \ldots, cv(z - 1), v(z)] \) is a vector bundle \( \widetilde{E} = (\tilde{E}, \varphi^{<d>}, \tilde{F}, M) \) with corresponding total, \( \tilde{E} \), and base, \( M \), spaces, surjective projection \( \varphi^{<d>} : \tilde{E} \to M \) and typical fiber \( \tilde{F} \).

We define the higher order vector (covector) bundles, in brief, hv–bundles (in brief, hcv–bundles), if the typical fibre is a dv–space (dcv–space) as particular cases of the hvc–bundles.

A hvc–bundle is constructed as an oriented set of enveloping ’shell by shell’ v–bundles and/or cv–bundles,
\[
\varphi^{<s>} : \tilde{E}^{<s>} \to \tilde{E}^{<s-1>},
\]
where we use the index \( <s> = 0, 1, 2, \ldots, z \) in order to enumerate the shells, when \( \tilde{E}^{<0>} = M. \) Local coordinates on \( \tilde{E}^{<s>} \) are denoted
\[
\tilde{u}^{(s)} = (x, \tilde{y}^{<s>}) = (x, y_1, y_2, p_3, \ldots, y_z) = (x^i, y^{a_1}, y^{a_2}, p_{a_3}, \ldots, y^{a_z}).
\]

If \( <s> = <z> \) we obtain a complete coordinate system on \( \tilde{E} \) denoted in brief
\[
\tilde{u} = (x, \tilde{y}) = \tilde{u}^{(a)} = (x^i = y^{a_0}, y^{a_1}, y^{a_2}, p_{a_3}, \ldots, y^{a_z}).
\]

We shall use the general commutative indices \( \alpha, \beta, \ldots \) for objects on hvc—bundles which are marked by tilde, like \( \tilde{u}, \tilde{u}^{(a)}, \ldots, \tilde{E}^{<s>}, \ldots \)

The coordinate bases on \( \tilde{E} \) are denoted
\[
\partial_\alpha = \frac{\partial}{\partial \tilde{u}^\alpha} = \left( \partial_i = \frac{\partial}{\partial x^i}, \partial_{a_1} = \frac{\partial}{\partial y^{a_1}}, \partial_{a_2} = \frac{\partial}{\partial y^{a_2}}, \partial_{a_3} = \frac{\partial}{\partial p_{a_3}}, \ldots, \partial_{a_z} = \frac{\partial}{\partial y^{a_z}} \right) \quad \text{(8)}
\]
and
\[
\tilde{d}_\alpha = \tilde{d} \tilde{u}^{(a)} = \left( \tilde{d}^i = dx^i, \tilde{d}^{a_1} = dy^{a_1}, \tilde{d}^{a_2} = dy^{a_2}, \tilde{d}_{a_3} = dp_{a_3}, \ldots, \tilde{d}^{a_z} = dy^{a_z} \right). \quad \text{(9)}
\]

We give two examples of higher order tangent / cotangent bundles (when the dimensions of fibers/cofibers coincide with the dimension of bundle space, see Refs. [22]).
2.2.1 Osculator bundle

The \( k \)-osculator bundle is identified with the \( k \)-tangent bundle \( (T^k M, p^{(k)}, M) \) of a \( n \)-dimensional manifold \( M \). We denote the local coordinates \( \tilde{u}^\alpha = (x^i, y_{(1)}^i, ..., y_{(k)}^i) \), where we have identified \( y_{(1)}^i \simeq y^{n_1}, ..., y_{(k)}^i \simeq y^n \), \( k = z \), in order to have similarity with denotations from [22]. The coordinate transforms \( \tilde{u}^{\alpha'} \rightarrow \tilde{u}^{\alpha'} (\tilde{u}^\alpha) \) preserving the structure of such higher order vector bundles are parametrized

\[
x'^\alpha = x'^\alpha (x^i), \quad \det \left( \frac{\partial x'^\alpha}{\partial x^i} \right) \neq 0,
\]

\[
y'^{i(1)} = \frac{\partial x'^i}{\partial x^i} y_{(1)}^i, \quad 2y'^{i(2)} = \frac{\partial y'^{i(1)}_{(1)}}{\partial x^i} y_{(1)}^i + 2 \frac{\partial y'^{i(1)}_{(2)}}{\partial y_{(1)}^i} y_{(2)}^i,
\]

\[\begin{array}{c}
\vdots \\
k y'^{i(k)} = \frac{\partial y'^{i(1)}}{\partial x^i} y_{(1)}^i + \ldots + k \frac{\partial y'^{i(k-1)}}{\partial y_{(k-1)}^i} y_{(k)}^i,
\end{array}\]

where the equalities

\[
\frac{\partial y'^{i(s)}}{\partial x^i} = \frac{\partial y'^{i(s+1)}}{\partial y'^{i(1)}_{(1)}} = \ldots = \frac{\partial y'^{i(k)}}{\partial y'^{i(k-s)}}
\]

hold for \( s = 0, ..., k - 1 \) and \( y_{(0)}^i = x^i \).

The natural coordinate frame on \( (T^k M, p^{(k)}, M) \) is defined as \( \tilde{\alpha} = (\frac{\partial}{\partial x^i}, \frac{\partial}{\partial y_{(1)}^i}, ..., \frac{\partial}{\partial y_{(k)}^i}) \) and the coframe is \( \tilde{\alpha} = (dx^i, dy_{(1)}^i, ..., dy_{(k)}^i) \). These formulas are respectively some particular cases of [8] and [9].

2.2.2 The dual bundle of \( k \)-osculator bundle

This higher order vector/covector bundle, denoted as \( (T^{*k} M, p^{*k}, M) \), is defined as the dual bundle to the \( k \)-tangent bundle \( (T^k M, p^k, M) \). The local coordinates (parametrized as in the previous paragraph) are

\[
\tilde{u} = (x, y_{(1)}, ..., y_{(k-1)}, p) = (x^i, y_{(1)}^i, ..., y_{(k-1)}^i, p_i) \in T^{*k} M.
\]

The coordinate transforms on \( (T^{*k} M, p^{*k}, M) \) are

\[
x'^\alpha = x'^\alpha (x^i), \quad \det \left( \frac{\partial x'^\alpha}{\partial x^i} \right) \neq 0,
\]

\[
y'^{i(1)} = \frac{\partial x'^i}{\partial x^i} y_{(1)}^i, \quad 2y'^{i(2)} = \frac{\partial y'^{i(1)}_{(1)}}{\partial x^i} y_{(1)}^i + 2 \frac{\partial y'^{i(1)}_{(2)}}{\partial y_{(1)}^i} y_{(2)}^i,
\]

\[\begin{array}{c}
\vdots \\
(k - 1)y'^{i(k-1)} = \frac{\partial y'^{i(k-2)}}{\partial x^i} y_{(1)}^i + \ldots + k \frac{\partial y'^{i(k-1)}}{\partial y_{(k-2)}^i} y_{(k-1)}^i, \quad p_i = \frac{\partial x^i}{\partial x^i} p_i,
\end{array}\]
where the equalities
\[ \frac{\partial y^i_{(s)}}{\partial x^i} = \frac{\partial y^i_{(s+1)}}{\partial y^i_{(1)}} = \ldots = \frac{\partial y^i_{(k-1)}}{\partial y^i_{(k-1-s)}} \]
hold for \( s = 0, \ldots, k-2 \) and \( y^i_{(0)} = x^i \).

The natural coordinate frame on \( (T^*kM, p^*(k), M) \) is written in the form
\[ \tilde{\partial}_\alpha = (\partial_{x^i}, \partial_{y^i_{(1)}}, \ldots, \partial_{y^i_{(k-1)}}, \partial_{p^i}) \] and the coframe is written \( \tilde{d}_\alpha = (dx^i, dy^i_{(1)}, \ldots, dy^i_{(k-1)}, dp^i) \).

These formulas are, respectively, certain particular cases of \( (8) \) and \( (9) \).

### 2.3 Nonlinear Connections

The concept of nonlinear connection, in brief, N-connection, is fundamental in the geometry of vector bundles and anisotropic spaces (see a detailed study and basic references in [23] and, for supersymmetric and/or spinor bundles in [43, 49, 42]). A rigorous mathematical definition is possible by using the formalism of exact sequences of vector bundles.

#### 2.3.1 N-connections in vector bundles

Let \( \mathcal{E} = (E, p, M) \) be a v–bundle with typical fiber \( \mathcal{R}^m \) and \( \pi^T : TE \rightarrow TM \) being the differential of the map \( P \) which is a fibre–preserving morphism of the tangent bundle \( TE, \tau_E, E \rightarrow E \) and of tangent bundle \( (TM, \tau, M) \rightarrow M \). The kernel of the vector bundle morphism, denoted as \( (VE, \tau_Y, E) \), is called the vertical subbundle over \( E \), which is a vector subbundle of the vector bundle \( (TE, \tau_E, E) \).

A vector \( X_u \) tangent to a point \( u \in E \) is locally written as \( (x, y, X, Y) = (x^i, y^a, X^i, Y^a) \), where the coordinates \( (X^i, Y^a) \) are defined by the equality \( X_u = X^i \partial_i + Y^a \partial_a \). We have \( \pi^T(x, y, X, Y) = (x, X) \). Thus the submanifold \( VE \) contains the elements which are locally represented as \( (x, y, 0, Y) \).

**Definition 2.3.** A nonlinear connection \( N \) in a vector bundle \( \mathcal{E} = (E, \pi, M) \) is the splitting on the left of the exact sequence
\[ 0 \rightarrow VE \rightarrow TE \rightarrow TE/VE \rightarrow 0 \]
where \( TE/VE \) is the factor bundle.

By definition \( (2.3) \) it is defined a morphism of vector bundles \( C : TE \rightarrow VE \) such the superposition of maps \( C \circ i \) is the identity on \( VE \), where \( i : VE \rightarrow VE \). The kernel of the morphism \( C \) is a vector subbundle of \( (TE, \tau_E, E) \) which is the horizontal subbundle, denoted by \( (HE, \tau_H, E) \). Consequently, we can prove that in a v-bundle \( \mathcal{E} \) a N-connection can be introduced as a distribution
\[ \{ N : E_u \rightarrow H_uE, T_uE = H_uE \oplus V_uE \} \]
for every point \( u \in E \) defining a global decomposition, as a Whitney sum, into horizontal, \( H\mathcal{E} \), and vertical, \( V\mathcal{E} \), subbundles of the tangent bundle \( T\mathcal{E} \)
\[ T\mathcal{E} = H\mathcal{E} \oplus V\mathcal{E}. \]
Locally a N-connection in a v–bundle $E$ is given by its coefficients $N^a_i(u) = N^a_i(x,y)$ with respect to bases (2) and (3), $N = N^a_i(u)d^i \otimes \partial_a$. We note that a linear connection in a v–bundle $E$ can be considered as a particular case of a N–connection when $N^a_i(x,y) = K^a_{bi}(x)y^b$, where functions $K^b_{ai}(x)$ on the base $M$ are called the Christoffel coefficients.

2.3.2 N–connections in covector bundles

A nonlinear connection in a cv–bundle $\tilde{E}$ (in brief a $\tilde{N}$–connection) can be introduced in a similar fashion as for v–bundles by reconsidering the corresponding definitions for cv–bundles. For instance, it is stated by a Whitney sum, into horizontal, $H\tilde{E}$, and vertical, $V\tilde{E}$, subbundles of the tangent bundle $T\tilde{E}$:

$$T\tilde{E} = H\tilde{E} \oplus V\tilde{E}.$$  \hspace{1cm} (11)

Hereafter, for the sake of brevity, we shall omit details on definition of geometrical objects on cv–bundles if they are very similar to those for v–bundles: we shall present only the basic formulas by emphasizing the most important common points and differences.

**Definition 2.4.** A $\tilde{N}$–connection on $\tilde{E}$ is a differentiable distribution

$$\tilde{N} : \tilde{E} \to \tilde{N}_u \in T^*_u\tilde{E}$$

which is supplimentary to the vertical distribution $V$, i. e. $T_u\tilde{E} = \tilde{N}_u \oplus \tilde{V}_u, \forall \tilde{E}$.

The same definition is true for $\tilde{N}$–connections in ct–bundles, we have to change in the definition (2.4) the symbol $\tilde{E}$ into $T^*M$.

A N–connection in a cv–bundle $\tilde{E}$ is given locally by its coefficients $\tilde{N}_{ia}(u) = \tilde{N}_{ia}(x,p)$ with respect to bases (2) and (3), $\tilde{N} = \tilde{N}_{ia}(u)d^i \otimes \tilde{\partial}^a$.

We emphasize that if a N–connection is introduced in a v–bundle (cv–bundle), we have to adapt the geometric constructions to the N–connection structure.

2.3.3 N–connections in higher order bundles

The concept of N–connection can be defined for higher order vector / covector bundle in a standard manner like in the usual vector bundles:

**Definition 2.5.** A nonlinear connection $\tilde{N}$ in hvc–bundle $\tilde{E}$ is a splitting of the left of the exact sequence

$$0 \to V\tilde{E} \to T\tilde{E} \to T\tilde{E}/V\tilde{E} \to 0$$  \hspace{1cm} (12)

We can associate sequences of type (12) to every mappings of intermediary subbundles. For simplicity, we present here the Whitney decomposition

$$T\tilde{E} = H\tilde{E} \oplus V_{v(1)}\tilde{E} \oplus V_{v(2)}\tilde{E} \oplus V^*_{cv(3)}\tilde{E} \oplus \ldots \oplus V^*_{cv(z-1)}\tilde{E} \oplus V_{v(z)}\tilde{E}.$$
Locally a $N$–connection $\tilde{N}$ in $\tilde{E}$ is given by its coefficients

\[
\begin{align*}
N_{i}^{a_{1}}, & \quad N_{i}^{a_{2}}, \quad N_{ia_{3}}, \quad \ldots \quad N_{ia_{z-1}}, \quad N_{i}^{a_{z}}, \\
0, & \quad N_{a_{1}}^{a_{2}}, \quad N_{a_{1}a_{3}}, \quad \ldots \quad N_{a_{1}a_{z-1}}, \quad N_{a_{1}}^{a_{z}}, \\
0, & \quad 0, \quad N_{a_{2}a_{3}}, \quad \ldots \quad N_{a_{2}a_{z-1}}, \quad N_{a_{2}}^{a_{z}}, \\
\ldots, & \quad \ldots, \quad 0, \quad \ldots \quad \ldots, \quad \ldots, \\
0, & \quad 0, \quad 0, \quad \ldots \quad N_{a_{z-2}}^{a_{z-1}}, \quad N_{a_{z-1}}^{a_{z}}, \\
0, & \quad 0, \quad 0, \quad \ldots \quad 0, \quad N_{a_{z-1}}^{a_{z}}.
\end{align*}
\] (13)

which are given with respect to the components of bases $[\tilde{B}]$ and $[\tilde{G}]$.

2.3.4 Anholonomic frames and $N$–connections

Having defined a $N$–connection structure in a (vector, covector, or higher order vector / covector) bundle, we can adapt with respect to this structure (by ‘$N$–elongation’) the operators of partial derivatives and differentials and to consider decompositions of geometrical objects with respect to adapted bases and cobases.

**Anholonomic frames in $v$–bundles** In a $v$–bundle $\mathcal{E}$ provided with a $N$–connection we can adapt to this structure the geometric constructions by introducing locally adapted basis ($N$–frame, or $N$–basis):

\[
\delta_{\alpha} = \frac{\delta}{\delta u^{\alpha}} = \left( \delta_{i} = \frac{\delta}{\delta x^{i}} = \partial_{i} - N_{i}^{a} (u) \partial_{a}, \partial_{a} = \frac{\partial}{\partial y^{a}} \right),
\] (14)

and its dual $N$–basis, ($N$–coframe, or $N$–cobasis),

\[
\delta^{\alpha} = \delta u^{\alpha} = \left( d^{i} = \delta x^{i} = dx^{i}, \delta^{a} = \delta y^{a} + N_{i}^{a} (u) dx^{i} \right).
\] (15)

The **anholonomic coefficients**, $w = \{ w_{\beta\gamma}^{a} (u) \}$, of $N$–frames are defined to satisfy the relations

\[
[\delta_{\alpha}, \delta_{\beta}] = \delta_{\alpha} \delta_{\beta} - \delta_{\beta} \delta_{\alpha} = w_{\beta\gamma}^{a} (u) \delta_{\alpha}.
\] (16)

A frame bases is holonomic if all anholonomy coefficients vanish (like for usual coordinate bases $[\mathcal{B}]$), or anholonomic if there are nonzero values of $w_{\beta\gamma}^{a}$.

The operators (14) and (15) on a $v$–bundle $\mathcal{E}$ enabled with a $N$–connection can be considered as respective equivalents of the operators of partial derivations and differentials: the existence of a $N$–connection structure results in ‘elongation’ of partial derivations on $x$–variables and in ‘elongation’ of differentials on $y$–variables.

The algebra of tensorial distinguished fields $DT(\mathcal{E})$ ($d$–fields, $d$–tensors, $d$–objects) on $\mathcal{E}$ is introduced as the tensor algebra $T = \{ T_{qs}^{pr} \}$ of the $v$–bundle $\mathcal{E}_{(d)} = (H\mathcal{E} \oplus \mathcal{V}\mathcal{E}, p_{d}, \mathcal{E})$, where $p_{d} : H\mathcal{E} \oplus \mathcal{V}\mathcal{E} \to \mathcal{E}$.

**Anholonomic frames in $cv$–bundles** The anholonomic frames adapted to the $\tilde{N}$–connection structure are introduced similarly to (14) and (15):

the locally adapted basis ($\tilde{N}$–basis, or $\tilde{N}$–frame):

\[
\tilde{\delta}_{\alpha} = \frac{\tilde{\delta}}{\tilde{\delta} u^{\alpha}} = \left( \tilde{\delta}_{i} = \frac{\tilde{\delta}}{\tilde{\delta} x^{i}} = \partial_{i} + \tilde{N}_{ia} (\tilde{u}) \tilde{\partial}^{a}, \tilde{\partial}^{a} = \frac{\partial}{\partial p_{a}} \right),
\] (17)
where relations on \(\mathcal{F}(\tilde{\mathcal{E}})\), on \(\mathcal{F}(\mathcal{E})\), on \(\mathcal{F}(\mathcal{E})\), on \(\mathcal{F}(\mathcal{E})\) are introduced as the tensor algebra \(\tilde{\mathcal{E}}\) for the module of d–vector fields on \(\mathcal{E}\) or \(\mathcal{M}\) and the set of real functions on \(\mathcal{E}\) or \(\mathcal{M}\).}

\[\tilde{\mathcal{E}} = \tilde{\mathcal{E}}_{pq} := \tilde{\mathcal{E}}_{pq}, \tilde{\mathcal{E}}_{pq} = \tilde{\mathcal{E}}_{pq} \quad \text{or} \quad (\Lambda^p(\mathcal{E})) \quad \text{or} \quad (\Lambda^p(\mathcal{M})) \quad \text{and} \quad \mathcal{F}(\tilde{\mathcal{E}}) \quad \text{or} \quad \mathcal{F}(\mathcal{M}) \quad \text{for the module of d–vector fields on \(\mathcal{E}\) or \(\mathcal{M}\), the exterior algebra of p–forms on \(\mathcal{E}\) or \(\mathcal{M}\) and the set of real functions on \(\mathcal{E}\) or \(\mathcal{M}\).}

**Anholonomic frames in hv–bundles** The anholonomic frames adapted to a \(N\)–connection in hv–bundle \(\mathcal{E}\) are defined by the set of coefficients \([13]\); having restricted the constructions to a vector (covector) shell we obtain some generalizations of the formulas for corresponding \(N\)–connection elongation of partial derivatives defined by \([14]\) or \([17]\) and \([15]\) or \([18]\).

We introduce the adapted partial derivatives (anholonomic N–frames, or N–bases) in \(\tilde{\mathcal{E}}\) by applying the coefficients \([13]\):

\[\tilde{\delta}_\alpha = \frac{\tilde{\delta}}{\tilde{\delta}u^\alpha} = \left(\delta_1, \delta_{a_1}, \tilde{\delta}_{a_2}, ..., \tilde{\delta}_{a_{z-1}}, \delta_{a_z}\right),\]

where

\[\delta_1 = \partial_1 - N^1_{a_1} \partial_{a_1} - N^1_{a_2} \partial_{a_2} + N^1_{a_3} \tilde{\delta}_{a_3} - ... + N^1_{a_{z-1}} \tilde{\delta}_{a_{z-1}} - N^1_{a_z} \partial_{a_z},\]

\[\delta_{a_1} = \partial_{a_1} - N_{a_1}^{a_2} \partial_{a_2} + N_{a_1}^{a_3} \tilde{\delta}_{a_3} - ... + N_{a_1}^{a_{z-1}} \tilde{\delta}_{a_{z-1}} - N_{a_1}^{a_z} \partial_{a_z},\]

\[\delta_{a_2} = \partial_{a_2} + N_{a_2}^{a_3} \tilde{\delta}_{a_3} - ... + N_{a_2}^{a_{z-1}} \tilde{\delta}_{a_{z-1}} - N_{a_2}^{a_z} \partial_{a_z},\]

\[\tilde{\delta}_{a_3} = \tilde{\delta}_{a_3} - N_{a_3}^{a_4} \partial_{a_4} - ... + N_{a_3}^{a_{z-1}} \tilde{\delta}_{a_{z-1}} - N_{a_3}^{a_z} \partial_{a_z},\]

\[\tilde{\delta}_{a_{z-1}} = \tilde{\delta}_{a_{z-1}} - N^{a_{z-1}a_z} \partial_{a_z},\]

\[\partial_{a_z} = \partial/\partial y^{a_z}.\]
These formulas can be written in the matrix form:

\[ \tilde{\delta}_\epsilon = \tilde{N}(u) \times \tilde{\delta}_\epsilon \]  

(20)

where

\[
\tilde{\delta}_\epsilon = \left( \begin{array}{c}
\tilde{\delta}_1 \\
\tilde{\delta}_{\alpha_1} \\
\tilde{\delta}_{\alpha_2} \\
\vdots \\
\tilde{\delta}_{\alpha_{z-1}} \\
\partial_{\alpha_z}
\end{array} \right), \quad \tilde{\delta}_\epsilon = \left( \begin{array}{c}
\tilde{\delta}_1 \\
\tilde{\delta}_{\alpha_1} \\
\tilde{\delta}_{\alpha_2} \\
\vdots \\
\tilde{\delta}_{\alpha_{z-1}} \\
\partial_{\alpha_z}
\end{array} \right),
\]

and

\[
\tilde{N} = \left( \begin{array}{cccccccc}
1 & -N_i^{a_1} & -N_i^{a_2} & N_i^{a_3} & -N_i^{a_4} & \ldots & N_i^{a_{z-1}} & -N_i^{a_z} \\
0 & 1 & -N_{a_1}^{a_2} & N_{a_1}^{a_3} & -N_{a_1}^{a_4} & \ldots & N_{a_1}^{a_{z-1}} & -N_{a_1}^{a_z} \\
0 & 0 & 1 & -N_{a_2}^{a_3} & N_{a_2}^{a_4} & \ldots & N_{a_2}^{a_{z-1}} & -N_{a_2}^{a_z} \\
0 & 0 & 0 & 1 & -N_{a_3}^{a_4} & \ldots & N_{a_3}^{a_{z-1}} & -N_{a_3}^{a_z} \\
0 & 0 & 0 & 0 & 0 & \ldots & 1 & -N^{a_{z-1}a_z} \\
0 & 0 & 0 & 0 & 0 & \ldots & 0 & 1
\end{array} \right).
\]

The adapted differentials (anholonomic N–coframes, or N–cobases) in \( \tilde{\mathcal{E}} \) are introduced in the simplest form by using the matrix formalism: The respective dual matrices

\[
\tilde{\delta}^\alpha = \{\tilde{\delta}^\alpha\} = (d^i \delta^{a_1} \delta^{a_2} \delta^{a_3} \ldots \delta^{a_{z-1}} \delta^{a_z}) ,
\]

\[
d^\alpha = \{d^\alpha\} = (d^i d^{a_1} d^{a_2} d^{a_3} \ldots d^{a_{z-1}} d^{a_z})
\]

are related via a matrix relation

\[ \tilde{\delta}^\alpha = d^\alpha \tilde{M} \]  

(21)

which defines the formulas for anholonomic N–coframes. The matrix \( \tilde{M} \) from (21) is the inverse to \( \tilde{N} \), i. e. satisfies the condition

\[ \tilde{M} \times \tilde{N} = I. \]  

(22)

The anholonomic coefficients, \( \tilde{w} = \{\tilde{w}_{\beta^\gamma}^\alpha(\tilde{u})\} \), on hcv–bundle \( \tilde{\mathcal{E}} \) are expressed via coefficients of the matrix \( \tilde{N} \) and their partial derivatives following the relations

\[ [\tilde{\delta}_\alpha, \tilde{\delta}_\beta] = \delta_\alpha \delta_\beta - \delta_\beta \delta_\alpha = \tilde{w}_{\beta^\gamma}^\alpha(\tilde{u}) \tilde{\delta}_\alpha. \]  

(23)

We omit the explicit formulas on shells.

A d–tensor formalism can be also developed on the space \( \tilde{\mathcal{E}} \). In this case the indices have to be stipulated for every shell separately, like for v–bundles or cv–bundles.
In general, distinguished objects (d–objects) on a v–bundle $\mathcal{E}$ (or cv–bundle $\tilde{\mathcal{E}}$) are introduced as geometric objects with various group and coordinate transforms coordinated with the N–connection structure on $\mathcal{E}$ (or $\tilde{\mathcal{E}}$). For example, a distinguished connection (in brief, d–connection) $D$ on $\mathcal{E}$ (or $\tilde{\mathcal{E}}$) is defined as a linear connection $D$ on $E$ (or $\tilde{E}$) conserving under a parallelism the global decomposition (10) (or (11)) into horizontal and vertical subbundles of $TE$ (or $T\tilde{E}$). A covariant derivation associated to a d–connection becomes d–covariant. We shall give necessary formulas for cv–bundles in round brackets.

3.1 D–connections

3.1.1 D–connections in v–bundles (cv–bundles)

A N–connection in a v–bundle $\mathcal{E}$ (cv–bundle $\tilde{\mathcal{E}}$) induces a corresponding decomposition of d–tensors into sums of horizontal and vertical parts, for example, for every d–vector $X \in \mathcal{X} (\mathcal{E}) (\tilde{X} \in \mathcal{X} (\tilde{\mathcal{E}}))$ and 1–form $A \in \Lambda^1 (\mathcal{E}) (\tilde{A} \in \Lambda^1 (\tilde{\mathcal{E}}))$ we have respectively

$$X = hX + vX \quad \text{and} \quad A = hA + vA, \quad (24)$$

where

$$hX = X^i \delta_i, \quad vX = X^a \partial_a \quad (h\tilde{X} = \tilde{X}^i \tilde{\delta}_i, \quad v\tilde{X} = \tilde{X}^a \tilde{\partial}_a)$$

and

$$hA = A_i \delta^i, \quad vA = A_a \partial^a \quad (h\tilde{A} = \tilde{A}^i \tilde{\partial}^i, \quad v\tilde{A} = \tilde{A}^a \tilde{\partial}^a).$$

In consequence, we can associate to every d–covariant derivation along the d–vector (24), $D_X = X \circ D$ ($D_{\tilde{X}} = \tilde{X} \circ D$) two new operators of h- and v–covariant derivations

$$D_X^{(h)} Y = D_{hX} Y \quad \text{and} \quad D_X^{(v)} Y = D_{vX} Y, \quad \forall Y \in \mathcal{X} (\mathcal{E})$$

$$D_{\tilde{X}}^{(h)} \tilde{Y} = D_{h\tilde{X}} \tilde{Y} \quad \text{and} \quad D_{\tilde{X}}^{(v)} \tilde{Y} = D_{v\tilde{X}} \tilde{Y}, \quad \forall \tilde{Y} \in \mathcal{X} (\tilde{\mathcal{E}})$$

for which the following conditions hold:

$$D_X Y = D_X^{(h)} Y + D_X^{(v)} Y \quad (25)$$

$$D_{\tilde{X}} \tilde{Y} = D_{\tilde{X}}^{(h)} \tilde{Y} + D_{\tilde{X}}^{(v)} \tilde{Y},$$

where

$$D_X^{(h)} f = (hX) f \quad \text{and} \quad D_X^{(v)} f = (vX) f, \quad X, Y \in \mathcal{X} (\mathcal{E}), \quad f \in \mathcal{F} (M)$$

$$D_{\tilde{X}}^{(h)} \tilde{f} = (h\tilde{X}) \tilde{f} \quad \text{and} \quad D_{\tilde{X}}^{(v)} \tilde{f} = (v\tilde{X}) \tilde{f}, \quad \tilde{X}, \tilde{Y} \in \mathcal{X} (\tilde{\mathcal{E}}), \quad f \in \mathcal{F} (M).$$

The components $\Gamma^a_{\beta\gamma}$ (or $\tilde{\Gamma}^a_{\beta\gamma}$) of a d–connection $\tilde{D}_a = (\tilde{\delta}_a \circ D)$, locally adapted to the N—connection structure with respect to the frames (14) and (15) (17) and (18), are defined by the equations

$$D_\alpha \delta_\beta = \Gamma^\gamma_{\alpha\beta} \delta_\gamma \quad (\tilde{D}_\alpha \tilde{\delta}_\beta = \tilde{\Gamma}^\gamma_{\alpha\beta} \tilde{\delta}_\gamma).$$
from which one immediately follows
\[
\Gamma^\gamma_{\alpha\beta}(u) = (D_\alpha \delta_\beta) \circ \delta^\gamma \quad (\tilde{\Gamma}^\gamma_{\alpha\beta} (\tilde{u}) = \left( \tilde{D}_\alpha \tilde{\delta}_\beta \right) \circ \tilde{\delta}^\gamma). \tag{26}
\]

The coefficients of operators of h- and v-covariant derivations,
\[
D^h_k = \{ L^i_{jk}, L^a_{bk} \} \quad \text{and} \quad D^{(v)}_c = \{ C^i_{jk}, C^a_{bc} \}
\]
\[
(\tilde{D}^h_k) = \{ \tilde{L}^i_{jk}, \tilde{L}^{\tilde{b}}_{ak} \} \quad \text{and} \quad (\tilde{D}^{(v)}_c) = \{ \tilde{C}^{\tilde{i}}_{\tilde{j}k}, \tilde{C}^{\tilde{a}}_{\tilde{b}c} \}
\]
(see \[26\]), are introduced as corresponding h- and v-parametrizations of \[26\]
\[
L^i_{jk} = (D_k \delta_j) \circ d^i, \quad L^a_{bk} = (D_k \delta_b) \circ d^a \tag{27}
\]
\[
(\tilde{L}^i_{jk}) = (\tilde{D}_k \tilde{\delta}_j) \circ d^i, \quad \tilde{L}^{\tilde{b}}_{ak} = (\tilde{D}_k \tilde{\delta}^\tilde{b}) \circ \tilde{\delta}_a \tag{28}
\]
and
\[
C^i_{jc} = (D_c \delta_j) \circ d^i, \quad C^a_{bc} = (D_c \delta_b) \circ d^a
\]
\[
(\tilde{C}^{\tilde{i}}_{\tilde{j}c}) = (\tilde{D}^{\tilde{c}}_{\tilde{j}} \tilde{\delta}^\tilde{i}) \circ d^\tilde{i}, \quad \tilde{C}^{\tilde{a}}_{\tilde{b}c} = (\tilde{D}^{\tilde{c}}_{\tilde{b}} \tilde{\delta}^\tilde{a}) \circ \tilde{\delta}_a.
\]
A set of components \[27\] and \[28\]
\[
\Gamma^\gamma_{\alpha\beta} = [L^i_{jk}, L^a_{bk}; C^i_{jc}, C^a_{bc}] \quad (\tilde{\Gamma}^\gamma_{\alpha\beta} = [\tilde{L}^i_{jk}, \tilde{L}^{\tilde{b}}_{ak}; \tilde{C}^{\tilde{i}}_{\tilde{j}c}, \tilde{C}^{\tilde{a}}_{\tilde{b}c}])
\]
completely defines the local action of a d—connection \( D \) in \( \mathcal{E} \) (\( \tilde{D} \) in \( \tilde{\mathcal{E}} \)).

For instance, having taken on \( \mathcal{E} \) (\( \tilde{\mathcal{E}} \)) a d—tensor field of type \( \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \),
\[
t = t_{ja}^i \partial_t \otimes \partial_\alpha \otimes d^i \otimes \tilde{\delta}_b, \quad \tilde{t} = \tilde{t}_{ja}^i \partial_t \otimes \tilde{\partial}_a \otimes d^i \otimes \tilde{\delta}_b,
\]
and a d—vector \( X \) (\( \tilde{X} \)) we obtain
\[
D_X t = D_X^{(h)} t + D_X^{(v)} t = \left( X^k \tilde{t}_{jb}^a + X^c \tilde{t}_{jbc}^a \right) \delta_i \otimes \partial_\alpha \otimes d^i \otimes \tilde{\delta}_b,
\]
\[
(\tilde{D}_X \tilde{t}) = (\tilde{D}^{\tilde{h}}_X \tilde{t}) + (\tilde{D}^{\tilde{v}}_X \tilde{t}) = \left( \tilde{X}^k \tilde{t}_{ja}^b + \tilde{X}^c \tilde{t}_{jbc}^b \right) \tilde{\delta}_i \otimes \tilde{\partial}_a \otimes d^i \otimes \tilde{\delta}_b
\]
where the h—covariant derivative is written
\[
t_{ja}^i = \partial t_{ja}^i + C^i_{ja} \delta_a^b + C^a_{ja} \delta^i + C^a_{ja} \delta^i - C^a_{ja} \delta^i + C^a_{ja} \delta^i
\]
\[
(\tilde{t}_{ja}^i) = \partial \tilde{t}_{ja}^i + \tilde{C}^{\tilde{i}}_{\tilde{j}a} \tilde{\delta}_b + \tilde{C}^{\tilde{a}}_{\tilde{j}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{j}a} \tilde{\delta}^\tilde{i} - \tilde{C}^{\tilde{a}}_{\tilde{j}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{j}a} \tilde{\delta}^\tilde{i}
\]
and the v-covariant derivative is written
\[
(\tilde{t}_{ja}^i) = \partial \tilde{t}_{ja}^i + \tilde{C}^{\tilde{i}}_{\tilde{j}a} \tilde{\delta}_b + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} - \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i}
\]
\[
(\tilde{t}_{ja}^i) = \partial \tilde{t}_{ja}^i + \tilde{C}^{\tilde{i}}_{\tilde{j}a} \tilde{\delta}_b + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} - \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i}
\]
\[
(\tilde{t}_{ja}^i) = \partial \tilde{t}_{ja}^i + \tilde{C}^{\tilde{i}}_{\tilde{j}a} \tilde{\delta}_b + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} - \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i} + \tilde{C}^{\tilde{a}}_{\tilde{i}a} \tilde{\delta}^\tilde{i}
\]
For a scalar function \( f \in \mathcal{F}(\mathcal{E}) \) (\( f \in \mathcal{F}(\tilde{\mathcal{E}}) \)) we have
\[
D^{(h)}_k = \frac{\partial f}{\partial x^k} = \frac{\partial f}{\partial x^k} - N_k^a \frac{\partial f}{\partial y^a} \quad \text{and} \quad D^{(v)}_c f = \frac{\partial f}{\partial y^c}
\]
\[
(\tilde{D}^{(h)}_k) = \frac{\partial f}{\partial x^k} + N_k^a \frac{\partial f}{\partial p_a} \quad \text{and} \quad (\tilde{D}^{(v)}_c) f = \frac{\partial f}{\partial p_c}.
\]
3.1.2 D–connections in hvc–bundles

The theory of connections in higher order anisotropic vector superbundles and vector bundles was elaborated in Refs. [12, 41, 43]. Here we re–formulate that formalism for the case when some shells of higher order anisotropy could be covector spaces by stating the general rules of covariant derivation compatible with the N–connection structure in hvc–bundle \( \tilde{E} \) and omit details and cumbersome formulas.

For a hvc–bundle of type \( \tilde{E} = \tilde{E}[v(1), v(2), cv(3), ..., cv(z - 1), v(z)] \) a d–connection \( \tilde{\Gamma}^\gamma_{\alpha \beta} \) has the next shell decomposition of components (on induction being on the \( p \)-th shell, considered as the base space, which in this case a hvc–bundle, we introduce in a usual manner, like a vector or covector fiber, the \( (p + 1) \)-th shell)

\[
\tilde{\Gamma}^\gamma_{\alpha \beta} = \{ \Gamma^{\gamma_1}_{\alpha_1 \beta_1} = [L^{i_1}_{j_1 k_1}, L^{a_1}_{b_1 c_1}, C^{a_1}_{\beta_1 c_1}], \Gamma^{\gamma_2}_{\alpha_2 \beta_2} = [L^{i_2}_{j_2 k_2}, L^{a_2}_{b_2 c_2}, C^{a_2}_{\beta_2 c_2}], \}
\]

\[
\tilde{\Gamma}^{\gamma_{z-1}}_{\alpha_{z-1} \beta_{z-1}} = [\tilde{L}^{i_{z-1}}_{j_{z-1} k_{z-1}}, \tilde{L}^{b_{z-1}}_{a_{z-1} c_{z-1}}, \tilde{C}^{a_{z-1}}_{\beta_{z-1} c_{z-1}}, \], \Gamma^{\gamma_z}_{\alpha_z \beta_z} = [L^{i_z}_{j_z k_z}, L^{a_z}_{b_z c_z}, C^{a_z}_{\beta_z c_z}], \}
\]

These coefficients determine the rules of a covariant derivation \( \tilde{D} \) on \( \tilde{E} \).

For example, let us consider a d–tensor \( \tilde{t} \) of type \( \frac{1}{1 1 1 2 1 2 1 3 1 4 1 5 1 6} \) with corresponding tensor product of components of anholonomic N–frames (20) and (21)

\[
\tilde{t} = \tilde{t}^{a_1 a_2 b_1 b_2 a_3 a_4 a_5 a_6} \delta_1 \otimes \partial_{a_1} \otimes d^1 \otimes \delta^{b_1} \otimes \partial_{a_2} \otimes \delta^{b_2} \otimes \tilde{\partial}^{c_1} \otimes \tilde{\partial}^{c_2} \otimes \tilde{\partial}^{a_{z-1}} \otimes \tilde{\partial}^{b_{z-1}} \otimes \partial_{a_z} \otimes \delta^{b_z}.
\]

The d–covariant derivation \( \tilde{D} \) of \( \tilde{t} \) is to be performed separately for every shell according the rule (29) if a shell is defined by a vector subspace, or according the rule (30) if the shell is defined by a covector subspace.

3.2 Metric structure

3.2.1 D–metrics in v–bundles

We define a metric structure \( G \) in the total space \( E \) of a v–bundle \( E = (E, p, M) \) over a connected and paracompact base \( M \) as a symmetric covariant tensor field of type \( (0, 2) \),

\[
G = G_{\alpha \beta} du^\alpha \otimes du^\beta
\]

being non degenerate and of constant signature on \( E \).

Nonlinear connection \( N \) and metric \( G \) structures on \( E \) are mutually compatible if there are satisfied the conditions:

\[
G(\delta_i, \partial_a) = 0, \text{ or equivalently, } G_{ia}(u) - N^b_i(u) h_{ab}(u) = 0, \quad (31)
\]

where \( h_{ab} = G(\partial_a, \partial_b) \) and \( G_{ia} = G(\partial_i, \partial_a) \), which gives

\[
N^b_i(u) = h^{ab}(u) G_{ia}(u) \quad (32)
\]

( the matrix \( h^{ab} \) is inverse to \( h_{ab} \)). One obtains the following decomposition of metric:

\[
G(X, Y) = hG(X, Y) + vG(X, Y), \quad (33)
\]

15
where the d–tensor $hG(X,Y) = G(hX,hY)$ is of type $\begin{pmatrix} 0 & 0 \\ 2 & 0 \end{pmatrix}$ and the d–tensor $vG(X,Y) = G(vX,vY)$ is of type $\begin{pmatrix} 0 & 0 \\ 0 & 2 \end{pmatrix}$. With respect to the anholonomic basis the d–metric is written

$$G = g_{\alpha\beta}(u) \delta^\alpha \otimes \delta^\beta = g_{ij}(u) \, d^i \otimes d^j + h_{ab}(u) \, \delta^a \otimes \delta^b,$$

where $g_{ij} = G(\delta_i,\delta_j)$.

A metric structure of type (33) (equivalently, of type (34)) or a metric on $E$ with components satisfying the constraints defines an adapted to the given N–connection inner (d–scalar) product on the tangent bundle $\mathcal{T}E$.

A d–connection $D_X$ is metric (or compatible with metric $G$) on $E$ if $D_X G = 0, \forall X \in \mathcal{X}(E)$. With respect to anholonomic frames these conditions are written

$$D_\alpha g_{\beta\gamma} = 0, \quad (35)$$

where by $g_{\beta\gamma}$ we denote the coefficients in the block form (34).

### 3.2.2 D–metrics in cv– and hvc–bundles

The presented considerations on self–consistent definition of N–connection, d–connection and metric structures in v–bundles can re–formulated in a similar fashion for another types of anisotropic space–times, on cv–bundles and on shells of hvc–bundles. For simplicity, we give here only the analogous formulas for the metric d–tensor (34):

- **On cv–bundle $\mathcal{E}$** we write
  $$\tilde{G} = \tilde{g}_{\alpha\beta}(\tilde{u}) \tilde{\delta}^\alpha \otimes \tilde{\delta}^\beta = \tilde{g}_{ij}(\tilde{u}) \, d^i \otimes d^j + \tilde{h}^{ab}(\tilde{u}) \, \tilde{\delta}^a \otimes \tilde{\delta}^b,$$

  where $\tilde{g}_{ij} = \tilde{G}(\tilde{\delta}_i,\tilde{\delta}_j)$ and $\tilde{h}^{ab} = \tilde{G}(\tilde{\delta}^a,\tilde{\delta}^b)$ and the N–coframes are given by formulas (18).

  For simplicity, we shall consider that the metricity conditions are satisfied, $\tilde{D}_\gamma \tilde{g}_{\alpha\beta} = 0$.

- **On hvc–bundle $\mathcal{E}$** we write
  $$\mathcal{G} = \tilde{g}_{\alpha\beta}(\tilde{u}) \tilde{\delta}^\alpha \otimes \tilde{\delta}^\beta = \tilde{g}_{ij}(\tilde{u}) \, d^i \otimes d^j + \tilde{h}_{a_1b_1}(\tilde{u}) \, \tilde{\delta}^{a_1} \otimes \tilde{\delta}^{b_1} + \tilde{h}_{a_2b_2}(\tilde{u}) \, \tilde{\delta}^{a_2} \otimes \tilde{\delta}^{b_2},$$

  where $\tilde{g}_{ij} = \tilde{G}(\tilde{\delta}_i,\tilde{\delta}_j)$ and $\tilde{h}_{a_1b_1} = \tilde{G}(\partial_{a_1},\partial_{b_1}), \tilde{h}_{a_2b_2} = \tilde{G}(\partial_{a_2},\partial_{b_2}),$

  $\tilde{h}_{a_3b_3} = \tilde{G}(\tilde{\delta}^{a_3},\tilde{\delta}^{b_3}), \ldots$ and the N–coframes are given by formulas (21).

  The metricity conditions are $\tilde{D}_\gamma \tilde{g}_{\alpha\beta} = 0$.

- **On osculator bundle $T^2M = Osc^2M$**, we have a particular case of (37) when

  $$\mathcal{G} = \tilde{g}_{\alpha\beta}(\tilde{u}) \tilde{\delta}^\alpha \otimes \tilde{\delta}^\beta = \tilde{g}_{ij}(\tilde{u}) \, d^i \otimes d^j + \tilde{h}_{ij}(\tilde{u}) \, \delta y^i_{(1)} \otimes \delta y^i_{(1)} + \tilde{h}_{ij}(\tilde{u}) \, \delta y^i_{(2)} \otimes \delta y^i_{(2)},$$

  with respect to N–coframes.
On dual osculator bundle \((T^* M, p^2, M)\) we have another particular case of (37) when
\[
\tilde{G} = \tilde{g}_{\alpha \beta}(\tilde{u}) \delta^\alpha \otimes \delta^\beta
\]
\[
= \tilde{g}_{ij}(\tilde{u}) d^i \otimes d^j + \tilde{h}_{ij}(\tilde{u}) \delta y^i_{(1)} \otimes \delta y^j_{(1)} + \tilde{h}^{ij}(\tilde{u}) \delta p^i_{(2)} \otimes \delta p^j_{(2)}
\]
with respect to N–coframes.

3.3 Some examples of d–connections

We emphasize that the geometry of connections in a v–bundle \(E\) is very rich. If a triple of
fundamental geometric objects \((N^a_i (u), \Gamma^\alpha_{\beta \gamma}(u), g_{\alpha \beta}(u))\) is fixed on \(E\), a multi–connection
structure (with corresponding different rules of covariant derivation, which are, or not,
mutually compatible and with the same, or not, induced d–scalar products in \(TE\)) is defined
on this v–bundle. We can give a priority to a connection structure following some physical
arguments, like the reduction to the Christoffel symbols in the holonomic case, mutual
compatibility between metric and N–connection and d–connection structures and so on.

In this subsection we enumerate some of the connections and covariant derivations in v–
bundle \(E\), cv–bundle \(\check{E}\) and in some hvc–bundles which can present interest in investigation
of locally anisotropic gravitational and matter field interactions :

1. Every N–connection in \(E\) with coefficients \(N^a_i (x,y)\) being differentiable on y–variables,
induces a structure of linear connection \(N^\alpha_{\beta \gamma}\), where
\[
N^a_{bi} = \frac{\partial N^a_i}{\partial y^b} \text{ and } N^a_{bc}(x,y) = 0.
\]
For some \(Y(u) = Y^i(u) \partial_i + Y^a(u) \partial_a\) and \(B(u) = B^a(u) \partial_a\) one introduces a covariant
derivation as
\[
D_Y^b N_B = \left[ Y^i \left( \frac{\partial B^a}{\partial x^i} + N^a_{bi} B^b \right) + Y^b \frac{\partial B^a}{\partial y^b} \right] \frac{\partial}{\partial y^a}.
\]

2. The d–connection of Berwald type on v–bundle \(E\) (cv–bundle \(\check{E}\))
\[
\Gamma^{(B)\alpha}_{\beta \gamma} = \left( L^i_{jk}, \frac{\partial N^a_k}{\partial y^b}, 0, C^{a}_{bc} \right),
\]
\[
(\check{\Gamma}^{(B)\alpha}_{\beta \gamma} = \left( \check{L}^i_{jk}, -\frac{\partial \check{N}^p_k}{\partial p_b}, 0, \check{C}^{p}_{a bc} \right))
\]
where
\[
L^i_{jk} (x,y) = \frac{1}{2} g^{ir} \left( \delta g_{jk} + \delta g_{kr} - \delta g_{jr} \right),
\]
\[
C^{a}_{bc} (x,y) = \frac{1}{2} h^{ad} \left( \delta h_{bd} + \delta h_{cd} - \delta h_{bd} \right),
\]
\[
(\check{L}^i_{jk} (x,p) = \frac{1}{2} \check{g}^{ir} \left( \delta \check{g}_{jk} + \delta \check{g}_{kr} - \delta \check{g}_{jr} \right),
\]
\[
(\check{C}^{p}_{a bc} (x,p) = \frac{1}{2} \check{h}^{ad} \left( \delta \check{h}_{bd} + \delta \check{h}_{cd} - \delta \check{h}_{bd} \right).
\]
which is hv—metric, i.e. there are satisfied the conditions \( D_k^{(B)} g_{ij} = 0 \) and \( D_c^{(B)} h_{ab} = 0 \) 
\( (\tilde{D}_k^{(B)} g_{ij} = 0 \) and \( \tilde{D}^{(B)c} \tilde{h}^{ab} = 0 \).

3. The canonical d–connection \( \Gamma^{(e)} \) (or \( \tilde{\Gamma}^{(e)} \)) on a v–bundle (or cv–bundle) is associated to a metric \( G \) (or \( \tilde{G} \)) of type (32) (or (30)),
\[
\Gamma^{(e)\alpha}_{\beta\gamma} = [L_{jk}^{(c)i}, L_{bk}^{(c)a}, C_{jc}^{(c)a}, C_{bc}^{(c)a}] 
\tilde{\Gamma}^{(e)\alpha}_{\beta\gamma} = [\tilde{L}_{jk}^{(c)i}, \tilde{L}_{a.k}^{(c)b}, \tilde{C}_{jc}^{(c)i}, c, \tilde{C}_{a}^{(c)bc}] 
\]
with coefficients
\[
L_{jk}^{(c)i} = L_{jk}^{i}, C_{bc}^{(c)a} = C_{bc}^{a} (\tilde{L}_{jk}^{(c)i} = \tilde{L}_{jk}^{i}, \tilde{C}_{a}^{(c)bc} = \tilde{C}_{a}^{bc}), \text{ (see (42))} 
\]
\[
\begin{align*}
L_{bi}^{(c)a} &= \frac{\partial N_{i}^{a}}{\partial y^{b}} + \frac{1}{2} h^{ac} \left( \frac{\partial h_{bc}}{\partial x^{a}} - \frac{\partial N_{d}^{c}}{\partial y^{b}} h_{dc} - \frac{\partial N_{i}^{d}}{\partial y^{c}} h_{db} \right) \\
(\tilde{L}_{a.j}^{(c)b}) &= \frac{\partial \tilde{N}_{i}^{a}}{\partial p_{b}} + \frac{1}{2} \tilde{h}_{ac} \left( \frac{\partial \tilde{h}_{bc}}{\partial x^{a}} + \frac{\partial \tilde{N}_{id}^{c}}{\partial p_{b}} \tilde{h}_{dc} + \frac{\partial \tilde{N}_{id}^{d}}{\partial p_{c}} \tilde{h}_{db} \right), \\
C_{jc}^{(c)i} &= \frac{1}{2} g^{ik} \frac{\partial g_{jk}}{\partial y^{c}} (\tilde{C}_{jc}^{(c)i} = \frac{1}{2} g^{ik} \frac{\partial \tilde{g}_{jk}}{\partial p_{c}}). \tag{43} 
\end{align*}
\]
This is a metric d–connection which satisfies conditions
\[
\begin{align*}
D_{k}^{(c)} g_{ij} &= 0, D_{c}^{(c)} g_{ij} = 0, D_{k}^{(c)} h_{ab} = 0, D_{c}^{(c)} h_{ab} = 0 \\
(\tilde{D}_{k}^{(c)} g_{jk} &= 0, \tilde{D}_{c}^{(c)} g_{jk} = 0, \tilde{D}_{k}^{(c)} \tilde{h}^{bc} = 0, \tilde{D}_{c}^{(c)} \tilde{h}^{ab} = 0). 
\end{align*}
\]
In physical applications, we shall use the canonical connection and, for simplicity, we shall omit the index \((c)\). The coefficients (43) are to be extended to higher order if we are dealing with derivations of geometrical objects with “shell” indices. In this case the fiber indices are to be stipulated for every type of shell into consideration.

4. We can consider the N–adapted Christoffel symbols
\[
\bar{\Gamma}_{\beta\gamma}^{\alpha} = \frac{1}{2} g^{\alpha\tau} \left( \delta_{\gamma} g_{\tau\beta} + \delta_{\beta} g_{\tau\gamma} - \delta_{\gamma} g_{\beta\tau} \right), \tag{42} 
\]
which have the components of d–connection \( \bar{\Gamma}_{\beta\gamma}^{\alpha} = (L_{jk}^{i}, 0, 0, C_{bc}^{a}) \), with \( L_{jk}^{i} \) and \( C_{bc}^{a} \) as in (42) if \( g_{\alpha\beta} \) is taken in the form (34).

### 3.4 Almost Hermitian anisotropic spaces

The are possible very interesting particular constructions on t–bundle \( TM \) provided with N–connection which defines a N–adapted frame structure \( \delta_{a} = (\delta_{i}, \hat{\delta}_{i}) \) (for the same formulas and but with identified fiber and base indices). We are using the ‘dot’ symbol in order to distinguish the horizontal and vertical operators because on t–bundles the indices could take the same values both for the base and fiber objects. This allow us to define an almost complex structure \( J = \{ J_{\alpha}^{\beta} \} \) on \( TM \) as follows
\[
J(\delta_{i}) = -\hat{\delta}_{i}, \ J(\hat{\delta}_{i}) = \delta_{i}. \tag{45} 
\]
It is obvious that $J$ is well-defined and $J^2 = -I$.

For $d$–metrics of type (34), on $TM$, we can consider the case when $g_{ij}(x,y) = h_{ab}(x,y)$, i.e.

$$G_{(t)} = g_{ij}(x,y)dx^i \otimes dx^j + g_{ij}(x,y)\delta y^i \otimes \delta y^j,$$

where the index $(t)$ denotes that we have geometrical object defined on tangent space.

An almost complex structure $J_{\alpha}^{\beta}$ is compatible with a $d$–metric of type (46) and a $d$–connection $D$ on tangent bundle $TM$ if the conditions

$$J_{\alpha}^{\beta} J_{\gamma}^{\delta} g_{\beta \delta} = g_{\alpha \gamma} \quad \text{and} \quad D_{\alpha} J_{\gamma}^{\beta} = 0$$

are satisfied.

The pair $(G_{(t)}, J)$ is an almost Hermitian structure on $TM$.

One can introduce an almost sympletic 2–form associated to the almost Hermitian structure $(G_{(t)}, J)$,

$$\theta = g_{ij}(x,y)\delta y^i \wedge dx^j.$$ 

(47) If the 2–form (47), defined by the coefficients $g_{ij}$, is closed, we obtain an almost Kählerian structure in $TM$.

**Definition 3.1.** An almost Kähler metric connection is a linear connection $D^{(H)}$ on $T\tilde{M} = TM \setminus \{0\}$ with the properties:

1. $D^{(H)}$ preserve by parallelism the vertical distribution defined by the N–connection structure;
2. $D^{(H)}$ is compatible with the almost Kähler structure $(G_{(t)}, J)$, i.e.

$$D^{(H)}_X g = 0, \quad D^{(H)}_X J = 0, \quad \forall X \in \mathcal{X} \left( T\tilde{M} \right).$$

By straightforward calculation we can prove that a $d$–connection $D\Gamma = (L^i_{jk}, L^i_{jk}, C^i_{jc}, C^i_{jc})$ with the coefficients defined by

$$D^{(H)}_{\delta_i} \delta_j = L^i_{jk} \delta_i, \quad D^{(H)}_{\delta_i} \dot{\delta}_j = L^i_{jk} \dot{\delta}_i, \quad D^{(H)}_{\delta_i} \delta_j = C^i_{jk} \delta_i, \quad D^{(H)}_{\delta_i} \dot{\delta}_j = C^i_{jk} \dot{\delta}_i,$$

(48) where $L^i_{jk}$ and $C^i_{ab} \rightarrow C^i_{jk}$ on $TM$ are defined by the formulas (42), define a torsionless (see the next section on torsion structures) metric $d$–connection which satisfy the compatibility conditions (35).

Almost complex structures and almost Kähler models of Finsler, Lagrange, Hamilton and Cartan geometries (of first an higher orders) are investigated in details in Refs. [22, 43].

### 3.5 Torsions and Curvatures

We outline the basic definitions and formulas for the torsion and curvature structures in v–bundles and cv–bundles provided with N–connection structure.
3.5.1 N–connection curvature

1. The curvature $\Omega$ of a nonlinear connection $N$ in a v–bundle $E$ can be defined in local form as [23]:

$$\Omega = \frac{1}{2} \Omega^a_{ij} d^i \wedge d^j \otimes \partial_a,$$

where

$$\Omega^a_{ij} = \delta_j N^a_i - \delta_i N^a_j = \partial_j N^a_i - \partial_i N^a_j + N^b_i N^a_{bj} - N^b_j N^a_{bi},$$

$N^a_i$ being that from [40].

2. For the curvature $\tilde{\Omega}$, of a nonlinear connection $\tilde{N}$ in a cv–bundle $\tilde{E}$ we introduce

$$\tilde{\Omega} = \frac{1}{2} \tilde{\Omega}^a_{ija} d^i \wedge d^j \otimes \partial^a,$$

where

$$\tilde{\Omega}^a_{ija} = -\delta_j \tilde{N}^a_i + \delta_i \tilde{N}^a_j = -\partial_j \tilde{N}^a_i + \partial_i \tilde{N}^a_j + \tilde{N}^b_i \tilde{N}^a_{ja} b - \tilde{N}^b_j \tilde{N}^a_{ja} b,$$

$$\tilde{N}^a_{ja} b = \partial^b \tilde{N}^a_{ja} = \partial \tilde{N}^a_{ja} / \partial p_b.$$ (50)

3. There were analyzed the curvatures $\tilde{\Omega}$ of different type of nonlinear connections $\tilde{N}$ in higher order anisotropic bundles were analyzed for higher order tangent/dual tangent bundles and higher order prolongations of generalized Finsler, Lagrange and Hamilton spaces in Refs. [23] and for higher order anisotropic superspaces and spinor bundles in Refs. [43, 39, 44, 42]: For every higher order anisotropy shell, we shall define the coefficients (49) or (50) in dependence of the fact with type of subfiber we are considering (a vector or covector fiber).

3.5.2 d–Torsions in v– and cv–bundles

The torsion $T$ of a d–connection $D$ in v–bundle $E$ (cv–bundle $\tilde{E}$) is defined by the equation

$$T (X, Y) = XY^o \circ T = D_X Y - D_Y X - [X, Y].$$ (51)

One holds the following h- and v–decompositions

$$T (X, Y) = T (hX, hY) + T (hX, vY) + T (vX, hY) + T (vX, vY).$$

We consider the projections:

$$hT (X, Y), vT (hX, hY), hT (hX, hY), ...$$

and say that, for instance, $hT (hX, hY)$ is the h(hh)–torsion of $D$, $vT (hX, hY)$ is the v(hh)–torsion of $D$ and so on.

The torsion $\mathcal{T}$ in v–bundle is locally determined by five d–tensor fields, torsions, defined as

$$T^i_{jk} = hT (\delta_k, \delta_j) \cdot d^i, \quad T^a_{jk} = vT (\delta_k, \delta_j) \cdot \delta^a,$$

$$P^a_{jb} = hT (\delta_b, \delta_j) \cdot d^a, \quad P^a_{jb} = vT (\delta_b, \delta_j) \cdot \delta^a, S^a_{bc} = vT (\delta_c, \delta_b) \cdot \delta^a.$$ (52)
Using formulas (14), (15), (49) and (51) we can compute \( T_{jk} \) in explicit form the components of torsions (52) for a d–connection of type (27) and (28):

\[
T_{jk} = T_{j} = L_{jk} - L_{kj}, \quad T_{ja} = C_{ji}a, \quad T_{ja} = -C_{ja}, \quad T_{ja} = 0, \quad T_{jb} = -P_{ba} \tag{53}
\]

Formulas similar to (52) and (53) hold for cv–bundles:

\[
\begin{align*}
\tilde{T}_{jk} &= hT(\delta_{k}, \delta_{j}) \cdot d^i, \quad \tilde{T}_{ja} = vT(\delta_{k}, \delta_{j}) \cdot d^i,
\tilde{P}_{b}^i &= hT(\tilde{\partial}^b, \delta_{j}) \cdot d^i, \quad \tilde{P}_{aj}^b = vT(\tilde{\partial}^b, \delta_{j}) \cdot d^i,
\end{align*}
\]

and

\[
\begin{align*}
\tilde{T}_{jk} &= T_{jk} - L_{jk}, \quad \tilde{T}_{ja} = C_{ji}a, \quad \tilde{T}_{ja} = -C_{ja}, \quad \tilde{T}_{ja} = 0, \quad \tilde{T}_{jb} = -\tilde{P}_{a}^i \tag{55}
\end{align*}
\]

The formulas for torsion can be generalized for hv–bundles (on every shell we must write (53) or (55) in dependence of the type of shell, vector or co-vector one, we are dealing).

### 3.5.3 d–Curvatures in v- and cv–bundles

The curvature \( R (X, Y) Z = XY^\bullet \mathbb{R} \cdot Z = D_X D_Y Z - D_Y D_X Z - D_{[X,Y]}Z \).

One holds the next properties for the h- and v–decompositions of curvature:

\[
\begin{align*}
\mathfrak{v}R (X, Y) hZ &= 0, \quad hR (X, Y) vZ = 0, \\
R (X, Y) Z &= hR (X, Y) hZ + vR (X, Y) vZ. 
\end{align*}
\]

From (56) and the equation \( R (X, Y) = -R (Y, X) \) we get that the curvature of a d–connection \( D \) in \( \mathcal{E} \) is completely determined by the following six d–tensor fields:

\[
\begin{align*}
P_{h, jk}^i &= d^i \cdot R (\delta_{k}, \delta_{j}) \delta_{h}, \quad P_{b, jk}^a = \delta^a \cdot R (\delta_{k}, \delta_{j}) \delta_{b}, \tag{57}
\end{align*}
\]

By a direct computation, using (14), (15), (27), (28) and (57) we get:

\[
\begin{align*}
R_{h, jk}^i &= \delta_h L_{hj}^i - \delta_j L_{jk}^i + L_{hj}^m L_{mk}^i - L_{hk}^i L_{mj}^i + C_{h, i}^a R_{j, k}^a, \\
R_{b, jk}^a &= \delta_k L_{b, jk}^a - \delta_j L_{b, jk}^a - L_{b, jk}^i L_{ck}^a - L_{b, jk}^a L_{c, jk}^a + C_{b, c}^c R_{j, k}^c, \\
P_{j, ka}^i &= \partial_a L_{j, ka}^i - (\delta_k C_{j, a}^i + L_{j, k}^i C_{j, a}^i - L_{j, k}^i C_{j, a}^i + L_{a, k}^i C_{j, c}^i + C_{j, k}^b P_{j, b}^a, \\
P_{b, ka}^i &= \partial_a L_{b, ka}^i - (\delta_k C_{b, a}^i + L_{b, k}^i C_{b, a}^i - L_{b, k}^i C_{b, a}^i + L_{d, b}^i C_{b, d}^i + C_{b, d}^c P_{j, d}^a, \\
S_{j, bc}^i &= \delta_j C_{j, c}^i - \delta_h C_{j, c}^i + C_{j, h}^i C_{j, c}^i - C_{b, h}^i C_{j, b}^i, \\
S_{b, cd}^a &= \partial_a C_{b, c}^a + \partial_e C_{b, c}^a + C_{b, c}^a C_{b, d}^a - C_{b, d}^c C_{b, e}^a.
\end{align*}
\]
We note that d–torsions (53) and d–curvatures (58) are computed in explicit form by particular cases of d–connections (41), (43) and (44). For cv–bundles we have

\[
\begin{align*}
\tilde{R}^i_{hjk} &= d^i \cdot R(\delta_k, \delta_j) \delta_h, \quad \tilde{R}^b_{a,jk} = \tilde{\delta}_a \cdot R(\delta_k, \delta_j) \tilde{\delta}^b, \\
\tilde{P}^c_{j,k} &= d^i \cdot R(\tilde{\delta}^c, \delta_k) \delta_j, \quad \tilde{P}^b_{a,k} = \tilde{\delta}_a \cdot R(\tilde{\delta}^c, \delta_k) \tilde{\delta}^b, \\
\tilde{S}^{abc}_{j} &= d^i \cdot R(\tilde{\delta}^c, \tilde{\delta}^b) \delta_j, \quad \tilde{S}^{bd}_{a} = \tilde{\delta}_a \cdot R(\tilde{\delta}^d, \tilde{\delta}^b) \tilde{\delta}^b.
\end{align*}
\]

and

\[
\begin{align*}
\tilde{R}^i_{hjk} &= \tilde{\delta}_h L^i_{hj} - \tilde{\delta}_j L^i_{hk} + L^m_{hk} L^i_{mk} - L^m_{hj} L^i_{mk} + C^i_{h} c \tilde{R}_{ajk}, \\
\tilde{R}^b_{a,jk} &= \tilde{\delta}_k L^b_{a,j} - \tilde{\delta}_j L^b_{a,k} + L^b_{c,k} L^c_{a,j} - L^b_{c,j} L^c_{a,k} + \tilde{\delta}_c b c \tilde{R}_{c,jk}, \\
\tilde{P}^a_{j,k} &= \tilde{\delta}^a L^b_{j,k} - (\delta^a \tilde{C}^a_{c}) + L^b_{c,k} \tilde{C}^a_{d} - L^b_{c,j} \tilde{C}^a_{d} c + \tilde{C}^a_{j} b \tilde{P}_{a,k}, \\
\tilde{P}^b_{c,k} &= \tilde{\delta}_c L^b_{c,k} - \delta^c b \tilde{C}^a_{c} - \tilde{C}^b_{j} c \tilde{C}^a_{j} h, \\
\tilde{S}^{abc}_{j} &= \tilde{\delta}^a \tilde{C}^{b}_{c} + \tilde{\delta}^b \tilde{C}^{a}_{c} + \tilde{\delta}^c \tilde{C}^{a}_{j} + \tilde{\delta}^d \tilde{C}^{a}_{d} - \tilde{\delta}^{b} \tilde{C}^{a}_{c}.
\end{align*}
\]

The formulas for curvature can be also generalized for hvc–bundles (on every shell we must write (53) or (54) in dependence of the type of shell, vector or co-vector one, we are dealing).

4 Generalizations of Finsler Geometry

We outline the basic definitions and formulas for Finsler, Lagrange and generalized Lagrange spaces (constructed on tangent bundle) and for Cartan, Hamilton and generalized Hamilton spaces (constructed on cotangent bundle). The original results are given in details in the monographs [23, 22], see also developments for suberbundles [42, 43].

4.1 Finsler Spaces

The Finsler geometry is modeled on tangent bundle TM.

**Definition 4.1.** A Finsler space (manifold) is a pair \(F^n = (M, F(x, y))\) where \(M\) is a real \(n\)–dimensional differentiable manifold and \(F : TM \to \mathcal{R}\) is a scalar function which satisfy the following conditions:

1. \(F\) is a differentiable function on the manifold \(\tilde{TM} = TM \setminus \{0\}\) and \(F\) is continuous on the null section of the projection \(\pi : TM \to M\);

2. \(F\) is a positive function, homogeneous on the fibers of the TM, i.e. \(F(x, \lambda y) = \lambda F(x, y), \lambda \in \mathcal{R}\);

3. The Hessian of \(F^2\) with elements

\[
g^{(F)}_{ij}(x, y) = \frac{1}{2} \frac{\partial^2 F^2}{\partial y^i \partial y^j}
\]

is positively defined on \(\tilde{TM}\).
The function $F(x,y)$ and $g_{ij}(x,y)$ are called respectively the fundamental function and the fundamental (or metric) tensor of the Finsler space $F$.

One considers "anisotropic" (depending on directions $y^i$) Christoffel symbols, for simplicity we write $g_{ij}^{(F)} = g_{ij}$,

$$\gamma^j_{jk}(x,y) = \frac{1}{2}g^{ir}\left(\frac{\partial g_{rk}}{\partial x^j} + \frac{\partial g_{jr}}{\partial x^k} - \frac{\partial g_{jk}}{\partial x^r}\right),$$

which are used for definition of the Cartan $N$–connection,

$$N^i_{(c) j} = \frac{1}{2} \frac{\partial}{\partial y^j} \left[ \gamma^i_{nk}(x,y)y^ny^k \right].$$

(62)

This $N$–connection can be used for definition of an almost complex structure like in (45) and to define on $TM$ a $d$–metric

$$G^{(F)}_{ij} = g_{ij}(x,y)dx^i \otimes dx^j + g_{ij}(x,y)\delta y^i \otimes \delta y^j,$$

(63)

with $g_{ij}(x,y)$ taken as (61).

Using the Cartan $N$–connection (62) and Finsler metric tensor (61) (or, equivalently, the $d$–metric (63)) we can introduce the canonical $d$–connection

$$D\Gamma_{(N)} = \Gamma^\alpha_{(c) \beta \gamma} = (L^i_{(c) jk}, C^i_{(c) jk})$$

with the coefficients computed like in (48) and (42) with $h_{ab} \rightarrow g_{ij}$. The $d$–connection $D\Gamma_{(N)}$ has the unique property that it is torsionless and satisfies the metricity conditions both for the horizontal and vertical components, i.e. $D\alpha g_{\beta \gamma} = 0$.

The $d$–curvatures

$$\check{R}^i_{h,jk} = \{\check{R}^i_{h,jk}, \check{P}^i_{j,k} \, ^l, S^i_{(c) j,k,l}\}$$

on a Finsler space provided with Cartan $N$–connection and Finsler metric structures are computed following the formulas (58) when the $a, b, c...$ indices are identified with $i, j, k, ...$ indices. It should be emphasized that in this case all values $g_{ij}, \Gamma^\alpha_{(c) \beta \gamma}$ and $R^\alpha_{(c) \beta \gamma \delta}$ are defined by a fundamental function $F(x,y)$.

In general, we can consider that a Finsler space is provided with a metric $g_{ij} = \partial^2 F^2 / 2\partial y^i \partial y^j$, but the $N$–connection and $d$–connection are be defined in a different manner, even not determined by $F$.

### 4.2 Lagrange and Generalized Lagrange Spaces

The notion of Finsler spaces was generalized by J. Kern [17] and R. Miron [19]. It is widely developed in monographs [23] and extended to superspaces in Refs. [41, 42, 43].

The idea of extension was to consider instead of the homogeneous fundamental function $F(x,y)$ in a Finsler space a more general one, a Lagrangian $L(x,y)$, defined as a differentiable mapping $L : (x,y) \in TM \rightarrow L(x,y) \in \mathcal{R}$, of class $C^\infty$ on manifold $TM$ and continuous on the null section $0 : M \rightarrow TM$ of the projection $\pi : TM \rightarrow M$. A Lagrangian is regular if it is differentiable and the Hessian

$$g_{ij}^{(L)}(x,y) = \frac{1}{2} \frac{\partial^2 L^2}{\partial y^i \partial y^j},$$

(64)

is of rank $n$ on $M$. 

23
Definition 4.2. A Lagrange space is a pair $L^n = (M, L(x,y))$ where $M$ is a smooth real $n$–dimensional manifold provided with regular Lagrangian $L(x,y)$ structure $L : TM \to \mathcal{R}$ for which $g_{ij}(x,y)$ from (64) has a constant signature over the manifold $\tilde{T}M$.

The fundamental Lagrange function $L(x,y)$ defines a canonical $N$–connection

$$N^i_{(cL)j} = \frac{1}{2} \frac{\partial}{\partial y^j} \left[ g^{ik} \left( \frac{\partial^2 L^2}{\partial y^k \partial y^h} y^h - \frac{\partial L}{\partial x^k} \right) \right]$$

as well a d–metric

$$G(L) = g_{ij}(x,y) dx^i \otimes dx^j + g_{ij}(x,y) \delta y^i \otimes \delta y^j, \quad (65)$$

with $g_{ij}(x,y)$ taken as (64). As well we can introduce an almost Kählerian structure and an almost Hermitian model of $L^n$, denoted as $H^2n$ as in the case of Finsler spaces but with a proper fundamental Lagrange function and metric tensor $g_{ij}$. The canonical metric d–connection $D\Gamma(N^i_{(cL)j}) = \Gamma^\alpha_{(cL)\beta\gamma} = \left( L^i_{(cL)jk} C^i_{(cL)jk} \right)$ is to computed by the same formulas (48) and (42) with $h_{ab} \to g_{ij}(L)$, for $N^i_{(cL)j}$. The d–torsions (53) and d–curvatures (58) are defined, in this case, by $L^i_{(cL)jk}$ and $C^i_{(cL)jk}$. We also note that instead of $N^i_{(cL)j}$ and $\Gamma^\alpha_{(cL)\beta\gamma}$ one can consider on a $L^n$–space arbitrary $N$–connections $N^i_{ij}$, d–connections $\Gamma^\alpha_{\beta\gamma}$ which are not defined only by $L(x,y)$ and $g_{ij}^{(L)}$ but can be metric, or non–metric with respect to the Lagrange metric.

The next step of generalization is to consider an arbitrary metric $g_{ij}(x,y)$ on $TM$ instead of (64) which is the second derivative of ”anisotropic” coordinates $y^i$ of a Lagrangian [19].

Definition 4.3. A generalized Lagrange space is a pair $GL^n = (M, g_{ij}(x,y))$ where $g_{ij}(x,y)$ is a covariant, symmetric d–tensor field, of rank $n$ and of constant signature on $TM$.

One can consider different classes of N– and d–connections on $TM$, which are compatible (metric) or non compatible with (65) for arbitrary $g_{ij}(x,y)$. We can apply all formulas for d–connections, N–curvatures, d–torsions and d–curvatures as in a v–bundle $\mathcal{E}$, but reconsidering them on $TM$, by changing $h_{ab} \to g_{ij}(x,y)$ and $N^i_{ij} \to N^i_{ij}$.

4.3 Cartan Spaces

The theory of Cartan spaces (see, for instance, [28, 16]) was formulated in a new fashion in R. Miron’s works [20] by considering them as duals to the Finsler spaces (see details and references in [22]). Roughly, a Cartan space is constructed on a cotangent bundle $T^*M$ like a Finsler space on the corresponding tangent bundle $TM$.

Consider a real smooth manifold $M$, the cotangent bundle $(T^*M, \pi^*, M)$ and the manifold $\tilde{T}^*M = T^*M \setminus \{0\}$.

Definition 4.4. A Cartan space is a pair $C^n = (M, K(x,p))$ such that $K : T^*M \to \mathcal{R}$ is a scalar function which satisfy the following conditions:
1. $K$ is a differentiable function on the manifold $\widetilde{T^*M} = T^*M \setminus \{0\}$ and continuous on the null section of the projection $\pi^* : T^*M \to M$;

2. $K$ is a positive function, homogeneous on the fibers of the $T^*M$, i. e. $K(x, \lambda p) = \lambda F(x, p), \lambda \in \mathcal{R}$;

3. The Hessian of $K^2$ with elements
   \[\hat{g}^{ij}(x, p) = \frac{1}{2} \frac{\partial^2 K^2}{\partial p_i \partial p_j}\] (66)
is positively defined on $\widetilde{T^*M}$.

The function $K(x, y)$ and $\hat{g}^{ij}(x, p)$ are called respectively the fundamental function and the fundamental (or metric) tensor of the Cartan space $C^n$. We use symbols like ”$\hat{g}$” as to emphasize that the geometrical objects are defined on a dual space.

One considers ”anisotropic” (depending on directions, momenta, $p_i$) Christoffel symbols, for simplicity, we write the inverse to (66) as $\tilde{g}^{ij}(x, p)$.

\[\tilde{\gamma}^{ij} = \frac{1}{2} \tilde{\delta}^{ir} \left( \tilde{\delta}_j \tilde{g}^{rk} + \tilde{\delta}_k \tilde{g}^{jr} - \tilde{\delta}_r \tilde{g}^{jk} \right), \tilde{\gamma} = \frac{\partial}{\partial p_n}.\] (67)

This N–connection can be used for definition of an almost complex structure like in (45) and to define on $T^*M$ a d–metric
\[\tilde{G}(x, p) = \tilde{g}^{ij}(x, p) dx^i \otimes dx^j + \tilde{g}^{ij}(x, p) dp_i \otimes dp_j,\] (68)
with $\tilde{g}^{ij}(x, p)$ taken as (66).

Using the canonical N–connection (67) and Finsler metric tensor (66) (or, equivalently, the d–metric (68) we can introduce the canonical d–connection
\[D \tilde{\Gamma}(\tilde{N}(k)) = \tilde{\Gamma}^{\alpha}_{(k)\beta\gamma} = \left( \tilde{H}^i_{(k)jk}, \tilde{C}_{(k)i}^{jk} \right)\]
with the coefficients
\[\tilde{H}^i_{(k)jk} = \frac{1}{2} \tilde{g}^{ir} \left( \tilde{\delta}_j \tilde{g}_{rk} + \tilde{\delta}_k \tilde{g}_{jr} - \tilde{\delta}_r \tilde{g}_{jk} \right), \tilde{C}_{(k)i}^{jk} = \tilde{g}_{is} \tilde{\gamma}^{sk} \tilde{g}^{jk},\]
The d–connection $D \tilde{\Gamma}(\tilde{N}(k))$ has the unique property that it is torsionless and satisfies the metricity conditions both for the horizontal and vertical components, i. e. $\tilde{D}_\alpha \tilde{\gamma} = 0$.

The d–curvatures
\[\tilde{R}^\alpha_{(k)i\beta\gamma}(k)^{\beta\gamma}(k) = \{\tilde{R}^i_{(k)hjk}, P^i_{(k)jkm}, \tilde{S}^{ijkl}_{(k)i}\}\]
on a Finsler space provided with Cartan N–connection and Finsler metric structures are computed following the formulas (60) when the $a, b, c...$ indices are identified with $i, j, k...$ indices. It should be emphasized that in this case all values $\tilde{g}_{ij}, \tilde{\Gamma}_{(k)i}^{\beta\gamma}$ and $\tilde{R}^\alpha_{(k)i\beta\gamma}$ are defined by a fundamental function $K(x, p)$.

In general, we can consider that a Cartan space is provided with a metric $\tilde{g}^{ij} = \partial^2 K^2 / 2 \partial p_i \partial p_j$, but the N–connection and d–connection could be defined in a different manner, even not be determined by $K$.  

25
4.4 Generalized Hamilton and Hamilton Spaces

The geometry of Hamilton spaces was defined and investigated by R. Miron in Refs. [21] (see details and references in [22]). It was developed on the cotangent bundle as a dual geometry to the geometry of Lagrange spaces. Here we start with the definition of generalized Hamilton spaces and then consider the particular case.

**Definition 4.5.** A generalized Hamilton space is a pair
\[ GH^n = (M, \tilde{g}^{ij}(x,p)) \]
where \( M \) is a real \( n \)-dimensional manifold and \( \tilde{g}^{ij}(x,p) \) is a contravariant, symmetric, nondegenerate of rank \( n \) and of constant signature on \( \tilde{T}^*M \).

The value \( \tilde{g}^{ij}(x,p) \) is called the fundamental (or metric) tensor of the space \( GH^n \). One can define such values for every paracompact manifold \( M \). In general, a \( \tilde{N} \)-connection on \( GH^n \) is not determined by \( \tilde{g}^{ij} \). Therefore we can consider arbitrary coefficients \( \tilde{N}_{ij}(x,p) \) and define on \( T^*M \) a d–metric like (69)
\[
\tilde{G} = \tilde{g}_{\alpha\beta}(\tilde{u}) \delta^\alpha \otimes \delta^\beta = \tilde{g}_{ij}(\tilde{u}) d^i \otimes d^j + \tilde{g}^{ij}(\tilde{u}) \delta_i \otimes \delta_j,
\]
This \( \tilde{N} \)-coefficients \( \tilde{N}_{ij}(x,p) \) and d–metric structure (69) allow to define an almost Kähler model of generalized Hamilton spaces and to define canonical d–connections, d–torsions and d–curvatures (see respectively the formulas (42), (43), (55) and (58) with the fiber coefficients redefined for the cotangent bundle \( T^*M \ ).

A generalized Hamilton space \( GH^n = (M, \tilde{g}^{ij}(x,p)) \) is called reducible to a Hamilton one if there exists a Hamilton function \( H(x,p) \) on \( T^*M \) such that
\[
\tilde{g}^{ij}(x,p) = \frac{1}{2} \frac{\partial^2 H}{\partial p_i \partial p_j}.
\]

**Definition 4.6.** A Hamilton space is a pair \( H^n = (M, H(x,p)) \) such that \( H : T^*M \to \mathbb{R} \) is a scalar function which satisfy the following conditions:

1. \( H \) is a differentiable function on the manifold \( \tilde{T}^*M = T^*M \setminus \{0\} \) and continuous on the null section of the projection \( \pi^* : T^*M \to M \);
2. The Hessian of \( H \) with elements (77) is positively defined on \( \tilde{T}^*M \) and \( \tilde{g}^{ij}(x,p) \) is nondegenerate matrix of rank \( n \) and of constant signature.

For Hamilton spaces the canonical N–connection (defined by \( H \) and its Hessian) exists,
\[
\tilde{N}_{ij} = \frac{1}{4} \{\tilde{g}_{ij}, H\} - \frac{1}{2} \left( \tilde{g}_{ik} \frac{\partial^2 H}{\partial p_k \partial x^j} + \tilde{g}_{jk} \frac{\partial^2 H}{\partial p_k \partial x^i} \right),
\]
where the Poisson brackets, for arbitrary functions \( f \) and \( g \) on \( T^*M \), act as
\[
\{f, g\} = \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial x^i} - \frac{\partial g}{\partial p_i} \frac{\partial f}{\partial x^i}.
\]
The canonical d–connection \( D\hat{\Gamma} (\hat{N}(c)) = \hat{\Gamma}_{(c)\beta\gamma} = \left( \hat{H}^{i}_{(c)jk}, \hat{C}^{(c)ijk}_{i} \right) \) is defined by the coefficients
\[
\hat{H}^{i}_{(c)jk} = \frac{1}{2} \hat{g}^{is} \left( \hat{\delta}_{j} \hat{g}_{sk} + \hat{\delta}_{k} \hat{g}_{js} - \hat{\delta}_{s} \hat{g}_{jk} \right), \quad \hat{C}^{(c)ijk}_{i} = -\frac{1}{2} \hat{g}_{ks} \hat{\partial}^{i} \hat{g}^{sk}.
\]
In result we can compute the d–torsions and d–curvatures like on cv–bundle or on Cartan spaces. On Hamilton spaces all such objects are defined by the Hamilton function \( H(x, p) \) and indices have to be reconsidered for co–fibers of the co-tangent bundle.

5 Clifford Bundles and N–Connections

The theory of anisotropic spinors was extended on higher order anisotropic (ha) spaces \[44, 43, 49\]. In brief, such spinors will be called ha–spinors which are defined as some Clifford ha–structures defined with respect to a distinguished quadratic form (37) on a hvc–bundle. For simplicity, the bulk of formulas will be given with respect to higher order vector bundles. To rewrite such formulas for hvc–bundles is to consider for the “dual” shells of higher order anisotropy some dual vector spaces and associated dual spinors.

5.1 Distinguished Clifford Algebras

The typical fiber of dv–bundle \( \xi_{d}, \pi_{d} : HE \oplus V_{1}E \oplus \ldots \oplus V_{z}E \to E \) is a d-vector space, \( \mathcal{F} = h\mathcal{F} \oplus v_{1}\mathcal{F} \oplus \ldots \oplus v_{z}\mathcal{F} \), split into horizontal \( h\mathcal{F} \) and verticals \( v_{p}\mathcal{F}, p = 1, \ldots, z \) subspaces, with a bilinear quadratic form \( G(g, h) \) induced by a hvc–bundle metric (37). Clifford algebras (see, for example, Refs. \[12, 27\]) formulated for d-vector spaces will be called Clifford d–algebras \[38, 48\]. We shall consider the main properties of Clifford d–algebras. The proof of theorems will be based on the technique developed in Ref. \[12, 43, 49\] correspondingly adapted to the distinguished character of spaces in consideration.

Let \( k \) be a number field (for our purposes \( k = \mathbb{R} \) or \( k = \mathbb{C}, \mathbb{R} \) and \( \mathbb{C} \), are, respectively real and complex number fields) and define \( \mathcal{F}, \) as a d-vector space on \( k \) provided with non-degenerate symmetric quadratic form (metric) \( G \). Let \( C \) be an algebra on \( k \) (not necessarily commutative) and \( j : \mathcal{F} \to C \) a homomorphism of underlying vector spaces such that \( j(u)^{2} = G(u) \cdot 1 \) (1 is the unity in algebra \( C \) and d-vector \( u \in \mathcal{F} \)). We are interested in definition of the pair \((C, j)\) satisfying the next universality conditions. For every \( k \)-algebra \( A \) and arbitrary homomorphism \( \varphi : \mathcal{F} \to A \) of the underlying d-vector spaces, such that \((\varphi(u))^{2} \to G(u) \cdot 1 \), there is a unique homomorphism of algebras \( \psi : C \to A \) transforming the chain of maps into a commutative diagram.

The algebra solving this problem will be denoted as \( C(\mathcal{F}, A) \) [equivalently as \( C(G) \) or \( C(\mathcal{F}) \)] and called as Clifford d–algebra associated with pair \((\mathcal{F}, G)\).

**Theorem 5.1.** The above-presented chain of maps has a unique solution \((C, j)\) up to isomorphism.

**Proof:** See Refs. \[39, 43\].

Now we re–formulate for d–algebras the Chevalley theorem \[13\]:

**Theorem 5.2.** The Clifford d–algebra
\[
C(h\mathcal{F} \oplus v_{1}\mathcal{F} \oplus \ldots \oplus v_{z}\mathcal{F}, g + h_{1} + \ldots + h_{z})
\]
is naturally isomorphic to \( C(g) \otimes C(h_1) \otimes \ldots \otimes C(h_z) \).

**Proof.** See Refs. \[39, 43\].

From the presented Theorems, we conclude that all operations with Clifford \( d \)-algebras can be reduced to calculations for \( C(h\mathcal{F}, g) \) and \( C(v_{(p)}\mathcal{F}, h_{(p)}) \) which are usual Clifford algebras of dimension \( 2^n \) and, respectively, \( 2^{mp} \) \[12, 4\].

Of special interest is the case when \( k = \mathcal{R} \) and \( \mathcal{F} \) is isomorphic to vector space \( \mathcal{R}^{p+q,a+b} \) provided with quadratic form

\[
-x_1^2 - \ldots - x_p^2 + x_{p+q}^2 - y_1^2 - \ldots - y_a^2 + \ldots + y_{a+b}^2.
\]

In this case, the Clifford algebra, denoted as \( (C^{p,q}, C^{a,b}) \), is generated by the symbols \( e_1^{(x)}, e_2^{(x)}, \ldots, e_{p+q}^{(x)}, e_1^{(y)}, e_2^{(y)}, \ldots, e_{a+b}^{(y)} \) satisfying properties

\[
(e_i)^2 = -1 \quad (1 \leq i \leq p), 
(e_j)^2 = -1 \quad (1 \leq j \leq a), 
(e_k)^2 = 1 \quad (p+1 \leq k \leq p+q), 
(e_j)^2 = 1 \quad (n+1 \leq s \leq a+b), 
\]

\( e_i e_j = -e_j e_i, \quad i \neq j \).

Explicit calculations of \( C^{p,q} \) and \( C^{a,b} \) are possible by the using isomorphisms \[12, 27\]

\[
C^{p+q,n+q} \simeq C^{p,q} \otimes M_2(\mathcal{R}) \otimes \ldots \otimes M_2(\mathcal{R}) \simeq C^{p,q} \otimes M_{2^n}(\mathcal{R}) \cong M_{2^n}(C^{p,q}),
\]

where \( M_s(A) \) denotes the ring of quadratic matrices of order \( s \) with coefficients in ring \( A \). Here we write the simplest isomorphisms \( C^{1,0} \simeq \mathcal{C}, C^{0,1} \simeq \mathcal{R} \oplus \mathcal{R} \) and \( C^{2,0} = \mathcal{H} \), where \( \mathcal{H} \) is denoted the body of quaternions.

Now, we emphasize that higher order Lagrange and Finsler spaces, denoted \( H^{2n} \)-spaces, admit locally a structure of Clifford algebra on complex vector spaces. Really, by using almost Hermitian structure \( J_\alpha \beta \) and considering complex space \( C^n \) with nondegenerate quadratic form \( \sum_{a=1}^{n} |z_a|^2 \), \( z_a \in \mathbb{C}^2 \) induced locally by metric \( \mathcal{F} \) (rewritten in complex coordinates \( z_a = x_a + iy_a \)) we define Clifford algebra \( \mathcal{C}^n = \mathcal{C}^1 \otimes \ldots \otimes \mathcal{C}^1 \), where \( \mathcal{C}^1 = \mathbb{C} \oplus \mathbb{C} \) or in consequence, \( \mathcal{C}^n \simeq C^{n,0} \otimes_{\mathcal{R}} \mathcal{C} \simeq C^{0,n} \otimes_{\mathcal{R}} \mathcal{C} \). Explicit calculations lead to isomorphisms

\[
\mathcal{C}^2 = C^{0,2} \otimes_{\mathcal{R}} \mathcal{C} \approx M_2(\mathcal{R}) \otimes_{\mathcal{R}} \mathcal{C} \approx M_2\left(\mathcal{C}^n\right), \quad C^{2p} \approx M_{2p}(C)
\]

and

\[
\mathcal{C}^{2p+1} \approx M_{2p}(C) \oplus M_{2p}(C),
\]

which show that complex Clifford algebras, defined locally for \( H^{2n} \)-spaces, have periodicity 2 on \( p \).

Considerations presented in the proof of theorem 2.2 show that map \( j : \mathcal{F} \to C(\mathcal{F}) \) is monomorphic, so we can identify space \( \mathcal{F} \) with its image in \( C(\mathcal{F}, G) \), denoted as \( u \to \mathfrak{u} \), if \( u \in C^{(0)}(\mathcal{F}, G) \) \( (u \in C^{(1)}(\mathcal{F}, G)) \); then \( u = \mathfrak{u} \) (respectively, \( \mathfrak{u} = -u \)).
Definition 5.1. The set of elements \( u \in C(G)^* \), where \( C(G)^* \) denotes the multiplicative group of invertible elements of \( C(F, G) \) satisfying \( \overline{u} \overline{F} u^{-1} \in F \), is called the twisted Clifford \( d \)-group, denoted as \( \tilde{\Gamma}(F) \).

Let \( \tilde{\rho} : \tilde{\Gamma}(F) \to GL(F) \) be the homomorphism given by \( u \to \rho \overline{u} \), where \( \tilde{\rho}_u(w) = \overline{uw}u^{-1} \). We can verify that \( \ker \tilde{\rho} = \mathcal{R}^0 \) is a subgroup in \( \tilde{\Gamma}(F) \).

The canonical map \( j : F \to C(F) \) can be interpreted as the linear map \( \mathcal{F} \to C(F)^0 \) satisfying the universal property of Clifford \( d \)-algebras. This leads to a homomorphism of algebras, \( C(F) \to C(F)^0 \), considered by an anti-involution of \( C(F) \) and denoted as \( u \to {}^t u \). More exactly, if \( u_1 \ldots u_n \in \mathcal{F} \), then \( t_u = u_n \ldots u_1 \) and \( {}^t u = \overline{u} = (-1)^n u_n \ldots u_1 \).

Definition 5.2. The spinor norm of arbitrary \( u \in C(F) \) is defined as
\[
S(u) = {}^t \overline{u} \cdot u \in C(F).
\]

It is obvious that if \( u, u', u'' \in \tilde{\Gamma}(F) \), then \( S(u, u') = S(u) S(u') \) and \( S(uu'u'') = S(u) S(u') S(u'') \). For \( u, u' \in F \), then \( t_u = u_n \ldots u_1 \) and \( {}^t u = S(u) S(u') = S(uu') \).

Let us introduce the orthogonal group \( O(G) \subset GL(G) \) defined by metric \( G \) on \( F \) and denote sets
\[
SO_G = \{ u \in O(G) , \det |u| = 1 \}, \quad Pin_G = \{ u \in \tilde{\Gamma}(F) , S(u) = 1 \}
\]
and \( Spin_G = Pin_G \cap C^0(F) \). By straightforward calculations (see similar considerations in Ref. [12]) we can verify the exactness of these sequences:
\[
1 \to \mathbb{Z}/2 \to Pin_G \to O_G \to 1, \\
1 \to \mathbb{Z}/2 \to Spin_G \to SO_G \to 0, \\
1 \to \mathbb{Z}/2 \to Spin_{(n_E)} \to SO_{(n_E)} \to 1.
\]

We conclude this subsection by emphasizing that the spinor norm was defined with respect to a quadratic form induced by a metric in \( dv \)-bundle \( \mathcal{E}^{<z>} \). This approach differs from those presented in Refs. [2] and [25].

5.2 Clifford Ha–Bundles

We shall consider two variants of generalization of spinor constructions defined for \( d \)-vector spaces to the case of distinguished vector bundle spaces enabled with the structure of N-connection. The first is to use the extension to the category of vector bundles. The second is to define the Clifford fibration associated with compatible linear \( d \)-connection and metric \( G \) on a \( dv \)-bundle. We shall analyze both variants.

5.2.1 Clifford \( d \)-module structure in \( dv \)-bundles

Because functor \( F \to C(F) \) is smooth we can extend it to the category of vector bundles of type
\[
\xi^{<z>} = \{ \pi_d : HE^{<z>} \oplus V_1 E^{<z>} \oplus \ldots \oplus V_2 E^{<z>} \to E^{<z>} \}.
\]
Recall that by $\mathcal{F}$ we denote the typical fiber of such bundles. For $\xi^{<z>}$ we obtain a bundle of algebras, denoted as $C(\xi^{<z>})$, such that $C(\xi^{<z>})_u = C(\mathcal{F}_u)$. Multiplication in every fiber defines a continuous map $C(\xi^{<z>}) \times C(\xi^{<z>}) \to C(\xi^{<z>})$. If $\xi^{<z>}$ is a distinguished vector bundle on number field $k$, $C(\xi^{<z>})$-module, the $d$-module, on $\xi^{<z>}$ is given by the continuous map $C(\xi^{<z>}) \times _{E} \xi^{<z>} \to \xi^{<z>}$ with every fiber $\mathcal{F}_u$ provided with the structure of the $C(\mathcal{F}_u)$-module, correlated with its $k$-module structure, because $\mathcal{F} \subset C(\mathcal{F})$, we have a fiber to fiber map $\mathcal{F} \times _{E} \xi^{<z>} \to \xi^{<z>}$, inducing on every fiber the map $\mathcal{F}_u \times _{E} \xi^{<z>(u)} \to \xi^{<z>(u)}$ ($\mathcal{R}$-linear on the first factor and $k$-linear on the second one). Inversely, every such bilinear map defines on $\xi^{<z>}$ the structure of the $C(\xi^{<z>})$-module by virtue of universal properties of Clifford $d$-algebras. Equivalently, the above-mentioned bilinear map defines a morphism of $v$-bundles

$$m : \xi^{<z>} \to HOM(\xi^{<z>}, \xi^{<z>}) \quad [HOM(\xi^{<z>}, \xi^{<z>})]$$

denotes the bundles of homomorphisms when $(m(u))^2 = G(u)$ on every point.

Vector bundles $\xi^{<z>}$ provided with $C(\xi^{<z>})$-structures are objects of the category with morphisms being morphisms of $dv$-bundles, which induce on every point $u \in \xi^{<z>}$ morphisms of $C(\mathcal{F}_u)$-modules. This is a Banach category contained in the category of finite-dimensional $d$-vector spaces on filed $k$.

Let us denote by $H^s(\mathcal{E}^{<z>}, GL_{n_E}(\mathcal{R}))$, where $n_E = n + m_1 + ... + m_z$, the $s$-dimensional cohomology group of the algebraic sheaf of germs of continuous maps of $dv$-bundle $\mathcal{E}^{<z>}$ with group $GL_{n_E}(\mathcal{R})$ the group of automorphisms of $\mathcal{R}^{n_E}$ (for the language of algebraic topology see, for example, Refs. [12]. We shall also use the group $SL_{n_E}(\mathcal{R}) = \{ A \subset GL_{n_E}(\mathcal{R}), \det A = 1 \}$. Here we point out that cohomologies $H^s(M, Gr)$ characterize the class of a principal bundle $\pi : P \to M$ on $M$ with structural group $Gr$. Taking into account that we deal with bundles distinguished by an $N$-connection we introduce into consideration cohomologies $H^s(\mathcal{E}^{<z>}, GL_{n_E}(\mathcal{R}))$ as distinguished classes ($d$-classes) of bundles $\mathcal{E}^{<z>}$ provided with a global $N$-connection structure.

For a real vector bundle $\xi^{<z>}$ on compact base $\mathcal{E}^{<z>}$ we can define the orientation on $\xi^{<z>}$ as an element $\alpha_d \in H^1(\mathcal{E}^{<z>}, SL_{n_E}(\mathcal{R}))$ whose image on map

$$H^1(\mathcal{E}^{<z>}, SL_{n_E}(\mathcal{R})) \to H^1(\mathcal{E}^{<z>}, GL_{n_E}(\mathcal{R}))$$

is the $d$-class of bundle $\mathcal{E}^{<z>}$. 

**Definition 5.3.** The spinor structure on $\xi^{<z>}$ is defined as an element $\beta_d \in H^1(\mathcal{E}^{<z>}, Spin(n_E))$ whose image in the composition

$$H^1(\mathcal{E}^{<z>}, Spin(n_E)) \to H^1(\mathcal{E}^{<z>}, SO(n_E)) \to H^1(\mathcal{E}^{<z>}, GL_{n_E}(\mathcal{R}))$$

is the $d$-class of $\mathcal{E}^{<z>}$. 

The above definition of spinor structures can be re-formulated in terms of principal bundles. Let $\xi^{<z>}$ be a real vector bundle of rank $n+m$ on a compact base $\mathcal{E}^{<z>}$. If there is a principal bundle $P_d$ with structural group $SO(n_E)$ or $Spin(n_E)$, this bundle $\xi^{<z>}$ can be provided with orientation (or spinor) structure. The bundle $P_d$ is associated with element $\alpha_d \in H^1(\mathcal{E}^{<z>}, SO(n_E))$ (or $\beta_d \in H^1(\mathcal{E}^{<z>}, Spin(n_E))$).
We remark that a real bundle is oriented if and only if its first Stiefel–Whitney d–class vanishes,

$$w_1 (\xi_d) \in H^1 (\xi, \mathcal{Z}/2) = 0,$$

where $H^1 (\mathcal{E}^{<z>}, \mathcal{Z}/2)$ is the first group of Chech cohomology with coefficients in $\mathcal{Z}/2$. Considering the second Stiefel–Whitney class $w_2 (\xi^{<z>}) \in H^2 (\mathcal{E}^{<z>}, \mathcal{Z}/2)$ it is well known that vector bundle $\xi^{<z>}$ admits the spinor structure if and only if $w_2 (\xi^{<z>}) = 0$. Finally, we emphasize that taking into account that base space $\mathcal{E}^{<z>}$ is also a v-bundle, $p : E^{<z>} \to M$, we have to make explicit calculations in order to express cohomologies $H^s (\mathcal{E}^{<z>}, GL_{n+m})$ and $H^s (\mathcal{E}^{<z>}, SO (n + m))$ through cohomologies

$$H^s (M, GL_n), H^s (M, SO (m_1)), ... H^s (M, SO (m_2)),$$

which depends on global topological structures of spaces $M$ and $\mathcal{E}^{<z>}$. For general bundle and base spaces this requires a cumbersome cohomological calculus.

### 5.2.2 Clifford fibration

Another way of defining the spinor structure is to use Clifford fibrations. Consider the principal bundle with the structural group $Gr$ being a subgroup of orthogonal group $O (G)$, where $G$ is a quadratic nondegenerate form. The fibration associated to principal fibration $P (\mathcal{E}^{<z>}, Gr)$ with a typical fiber having Clifford algebra $C (G)$ is, by definition, the Clifford fibration $PC (\mathcal{E}^{<z>}, Gr)$. We can always define a metric on the Clifford fibration if every fiber is isometric to $PC (\mathcal{E}^{<z>}, G)$ (this result is proved for arbitrary quadratic forms $G$ on pseudo–Riemannian bases. If, additionally, $Gr \subset SO (G)$ a global section can be defined on $PC (G)$.

Let $\mathcal{P} (\mathcal{E}^{<z>}, Gr)$ be the set of principal bundles with differentiable base $\mathcal{E}^{<z>}$ and structural group $Gr$. If $g : Gr \to Gr'$ is an homomorphism of Lie groups and $P (\mathcal{E}^{<z>}, Gr) \subset \mathcal{P} (\mathcal{E}^{<z>}, Gr)$ (for simplicity in this subsection we shall denote mentioned bundles and sets of bundles as $P, P'$ and respectively, $\mathcal{P}, \mathcal{P}'$), we can always construct a principal bundle with the property that there is an homomorphism $f : P' \to P$ of principal bundles which can be projected to the identity map of $\mathcal{E}^{<z>}$ and corresponds to isomorphism $g : Gr \to Gr'$. If the inverse statement also holds, the bundle $P'$ is called as the extension of $P$ associated to $g$ and $f$ is called the extension homomorphism denoted as $\tilde{g}$.

Now we can define distinguished spinor structures on bundle spaces.

**Definition 5.4.** Let $P \in \mathcal{P} (\mathcal{E}^{<z>}, O (G))$ be a principal bundle. A distinguished spinor structure of $P$, equivalently a ds-structure of $\mathcal{E}^{<z>}$ is an extension $\tilde{P}$ of $P$ associated to homomorphism $h : PinG \to O (G)$ where $O (G)$ is the group of orthogonal rotations, generated by metric $G$, in bundle $\mathcal{E}^{<z>}$. So, if $\tilde{P}$ is a spinor structure of the space $\mathcal{E}^{<z>}$, then $\tilde{P} \in \mathcal{P} (\mathcal{E}^{<z>}, PinG)$.

The definition of spinor structures on varieties was given in Ref. [8] one had been proved that a necessary and sufficient condition for a space time to be orientable is to admit a global field of orthonormalized frames. We mention that spinor structures can be also defined on varieties modeled on Banach spaces [11]. As we have shown similar constructions are possible for the cases when space time has the structure of a v-bundle with an N-connection.
Definition 5.5. A special distinguished spinor structure, ds-structure, of principal bundle \( P = P(\mathcal{E}^{<z>},SO(G)) \) is a principal bundle \( \tilde{P} = \tilde{P}(\mathcal{E}^{<z>},\text{Spin}G) \) for which a homomorphism of principal bundles \( \tilde{p} : \tilde{P} \to P \), projected on the identity map of \( \mathcal{E}^{<z>} \) and corresponding to representation 
\[ R : \text{Spin}G \to SO(G), \]
is defined.

In the case when the base space variety is oriented, there is a natural bijection between tangent spinor structures with a common base. For special ds–structures we can define, as for any spinor structure, the concepts of spin tensors, spinor connections, and spinor covariant derivations (see Refs. [48, 39]).

5.3 Almost Complex Spinor Structures

Almost complex structures are an important characteristic of \( H^{2n} \)-spaces and of osculator bundles \( \text{Osc}^{k=2k_1}(M) \), where \( k_1 = 1, 2, ... \). For simplicity in this subsection we restrict our analysis to the case of \( H^{2n} \)-spaces. We can rewrite the almost Hermitian metric [23], \( H^{2n} \)-metric in complex form [38]:
\[ G = H_{ab}(z,\xi) dz^a \otimes dz^b, \]  
where
\[ z^a = x^a + iy^a, \quad \bar{z}^a = x^a - iy^a, \quad H_{ab}(z,\xi) = g_{ab}(x,y) \big|_{y=y(z,\xi)}, \]
and define almost complex spinor structures. For given metric (71) on \( H^{2n} \)-space there is always a principal bundle \( P^U \) with unitary structural group \( U(n) \) which allows us to transform \( H^{2n} \)-space into v-bundle \( \xi^U \approx P^U \times U(n) \mathbb{R}^{2n} \). This statement will be proved after we introduce complex spinor structures on oriented real vector bundles [12].

Let us consider momentarily \( k = \mathcal{C} \) and introduce into consideration [instead of the group \( \text{Spin}(n) \)] the group \( \text{Spin}^c \times \mathbb{Z}/2U(1) \) being the factor group of the product \( \text{Spin}(n) \times U(1) \) with the respect to equivalence
\[ (y,z) \sim (-y,-a), \quad y \in \text{Spin}(m). \]
This way we define the short exact sequence
\[ 1 \to U(1) \to \text{Spin}^c(n) \to SO(n) \to 1, \tag{72} \]
where \( \rho^c(y,a) = \rho^c(y) \). If \( \lambda \) is oriented, real, and rank \( n, \gamma \)-bundle \( \pi : E_\lambda \to M^n \), with base \( M^n \), the complex spinor structure, spin structure, on \( \lambda \) is given by the principal bundle \( P \) with structural group \( \text{Spin}^c(m) \) and isomorphism \( \lambda \approx P \times_{\text{Spin}^c(n)} \mathbb{R}^n \) (see (72)). For such bundles the categorial equivalence can be defined as
\[ \epsilon^c : \mathcal{E}_C^\top(M^n) \to \mathcal{E}_C^\lambda(M^n), \tag{73} \]
where \( \epsilon^c(E^c) = P \star_{\text{Spin}^c(n)} E^c \) is the category of trivial complex bundles on \( M^n, \mathcal{E}_C^\lambda(M^n) \) is the category of complex v-bundles on \( M^n \) with action of Clifford bundle.
$C(\lambda), P_{\Delta Spin^c(n)}$ and $E^c$ is the factor space of the bundle product $P \times_M E^c$ with respect to the equivalence $(p, e) \sim (g g^{-1}, e), p \in P, e \in E^c$, where $g \in Spin^c(n)$ acts on $E$ by via the imbedding $Spin(n) \subset C^{0,n}$ and the natural action $U(1) \subset C$ on complex v-bundle $\xi^c, E^c = t_0 \xi^c$, for bundle $\pi^c : E^c \rightarrow M^n$.

Now we return to the bundle $\xi = \mathcal{E}^{<1>}$. A real v-bundle (not being a spinor bundle) admits a complex spinor structure if and only if there exist a homomorphism $\sigma : U(n) \rightarrow Spin^c(2n)$ defining a commutative diagram. The explicit construction of $\sigma$ for arbitrary $\gamma$-bundle is given in Refs. [38, 44, 43, 49]. Let $\lambda$ be a complex, rank $n$, spinor bundle with

$$\tau : Spin^c(n) \times \mathbb{Z}/2 U(1) \rightarrow U(1)$$

the homomorphism defined by formula $\tau (\lambda, \delta) = \delta^2$. For $P_s$ being the principal bundle with fiber $Spin^c(n)$ we introduce the complex linear bundle $L(\lambda^c) = P_s \times_{Spin^c(n)} \mathcal{C}$ defined as the factor space of $P_s \times \mathcal{C}$ on equivalence relation

$$(pt, z) \sim (p, l(t)^{-1} z),$$

where $t \in Spin^c(n)$. This linear bundle is associated to complex spinor structure on $\lambda^c$.

If $\lambda^c$ and $\lambda'^c$ are complex spinor bundles, the Whitney sum $\lambda^c \oplus \lambda'^c$ is naturally provided with the structure of the complex spinor bundle. This follows from the holomorphism

$$\omega' : Spin^c(n) \times Spin^c(n') \rightarrow Spin^c(n+n'),$$

given by formula $[(\beta, z), (\beta', z')] \rightarrow [\omega(\beta, \beta'), zz']$, where $\omega$ is the homomorphism making the chain of maps into a commutative diagram. Here, $z, z' \in U(1)$. It is obvious that $L(\lambda^c \oplus \lambda'^c)$ is isomorphic to $L(\lambda^c) \otimes L(\lambda'^c)$.

We conclude this subsection by formulating our main result on complex spinor structures for $H^{2n}$-spaces:

**Theorem 5.3.** Let $\lambda^c$ be a complex spinor bundle of rank $n$ and $H^{2n}$-space considered as a real vector bundle $\lambda^c \oplus \lambda'^c$ provided with almost complex structure $J^\alpha \beta$; multiplication on $i$ is given by $\left( \begin{array}{cc} 0 & -\delta_i^j \\ \delta_i^j & 0 \end{array} \right)$. Then, the chain of maps define a commutative diagram up to isomorphisms $e^c$ and $\bar{e}^c$ defined as in [73], $\mathcal{H}$ is functor $E^c \rightarrow E^c \otimes L(\lambda^c)$ and $\mathcal{E}^{0,2n}(M^n)$ is defined by functor $\mathcal{E}^c(M^n) \rightarrow \mathcal{E}^{0,2n}(M^n)$ given as correspondence $E^c \rightarrow \Lambda(C^n) \otimes E^c$ (which is a categorial equivalence), $\Lambda(C^n)$ is the exterior algebra on $C^n$. $W$ is the real bundle $\lambda^c \oplus \lambda'^c$ provided with complex structure.

**Proof:** See Refs. [33, 44, 43, 49].

Now consider bundle $P \times_{Spin^c(n)} Spin^c(2n)$ as the principal $Spin^c(2n)$-bundle, associated to $M \oplus M$ being the factor space of the product $P \times Spin^c(2n)$ on the equivalence relation $(p, t, h) \sim (p, \mu(t)^{-1} h)$. In this case the categorial equivalence [73] can be rewritten as

$$e^c(E^c) = P \times_{Spin^c(n)} Spin^c(2n) \Delta_{Spin^c(2n)} E^c$$

and seen as factor space of $P \times Spin^c(2n) \times_M E^c$ on equivalence relation

$$(pt, h, e) \sim (p, \mu(t)^{-1} h, e)$$

and $(p, h_1, h_2, e) \sim (p, h_1, h_2^{-1} e)$.
(projections of elements \( p \) and \( e \) coincides on base \( M \)). Every element of \( \epsilon^c (E^c) \) can be represented as \( P \Delta_{spin^c(n)} E^c \), i.e., as a factor space \( P \Delta E^c \) on equivalence relation \((pt, e) \sim (p, \mu^c (t), e)\), when \( t \in Spin^c(n) \). The complex line bundle \( L (\lambda^c) \) can be interpreted as the factor space of \( P \times_{Spin^c(n)} C \) on equivalence relation \((pt, \delta) \sim (p, r(t)^{-1} \delta)\).

Putting \((p, e) \otimes (p, \delta) (p, \delta e)\) we introduce morphism
\[
\epsilon^c (E) \times L (\lambda^c) \rightarrow \epsilon^c (\lambda^c)
\]
with properties
\[
(pt, e) \otimes (pt, \delta) \rightarrow (pt, \delta e) = (p, \mu^c (t)^{-1} \delta e),
\]
\[
(p, \mu^c (t)^{-1} e) \otimes (p, l(t)^{-1} e) \rightarrow (p, \mu^c (t) r(t)^{-1} \delta e)
\]
pointing to the fact that we have defined the isomorphism correctly and that it is an isomorphism on every fiber. \( \square \)

6 Spinors and N–Connection Geometry

The purpose of this section is to show how a corresponding abstract spinor technique entailing notational and calculations advantages can be developed for arbitrary splits of dimensions of a \( d \)-vector space \( F = hF \oplus v_1 F \oplus ... \oplus v_z F \), where \( \dim hF = n \) and \( \dim v_p F = m_p \). For convenience we shall also present some necessary coordinate expressions.

6.1 D–Spinor Techniques

The problem of a rigorous definition of spinors on locally anisotropic spaces (d–spinors) was posed and solved \([38, 39]\) in the framework of the formalism of Clifford and spinor structures on \( \nu \)-bundles provided with compatible nonlinear and distinguished connections and metric. We introduced d-spinors as corresponding objects of the Clifford d-algebra \( C (F, G) \), defined for a \( d \)-vector space \( F \) in a standard manner (see, for instance, \([12]\)) and proved that operations with \( C (F, G) \) can be reduced to calculations for \( C (hF, g), C (v_1 F, h_1), ... \) and \( C (v_z F, h_z) \), which are usual Clifford algebras of respective dimensions \( 2^n, 2^{m_1}, ..., \) and \( 2^{m_z} \) (if it is necessary we can use quadratic forms \( g \) and \( h_p \) correspondingly induced on \( hF \) and \( v_p F \) by a metric \( G \) \([37]\)). Considering the orthogonal subgroup \( O(G) \subset GL(G) \) defined by a metric \( G \) we can define the d-spinor norm and parametrize d-spinors by ordered pairs of elements of Clifford algebras \( C (hF, g) \) and \( C (v_p F, h_p) \), \( p = 1, 2, ..., z \). We emphasize that the splitting of a Clifford d-algebra associated to a \( dv \)-bundle \( \mathcal{E}^{<z>} \) is a straightforward consequence of the global decomposition defining a N-connection structure in \( \mathcal{E}^{<z>} \).

In this subsection we shall omit detailed proofs which in most cases are mechanical but rather tedious. We can apply the methods developed in \([27, 15]\) in a straightforward manner on \( h \)- and \( v \)-subbundles in order to verify the correctness of affirmations.

6.1.1 Clifford d–algebra, d–spinors and d–twistors

In order to relate the succeeding constructions with Clifford d-algebras \([38]\) we consider a la-frame decomposition of the metric \([37]\):
\[
G_{<\alpha, \beta>}(u) = l_{<\alpha>}(u) l_{<\beta>}(u) G_{<\alpha, \beta>},
\]

34
where the frame d-vectors and constant metric matrices are distinguished as

\[ I_{<\alpha>}(u) = \begin{pmatrix} \hat{l}_j^\alpha(u) & 0 & \ldots & 0 \\ 0 & \hat{l}_{a1}^\alpha(u) & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & \hat{l}_{az}^\alpha(u) \end{pmatrix}, \]

\[ G_{<\alpha><\beta>} = \begin{pmatrix} g_{ij} & 0 & \ldots & 0 \\ 0 & h_{a1b1} & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & h_{azbz} \end{pmatrix}, \]

\( g_{ij} \) and \( h_{a1b1}, \ldots, h_{azbz} \) are diagonal matrices with \( g_{ii} = h_{a1a1} = \ldots = h_{azbz} = \pm 1. \)

To generate Clifford d-algebras we start with matrix equations

\[ \sigma_{<\alpha>}\sigma_{<\beta>} + \sigma_{<\beta>}\sigma_{<\alpha>} = -G_{<\alpha><\beta>}I, \quad (76) \]

where \( I \) is the identity matrix, matrices \( \sigma_{<\alpha>} \) (\( \sigma \)-objects) act on a d-vector space \( \mathcal{F} = h\mathcal{F} \oplus v_1\mathcal{F} \oplus \ldots \oplus v_z\mathcal{F} \) and their components are distinguished as

\[ \sigma_{<\alpha>} = \left\{ \left( \sigma_{<\alpha>} \right)_k^i = \begin{pmatrix} (\sigma_{<\alpha>})_{k}^{\hat{b}} & 0 & \ldots & 0 \\ 0 & (\sigma_{<\alpha>})_{k}^{\hat{a}_1} & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & (\sigma_{<\alpha>})_{k}^{\hat{a}_z} \end{pmatrix} \right\}, \quad (77) \]

indices \( \beta, \gamma, \ldots \) refer to spin spaces of type \( \mathcal{S} = \mathcal{S}_{(h)} \oplus \mathcal{S}_{(v_1)} \oplus \ldots \oplus \mathcal{S}_{(v_z)} \) and underlined Latin indices \( \hat{j}, \hat{k}, \ldots \) and \( \hat{b}_1, \hat{c}_1, \ldots, \hat{b}_z, \hat{c}_z \ldots \) refer respectively to h-spin space \( \mathcal{S}_{(h)} \) and \( v_p \)-spin space \( \mathcal{S}_{(v_p)}, (p = 1, 2, \ldots, z) \) which are correspondingly associated to a h- and \( v_p \)-decomposition of a d-vbundle \( \mathcal{E}^{<z>} \). The irreducible algebra of matrices \( \sigma_{<\alpha>} \) of minimal dimension \( N \times N \), where \( N = N_{(n)} + N_{(m_1)} + \ldots + N_{(m_z)} \), \( \dim \mathcal{S}_{(h)} = N_{(n)} \) and \( \dim \mathcal{S}_{(v_p)} = N_{(m_p)} \), has these dimensions

\[ N_{(n)} = \begin{cases} 2^{(n-1)/2}, & n = 2k + 1 \\ 2^{n/2}, & n = 2k; \end{cases} \quad \text{and} \quad N_{(m_p)} = \begin{cases} 2^{(m_p-1)/2}, & m_p = 2k_p + 1 \\ 2^{m_p}, & m_p = 2k_p; \end{cases} \]

where \( k = 1, 2, \ldots, k_p = 1, 2, \ldots \).

The Clifford d-algebra is generated by sums on \( n + 1 \) elements of form

\[ A_1 I + B^i \sigma_i + C^{ij} \sigma_{ij} + D^{ijk} \sigma_{ijk} + \ldots \quad (78) \]

and sums of \( m_p + 1 \) elements of form

\[ A_{2(p)} I + B^{\hat{a}_p} \sigma_{\hat{a}_p} + C^{\hat{a}_p\hat{b}_p} \sigma_{\hat{a}_p\hat{b}_p} + D^{\hat{a}_p\hat{b}_p\hat{c}_p} \sigma_{\hat{a}_p\hat{b}_p\hat{c}_p} + \ldots \]

with antisymmetric coefficients \( C^{ij} = C^{ij}, C^{\hat{a}_p\hat{b}_p} = C^{[\hat{a}_p\hat{b}_p]}, D^{\hat{a}_p\hat{b}_p\hat{c}_p} = D^{[\hat{a}_p\hat{b}_p\hat{c}_p]}, \ldots \) and matrices \( \sigma_{ij} = \sigma_{[i} \sigma_{j]}, \sigma_{\hat{a}_p\hat{b}_p} = \sigma_{[\hat{a}_p \hat{b}_p]}, \sigma_{ijk} = \sigma_{[i} \sigma_{j} \sigma_{k]}, \ldots \). Really, we have \( 2^{n+1} \)
coefficients \( (A_1, C^{ij}, D^{ijk}, \ldots) \) and \( 2^{m_p+1} \) coefficients \( (A_{2(p)}, C^{a\bar{d}p}, D^{a\bar{d}p\bar{c}p}, \ldots) \) of the Clifford algebra on \( F \).

For simplicity, we shall present the necessary geometric constructions only for h-spin spaces \( S_{(h)} \) of dimension \( N(n) \). Considerations for a v-spin space \( S_{(v)} \) are similar but with proper characteristics for a dimension \( N(m) \).

In order to define the scalar (spinor) product on \( S_{(h)} \) we introduce into consideration this finite sum (because of a finite number of elements \( \sigma_{ij \ldots} \)):

\[ \epsilon_{km}^i = \frac{1}{2} (\sigma_{ij} \sigma_{ij})^l_k + \frac{2}{2!} (\sigma_{ij} \sigma_{ij})^l_k + \frac{2^2}{3!} (\sigma_{ij} \sigma_{ij})^l_k + \cdots \]  

which can be factorized as

\[ \epsilon_{km}^i = N(n) \epsilon_{km}^i \]  

and

\[ \epsilon_{km}^i = 2N(n) \epsilon_{km}^i \]  

\[ \epsilon_{km}^i = 0 \]  

\[ \epsilon_{km}^i = 2N(n) \epsilon_{km}^i \]  

Antisymmetry of \( \sigma_{ij \ldots} \) and the construction of the objects \( \{78\} \)\( \{81\} \) define the properties of \( \epsilon \)-objects \( \epsilon_{km} \) and \( \epsilon_{km} \) which have an eight-fold periodicity on \( n \) (see details in \[27\] and, with respect to locally anisotropic spaces, \[38\]).

For even values of \( n \) it is possible the decomposition of every h-spin space \( S_{(h)} \) into irreducible h-spin spaces \( S_{(h)} \) and \( S'_{(h)} \) (one considers splitting of h-indices, for instance, \( L = L \oplus L', \mathbb{M} = M \oplus M', \ldots \); for \( v \)-indices we shall write \( a_p = A_p \oplus A'_p, b_p = B_p \oplus B'_p, \ldots \) and defines new \( \epsilon \)-objects

\[ \epsilon_{lm}^i = \frac{1}{2} (\epsilon_{lm}^i + \epsilon_{lm}^j) \]  

and

\[ \epsilon_{lm}^i = \frac{1}{2} (\epsilon_{lm}^j + \epsilon_{lm}^i) \]  

We shall omit similar formulas for \( \epsilon \)-objects with lower indices.

In general, the spinor \( \epsilon \)-objects should be defined for every shell of anisotropy where instead of dimension \( n \) we shall consider the dimensions \( m_p, 1 \leq p \leq z, \) of shells.

We define a d–spinor space \( S_{(n,m)} \) as a direct sum of a horizontal and a vertical spinor spaces, for instance,

\[ S_{(8k,8k')} = S_0 \oplus S'_0 \oplus S_{v0} \oplus S'_{v0} \oplus S_{(8k,8k'+1)} = S_0 \oplus S'_0 \oplus S_{v0}, \ldots \]

\[ S_{(8k+4,8k+5)} = S_{\triangle \Delta} \oplus S'_{\triangle \Delta} \oplus S_{\triangle \Delta}, \ldots \]

The scalar product on a \( S_{(n,m)} \) is induced by (corresponding to fixed values of \( n \) and \( m \)) \( \epsilon \)-objects considered for h- and \( v \)-components. We present also an example for \( S_{(n,m_1, \ldots, m_z)} \):

\[ S_{(8k+4,8k(1)+5, \ldots, 8k(p)+4, \ldots 8k(2))} = \mathbb{S} \oplus \mathbb{S}_\triangle \oplus S_{\triangle \Delta} \oplus \ldots \oplus S_{(1)\Delta} \oplus S'_{(1)\Delta} \oplus \ldots \oplus S_{(z)\Delta} \oplus S'_{(z)\Delta} \]

Having introduced d-spinors for dimensions \( (n, m_1 + \ldots + m_z) \) we can write out the generalization for ha–spaces of twistor equations \[27\] by using the distinguished \( \sigma \)-objects

\[ (\sigma_{<\hat{a}>})^\gamma_{\hat{a}} = \frac{\delta \omega^\beta}{\delta u^{<\hat{b}>}} = \frac{1}{n + m_1 + \ldots + m_z} \]  

\[ G_{<\hat{a}> <\hat{b}>} (\sigma^\gamma)^{\hat{a}}_{\hat{a}} = \frac{\delta \omega^\beta}{\delta u^\gamma} \]  

(83)
where $|\beta|$ denotes that we do not consider symmetrization on this index. The general solution of (83) on the d-vector space $F$ looks like as

$$\omega_\beta = \Omega_\beta + u^{<\hat{a}>}(\sigma_{<\hat{a}>})_\beta^\gamma \Pi^\gamma,$$

(84)

where $\Omega_\beta$ and $\Pi^\gamma$ are constant d-spinors. For fixed values of dimensions $n$ and $m = m_1 + ... + m_z$ we must analyze the reduced and irreducible components of h- and v-parts of equations (83) and their solutions (84) in order to find the symmetry properties of a d-twistor $Z^\alpha$ defined as a pair of d-spinors $Z^\alpha = (\omega^\alpha, \pi_{\beta}')$, where $\pi_{\beta}' = \pi_{\beta}'(0) \in \tilde{S}(n,m_1,...,m_z)$ is a constant dual d-spinor.

The problem of definition of spinors and twistors on ha-spaces was firstly considered in [48] (see also [35]) in connection with the possibility to extend the equations (84) and theirs solutions (85), by using nearly autoparallel maps, on curved, locally isotropic or anisotropic, spaces. We note that the definition of twistors have been extended to higher order anisotropic spaces with trivial N– and d–connections.

### 6.1.2 Mutual transforms of d-tensors and d-spinors

The spinor algebra for spaces of higher dimensions can not be considered as a real alternative to the tensor algebra as for locally isotropic spaces of dimensions $n = 3, 4$ [27]. The same holds true for ha–spaces and we emphasize that it is not quite convenient to perform a spinor calculus for dimensions $n, m >> 4$. Nevertheless, the concept of spinors is important for every type of spaces, we can deeply understand the fundamental properties of geometrical objects on ha–spaces, and we shall consider in this subsection some questions concerning transforms of d-tensor objects into d-spinor ones.

### 6.1.3 Transformation of d-tensors into d-spinors

In order to pass from d-tensors to d-spinors we must use $\sigma$-objects (77) written in reduced or irreduced form (in dependence of fixed values of dimensions $n$ and $m$):

$$(\sigma_{<\hat{a}>})^\gamma_\beta, \quad (\sigma_{<\hat{a}>})_{\beta\gamma}, \quad (\sigma_{<\hat{a}>})_{\beta\gamma}, \quad ..., \quad (\sigma_{<\hat{a}>})_{bc}, \quad ..., \quad (\sigma_{<\hat{a}>})_{Jk}, \quad ..., \quad (\sigma_{<\hat{a}>})_{AA'}, \quad ..., \quad (\sigma_{<\hat{a}>})_{II'}, \quad ..., \quad (85)$$

It is obvious that contracting with corresponding $\sigma$-objects (85) we can introduce instead of d-tensors indices the d-spinor ones, for instance,

$$\omega_\beta = (\sigma_{<\hat{a}>})_{\beta\gamma} \omega_{<\hat{a}>}, \quad \omega_{AB'} = (\sigma_{<\hat{a}>})_{AB'} \omega_{<\hat{a}>}, \quad ..., \quad \zeta_2^i = (\sigma^k)_{i2} \zeta_k,$$

For d-tensors containing groups of antisymmetric indices there is a more simple procedure of theirs transforming into d-spinors because the objects

$$(\sigma_{<\hat{a}>})_{\hat{a}\beta\hat{a}}, \quad (\sigma_{<\hat{a}>})_{\hat{a}\beta\hat{a}}, \quad ..., \quad (\sigma_{<\hat{a}>})_{II'}, \quad ..., \quad (86)$$

can be used for sets of such indices into pairs of d-spinor indices. Let us enumerate some properties of $\sigma$-objects of type (86) (for simplicity we consider only h-components having q
indices $\hat{i}, \hat{j}, \hat{k}, \ldots$ taking values from 1 to $n$; the properties of $v_p$-components can be written in a similar manner with respect to indices $\hat{a}_p, \hat{b}_p, \hat{c}_p, \ldots$ taking values from 1 to $m$):

\[
(\sigma_{\hat{i} \cdots \hat{j}})_{kl}^{kl} \begin{cases} 
\text{symmetric on } k, l \text{ for } n - 2q \equiv 1, 7 \pmod{8}; \\
\text{antisymmetric on } k, l \text{ for } n - 2q \equiv 3, 5 \pmod{8}
\end{cases}
\]  

(87)

for odd values of $n$, and an object

\[
(\sigma_{\hat{i} \cdots \hat{j}})^{IJ} \left( (\sigma_{\hat{i} \cdots \hat{j}})^{I'J'} \right) \begin{cases} 
\text{symmetric on } I, J (I', J') \text{ for } n - 2q \equiv 0 \pmod{8}; \\
\text{antisymmetric on } I, J (I', J') \text{ for } n - 2q \equiv 4 \pmod{8}
\end{cases}
\]  

(88)

or

\[
(\sigma_{\hat{i} \cdots \hat{j}})^{IJ} = \pm \left( (\sigma_{\hat{i} \cdots \hat{j}})^{I'J'} \right)_{IJ} \quad n + 2q \equiv 6 \pmod{8};
\]

\[
\quad n + 2q \equiv 2 \pmod{8},
\]  

(89)

with vanishing of the rest of reduced components of the d-tensor $(\sigma_{\hat{i} \cdots \hat{j}})_{kl}^{kl}$ with prime/unprime sets of indices.

### 6.1.4 Fundamental d–spinors

We can transform every d–spinor $\xi^\alpha = (\xi^i, \xi^a_1, \ldots, \xi^a_z)$ into a corresponding d-tensor. For simplicity, we consider this construction only for a $h$-component $\xi^i$ on a $h$-space being of dimension $n$. The values

\[
\xi^\alpha \xi^\beta (\sigma_{\hat{i} \cdots \hat{j}})_{\alpha \beta} \quad (n \text{ is odd})
\]  

(90)

or

\[
\xi^I \xi^J (\sigma_{\hat{i} \cdots \hat{j}})_{IJ} \quad \text{or} \quad \xi^{I'} \xi^{J'} (\sigma_{\hat{i} \cdots \hat{j}})_{I'J'} \quad (n \text{ is even})
\]  

(91)

with a different number of indices $\hat{i} \cdots \hat{j}$, taken together, defines the h-spinor $\xi^i$ to an accuracy to the sign. We emphasize that it is necessary to choose only those h-components of d-tensors (90) (or (91)) which are symmetric on pairs of indices $\alpha, \beta$ (or $IJ$ (or $I', J'$)) and the number $q$ of indices $\hat{i} \cdots \hat{j}$ satisfies the condition (as a respective consequence of the properties (87) and/or (88), (89))

\[
n - 2q \equiv 0, 1, 7 \pmod{8}.
\]  

(92)

Of special interest is the case when

\[
q = \frac{1}{2} (n \pm 1) \quad (n \text{ is odd})
\]  

(93)

or

\[
q = \frac{1}{2} n \quad (n \text{ is even}).
\]  

(94)

If all expressions (90) and/or (91) are zero for all values of $q$ with the exception of one or two ones defined by the conditions (92), (93) (or (94)), the value $\xi^i$ (or $\xi^I$ (or $\xi^{I'}$)) is called a fundamental h-spinor. Defining in a similar manner the fundamental v-spinors we can introduce fundamental d-spinors as pairs of fundamental h- and v-spinors. Here we remark that a $h(v_p)$-spinor $\xi^i$ ($\xi_{\hat{a}_p}$) (we can also consider reduced components) is always a fundamental one for $n(m) < 7$, which is a consequence of (94).
This subsection is devoted to the differential geometry of d–spinors in higher order anisotropic spaces. We shall use denotations of type

\[ v^{<\alpha>} = (v^i, v^{<a>}) \in \sigma^{<\alpha>} = (\sigma^i, \sigma^{<a>}) \]

and

\[ \zeta^{\alpha}_{\nu} = (\zeta^{\alpha}_{\nu}, \zeta^{\alpha}_{\nu}) \in \sigma^{\alpha}_{\nu} = (\sigma^{\alpha}_{\nu}, \sigma^{\alpha}_{\nu}) \]

for, respectively, elements of modules of d-vector and irreduced d-spinor fields (see details in [38]). D-tensors and d-spinor tensors (irreduced or reduced) will be interpreted as elements of corresponding \( \sigma \)-modules, for instance,

\[ q^{<\alpha><\beta>} = (q^i_{<\alpha><\beta>}, q^{a}_{<\alpha><\beta>}) \in \sigma^{<\alpha><\beta>} = (\sigma^i_{<\alpha><\beta>}, \sigma^{a}_{<\alpha><\beta>}), \]

where

\[ (\sigma^{<\alpha><\beta>} (u))_{<\alpha><\beta>} = \gamma^{<\alpha><\beta>} (\sigma^{<\alpha><\beta>} (u))_{<\alpha><\beta>}, \]

which is a consequence of formulas (76)–(82). In brief we can write (95) as

\[ g^{<\alpha><\beta>} = \epsilon^{<\alpha><\beta>}_{\alpha_{\beta}, \beta_{\alpha}} \]

if the \( \sigma \)-objects are considered as a fixed structure, whereas \( \epsilon \)-objects are treated as caring the metric “dynamics”, on higher order anisotropic space. This variant is used, for instance, in the so-called 2-spinor geometry [27] and should be preferred if we have to make explicit the algebraic symmetry properties of d-spinor objects by using metric decomposition (97). An alternative way is to consider as fixed the algebraic structure of \( \epsilon \)-objects and to use variable components of \( \sigma \)-objects of type (98) for developing a variational d-spinor approach to gravitational and matter field interactions on ha-spaces (the spinor Ashtekar variables [3] are introduced in this manner).

We note that a d–spinor metric

\[ \epsilon_{\nu \tau} = \begin{pmatrix} 
\epsilon_{ij} & 0 & \ldots & 0 \\
0 & \epsilon_{k_1 k_2} & \ldots & 0 \\
\ldots & \ldots & \ldots & \ldots \\
0 & 0 & \ldots & \epsilon_{k_s k_t} 
\end{pmatrix} \]

on the d-spinor space \( S = (S_{(h)}, S_{(v_1)}, \ldots, S_{(v_s)}) \) can have symmetric or antisymmetric h (v_\( p \)) -components \( \epsilon_{ij}, \epsilon_{k_1 k_2}, \ldots, \epsilon_{k_s k_t} \), see \( \epsilon \)-objects. For simplicity, in order to avoid cumbersome calculations connected with eight-fold periodicity on dimensions \( n \) and \( m_\( p \) \) of a ha-space \( \mathcal{E}<\nu> \), we shall develop a general d-spinor formalism only by using irreduced spinor spaces \( S_{(h)} \) and \( S_{(v_\( p \))}. \)

39
6.2.1 D-covariant derivation on ha–spaces

Let $\mathcal{E}^{<z>}$ be a ha-space. We define the action on a d-spinor of a d-covariant operator

\[
\nabla_{<\alpha>} = (\nabla_i, \nabla_{<\alpha>}) = (\sigma_{<\alpha>})^a_{\beta} \nabla_{a,\beta} = \left((\sigma_i)^{a_1}_{\alpha_1} \nabla_{a_1,\alpha_1}, (\sigma_{<\alpha>})^a_{\beta} \nabla_{a,\beta}\right)
\]

\[
= ((\sigma_i)^{a_1}_{\alpha_1} \nabla_{a_1,\alpha_1}, (\sigma_{a_1})^{a_2}_{\alpha_2} \nabla_{(a_1)a_2}, \ldots, (\sigma_{a_p})^{a_{p+1}}_{\alpha_{p+1}} \nabla_{(a_p)a_{p+1}}, \ldots, (\sigma_{a_z})^{a_2}_{\alpha_2} \nabla_{(z)a_2})
\]

(in brief, we shall write

\[
\nabla_{<\alpha>} = \nabla_{a_1a_2} = \left(\nabla_{a_1a_2}, \nabla_{(1)a_1a_2}, \ldots, \nabla_{(p)a_1a_2}, \ldots, \nabla_{(z)a_1a_2}\right)
\]

as maps

\[
\nabla_{a_1a_2} : \sigma^\beta \rightarrow \sigma_{<\alpha>}^\beta = \sigma_{a_1a_2}^\beta =
\]

\[
\left(\sigma_i^{\beta}_{(a_1a_2)}, \sigma^{(1)a_1}_{a_1a_2}, \ldots, \sigma^{(p)a_p}_{a_1a_2}, \ldots, \sigma^{(z)a_z}_{a_1a_2}\right)
\]

satisfying conditions

\[
\nabla_{<\alpha>}(\xi^\beta + \eta^\beta) = \nabla_{<\alpha>}\xi^\beta + \nabla_{<\alpha>}\eta^\beta,
\]

and

\[
\nabla_{<\alpha>}(f \xi^\beta) = f \nabla_{<\alpha>} \xi^\beta + \xi^\beta \nabla_{<\alpha>} f
\]

for every $\xi^\beta, \eta^\beta \in \mathfrak{g}$ and $f$ being a scalar field on $\mathcal{E}^{<z>}$. It is also required that one holds the Leibnitz rule

\[
(\nabla_{<\alpha>} \zeta^\beta) \eta^\gamma = \nabla_{<\alpha>} (\zeta^\beta \eta^\gamma) - \zeta^\beta \nabla_{<\alpha>} \eta^\gamma
\]

and that $\nabla_{<\alpha>}$ is a real operator, i.e. it commutes with the operation of complex conjugation:

\[
\nabla_{<\alpha>} \psi_{\alpha_\beta\gamma\ldots} = \nabla_{<\alpha>}(\psi_{\alpha_\beta\gamma\ldots}).
\]

Let now analyze the question on uniqueness of action on d–spinors of an operator $\nabla_{<\alpha>}$ satisfying necessary conditions. Denoting by $\nabla_{<\alpha>}$ and $\nabla_{a}$ two such d-covariant operators we consider the map

\[
(\nabla_{<\alpha>} - \nabla_{a}) : \sigma^\beta \rightarrow \sigma_{a_1a_2}^\beta = \left(\sigma_i^{\beta}_{(a_1a_2)}, \sigma^{(1)a_1}_{a_1a_2}, \ldots, \sigma^{(p)a_p}_{a_1a_2}, \ldots, \sigma^{(z)a_z}_{a_1a_2}\right).
\] (98)

Because the action on a scalar $f$ of both operators $\nabla_{<\alpha>}^{(1)}$ and $\nabla_{a}$ must be identical, i.e.

\[
\nabla_{<\alpha>}^{(1)} f = \nabla_{a} f,
\]

the action (98) on $f = \omega^\beta_2 \xi^\beta_2$ must be written as

\[
(\nabla_{<\alpha>} - \nabla_{a})(\omega^\beta_2 \xi^\beta_2) = 0.
\]

In consequence we conclude that there is an element $\Theta_{a_1a_2}^\gamma \in \sigma_{a_1a_2}$ for which

\[
\nabla_{a_1a_2}^{(1)} \xi^\gamma = \nabla_{a_1a_2} \xi^\gamma + \Theta_{a_1a_2}^\gamma \xi^\gamma, \nabla_{a_1a_2}^{(1)} \omega^\beta_2 = \nabla_{a_1a_2} \omega^\beta_2 - \Theta_{a_1a_2}^\gamma \omega^\gamma.
\] (99)
The action of the operator (98) on a d-vector \( v^{\langle \beta \rangle} = v^{|\beta|} \) can be written by using formula (99) for both indices \( \beta_1 \) and \( \beta_2 \):

\[
\left( \nabla^{(1)}_{\langle \alpha \rangle} - \nabla_{\langle \alpha \rangle} \right) v^{\beta_1 \beta_2} = \Theta_{\langle \alpha \rangle \gamma_2}^{\beta_1} v^{\beta_2 \gamma_1} + \Theta_{\langle \alpha \rangle \gamma_1}^{\beta_2} v^{\beta_1 \gamma_2}
\]

= (\Theta_{\langle \alpha \rangle \gamma_2}^{\beta_1} \delta_{\alpha_2}^{\beta_2} + \Theta_{\langle \alpha \rangle \gamma_1}^{\beta_2} \delta_{\alpha_1}^{\beta_1}) v^{\gamma_1 \gamma_2} = Q^{\langle \beta \rangle}_{\langle \alpha \rangle < \gamma \rangle} v^{\langle \gamma \rangle},
\]

where

\[
Q^{\langle \beta \rangle}_{\langle \alpha \rangle < \gamma \rangle} = Q^{\beta_1 \beta_2}_{\alpha_1 \alpha_2} = \Theta_{\langle \alpha \rangle \gamma_2}^{\beta_1} \delta_{\alpha_2}^{\beta_2} + \Theta_{\langle \alpha \rangle \gamma_1}^{\beta_2} \delta_{\alpha_1}^{\beta_1}.
\]  

(100)

The d-commutator \( \nabla_{\langle \alpha \rangle} \nabla_{\langle \beta \rangle} \) defines the d-torsion. So, applying operators \( \nabla^{(1)}_{\langle \alpha \rangle} \nabla^{(1)}_{\langle \beta \rangle} \) and \( \nabla_{\langle \alpha \rangle} \nabla_{\langle \beta \rangle} \) on \( f = \omega_{\beta} \xi_{\beta} \) we can write

\[
T^{(1)}_{\langle \gamma \rangle}_{\langle \alpha \rangle < \beta \rangle} - T^{(1)}_{\langle \beta \rangle}_{\langle \alpha \rangle < \gamma \rangle} = Q^{\langle \gamma \rangle}_{\langle \alpha \rangle < \beta \rangle} - Q^{\langle \gamma \rangle}_{\langle \alpha \rangle < \beta \rangle}
\]

with \( Q^{\langle \gamma \rangle}_{\langle \alpha \rangle < \beta \rangle} \) from (100).

The action of operator \( \nabla^{(1)}_{\langle \alpha \rangle} \) on d-spinor tensors of type \( \chi_{\beta_1 \beta_2 \ldots}^{\beta_1 \beta_2 \ldots} \) must be constructed by using formula (99) for every upper index \( \beta_1 \beta_2 \ldots \) and formula (100) for every lower index \( \alpha_1 \alpha_2 \alpha_3 \ldots \).

6.2.2 Infeld–van der Waerden coefficients

Let \( \delta_{\alpha}^{\alpha} = \left( \delta_{\alpha}^{\frac{1}{2}}, \delta_{\alpha}^{\frac{3}{2}}, \ldots, \delta_{\alpha}^{\frac{N}{2}}, \delta_{\alpha}^{\frac{1}{2}}, \delta_{\alpha}^{\frac{3}{2}}, \ldots, \delta_{\alpha}^{\frac{N}{2}} \right) \) be a d–spinor basis. The dual to it basis is denoted as

\[
\delta_{\alpha}^{\alpha} = \left( \delta_{\alpha}^{\frac{1}{2}}, \delta_{\alpha}^{\frac{3}{2}}, \ldots, \delta_{\alpha}^{\frac{N}{2}}, \delta_{\alpha}^{\frac{1}{2}}, \delta_{\alpha}^{\frac{3}{2}}, \ldots, \delta_{\alpha}^{\frac{N}{2}} \right).
\]

A d-spinor \( \kappa^{\alpha} \in \sigma^{\alpha} \) has components \( \kappa^{\alpha} = \kappa^{\alpha_i} \). Taking into account that \( \delta_{\alpha}^{\beta} \delta_{\beta}^{\alpha} \nabla_{\alpha}^{\beta} \kappa^{\gamma} = \nabla_{\alpha}^{\beta} \kappa^{\gamma} \), we write out the components \( \nabla_{\alpha}^{\beta} \kappa^{\gamma} \) in the form

\[
\delta_{\alpha}^{\beta} \delta_{\gamma}^{\alpha} \nabla_{\alpha}^{\beta} \kappa^{\gamma} = \delta_{\alpha}^{\beta} \delta_{\gamma}^{\alpha} \nabla_{\alpha}^{\beta} \kappa^{\gamma} + \kappa^{\gamma} \delta_{\alpha}^{\beta} \delta_{\gamma}^{\alpha} \nabla_{\alpha}^{\beta} \delta_{\gamma}^{\alpha} = \nabla_{\alpha}^{\beta} \kappa^{\gamma} + \kappa^{\gamma} \delta_{\alpha}^{\beta} \delta_{\gamma}^{\alpha},
\]

(101)

where the coordinate components of the d–spinor connection \( \gamma_{\alpha \beta}^{\gamma} \) are defined as

\[
\gamma_{\alpha \beta}^{\gamma} = \delta_{\alpha}^{\gamma} \delta_{\beta}^{\gamma} \nabla_{\alpha}^{\beta} \delta_{\gamma}^{\alpha}.
\]

(102)

We call the Infeld - van der Waerden d-symbols a set of \( \sigma \)-objects \( (\sigma_{\alpha})^{\alpha \beta} \) parametrized with respect to a coordinate d-spinor basis. Defining

\[
\nabla_{\alpha} = (\sigma_{\alpha})^{\alpha \beta} \nabla_{\alpha}^{\beta},
\]

introducing denotations

\[
\gamma_{\alpha \beta}^{\gamma} = \gamma_{\alpha \beta}^{\gamma} \left( \sigma_{\alpha} \right)^{\alpha \beta}
\]

41
and using properties \(\text{[101]}\), we can write the relations
\[
\begin{align*}
I^\alpha_{\langle\alpha\rangle} \delta^{\beta}_{\beta} \nabla_{\langle\alpha\rangle} \kappa^\beta &= \nabla_{\langle\alpha\rangle} \kappa^\beta + \kappa^\delta \gamma^\beta_{\langle\alpha\rangle} \delta, \\
I^\alpha_{\langle\alpha\rangle} \delta^{\beta}_{\beta} \nabla_{\langle\alpha\rangle} \mu^\beta &= \nabla_{\langle\alpha\rangle} \mu^\beta - \mu^\delta \gamma^\beta_{\langle\alpha\rangle} \delta.
\end{align*}
\]
for d-covariant derivations \(\nabla^\alpha \kappa^\beta\) and \(\nabla^\alpha \mu^\beta\).

We can consider expressions similar to \(\text{[103]}\) for values having both types of d-spinor and d-tensor indices, for instance,
\[
I^\alpha_{\langle\alpha\rangle} l^\gamma_{\langle\gamma\rangle} \delta^{\delta}_{\delta} \nabla_{\langle\alpha\rangle} \theta^\gamma_{\langle\gamma\rangle} = \nabla_{\langle\alpha\rangle} \theta^\gamma_{\langle\gamma\rangle} - \theta^\gamma_{\langle\alpha\rangle} \gamma^\delta_{\langle\delta\rangle} + \theta^\gamma_{\langle\gamma\rangle} \Gamma^\gamma_{\langle\alpha\rangle\langle\gamma\rangle}.
\]

(we can prove this by a straightforward calculation).

Now we shall consider some possible relations between components of d-connections \(\gamma^\delta_{\langle\alpha\rangle\langle\delta\rangle}\) and \(\Gamma^\gamma_{\langle\alpha\rangle\langle\gamma\rangle}\) and derivations of \((\sigma^\alpha_{\langle\alpha\rangle})^\alpha_{\langle\alpha\rangle}\). We can write
\[
\begin{align*}
\Gamma^\gamma_{\langle\alpha\rangle\langle\gamma\rangle} &= I^\alpha_{\langle\alpha\rangle} \nabla_{\langle\gamma\rangle} l^\alpha_{\langle\beta\rangle} = I^\alpha_{\langle\alpha\rangle} \nabla_{\langle\gamma\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\alpha\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\nu_{\langle\alpha\rangle} \nabla_{\langle\gamma\rangle} \left( (\sigma^\alpha_{\langle\alpha\rangle})^\alpha_{\langle\alpha\rangle} \delta^\mu_{\langle\delta\rangle} \delta^\nu_{\langle\gamma\rangle} \right) \\
&= I^\alpha_{\langle\alpha\rangle} \delta^{\nu}_{\nu} \nabla_{\langle\gamma\rangle} l^\alpha_{\langle\beta\rangle} + I^\alpha_{\langle\alpha\rangle} \delta^{\nu}_{\nu} (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\beta\rangle} \nabla_{\langle\gamma\rangle} \delta^\mu_{\langle\delta\rangle} \delta^\nu_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \\
&= I^\alpha_{\langle\alpha\rangle} \nabla_{\langle\gamma\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\beta\rangle} + I^\alpha_{\langle\alpha\rangle} \delta^{\nu}_{\nu} \delta^\mu_{\langle\delta\rangle} \delta^\nu_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \\
&= \Gamma^\gamma_{\langle\alpha\rangle\langle\gamma\rangle} \delta^{\nu}_{\nu} \delta^\mu_{\langle\delta\rangle} \delta^\nu_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \\
\end{align*}
\]
where \(I^\alpha_{\langle\alpha\rangle} = (\sigma^\alpha_{\langle\alpha\rangle})^\alpha_{\langle\alpha\rangle}\), from which one follows
\[
(\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\alpha\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\nu_{\langle\beta\rangle} \Gamma^\gamma_{\langle\alpha\rangle\langle\gamma\rangle} = (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\beta\rangle} \nabla_{\langle\gamma\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\alpha\rangle} + \delta^\nu_{\nu} \delta^\mu_{\langle\delta\rangle} \delta^\nu_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle} \delta_{\langle\gamma\rangle}.
\]

Connecting the last expression on \(\beta\) and \(\nu\) and using an orthonormalized d-spinor basis when \(\gamma^\beta_{\langle\gamma\rangle\langle\beta\rangle} = 0\) (a consequence from \(\text{[102]}\)) we have
\[
\gamma^\mu_{\langle\alpha\rangle\langle\mu\rangle} = \frac{1}{N(n) + N(m_1) + ... + N(m_z)} (\Gamma^\mu_{\langle\alpha\rangle\langle\alpha\rangle} \omega^\beta_{\langle\beta\rangle} - (\sigma^\alpha_{\langle\alpha\rangle})^\beta_{\langle\beta\rangle} \nabla_{\langle\gamma\rangle} (\sigma^\beta_{\langle\beta\rangle})^\mu_{\langle\beta\rangle} ), \quad (104)
\]
where
\[
\Gamma^\mu_{\langle\beta\rangle\langle\beta\rangle} \omega^\beta_{\langle\beta\rangle} = (\sigma^\alpha_{\langle\alpha\rangle})^\mu_{\langle\alpha\rangle} (\sigma^\alpha_{\langle\alpha\rangle})^\beta_{\langle\beta\rangle} \Gamma^\alpha_{\langle\alpha\rangle\langle\beta\rangle}. \quad (105)
\]
We also note here that, for instance, for the canonical and Berwald connections and Christoffel d-symbols we can express d-spinor connection \(\text{[105]}\) through corresponding locally adapted derivations of components of metric and N-connection by introducing corresponding coefficients instead of \(\Gamma^\alpha_{\langle\alpha\rangle\langle\beta\rangle}\) in \(\text{[105]}\) and than in \(\text{[104]}\).

### 6.2.3 D-spinors of ha-space curvature and torsion

The d-tensor indices of the commutator \(\Delta_{\langle\alpha\rangle\langle\beta\rangle}\) can be transformed into d-spinor ones:
\[
\square_{\alpha\beta} = (\sigma_{\langle\alpha\rangle\langle\beta\rangle})_{\alpha\beta} \Delta_{\alpha\beta} = (\square_{ij}, \square_{ab}) = (\square_{ij}, \square_{ab}, ...; \square_{ij}, \square_{ab}, ...; \square_{ij}, \square_{ab}), \quad (106)
\]
with h- and \(v_p\)-components,
\[
\square_{ij} = (\sigma_{\langle\alpha\rangle\langle\beta\rangle})_{ij} \Delta_{\alpha\beta} \quad \text{and} \quad \square_{ab} = (\sigma_{\langle\alpha\rangle\langle\beta\rangle})_{ab} \Delta_{\alpha\beta},
\]

(42)
being symmetric or antisymmetric in dependence of corresponding values of dimensions $n$ and $m_{p}$ (see eight-fold parametrizations. Considering the actions of operator \(106\) on d-spinors $\pi_{\alpha}$ and $\mu_{\alpha}$ we introduce the d-spinor curvature $X_{\alpha \dot{\beta}}$ as to satisfy equations

$$\Box_{\alpha \beta} \pi_{\alpha} = X_{\alpha \dot{\beta}} \pi_{\dot{\beta}}$$

and

$$\Box_{\alpha \beta} \mu_{\alpha} = X_{\alpha \dot{\beta}} \mu_{\dot{\beta}}.$$  \hspace{1cm} (107)

The gravitational d-spinor $\Psi_{\alpha \beta \dot{\gamma}}$ is defined by a corresponding symmetrization of d-spinor indices:

$$\Psi_{\alpha \beta \dot{\gamma}} = X_{(\alpha \beta \dot{\gamma}).}$$ \hspace{1cm} (108)

We note that d-spinor tensors $X_{\alpha \dot{\beta}}$ and $\Psi_{\alpha \beta \dot{\gamma}}$ are transformed into similar 2-spinor objects on locally isotropic spaces \[27\] if we consider vanishing of the N-connection structure and a limit to a locally isotropic space.

Putting $\delta_{\alpha}$ instead of $\mu_{\alpha}$ in \(107\) and using \(108\) we can express respectively the curvature and gravitational d-spinors as

$$X_{\alpha \beta \dot{\gamma}} = \delta_{\alpha} \Box_{\alpha \beta} \delta_{\dot{\gamma}}$$ and

$$\Psi_{\alpha \beta \dot{\gamma}} = \delta_{\dot{\gamma}} \Box_{\alpha \beta} \delta_{\alpha}.$$ 

The d-spinor torsion $T_{\alpha \beta \dot{\gamma}}$ is defined similarly as for d-tensors by using the d-spinor commutator \(106\) and equations

$$\Box_{\alpha \beta} f = T_{\alpha \beta \gamma} \Box_{\gamma} f.$$ 

The d-spinor components $R_{\alpha \beta \dot{\gamma} \dot{\delta}}$ of the curvature d-tensor $R_{\gamma \delta} \alpha \beta$ can be computed by using relations \(105\), and \(106\) and \(108\) as to satisfy the equations

$$(\Box_{\alpha \beta} - T_{\alpha \beta \gamma} \Box_{\gamma} \mu_{\gamma}) V_{\delta \xi \tau} = R_{\alpha \beta \gamma \delta} \delta_{\frac{\xi \tau \mu}{\alpha \beta}} V_{\alpha \beta \gamma},$$

here d-vector $V_{\alpha \beta \gamma}$ is considered as a product of d-spinors, i.e. $V_{\alpha \beta \gamma} = \nu_{\alpha \beta \gamma}$. We find

$$R_{\alpha \beta \gamma \delta} \delta_{\frac{\xi \tau \mu}{\alpha \beta}} = \left( X_{\alpha \beta \gamma \delta} + T_{\alpha \beta \gamma \delta} \gamma_{\xi \tau \mu} \right) \delta_{\frac{\xi \tau \mu}{\alpha \beta}}$$

and

$$+ \left( X_{\alpha \beta \gamma \delta} + T_{\alpha \beta \gamma \delta} \gamma_{\xi \tau \mu} \right) \delta_{\frac{\xi \tau \mu}{\alpha \beta}}.$$ \hspace{1cm} (109)

It is convenient to use this d–spinor expression for the curvature d-tensor

$$R_{\alpha \beta \gamma} \alpha \beta \gamma \delta = \left( X_{\alpha \beta \gamma \delta} + T_{\alpha \beta \gamma \delta} \gamma_{\xi \tau \mu \nu} \right) \delta_{\frac{\xi \tau \mu \nu}{\alpha \beta \gamma}}$$

and

in order to get the d–spinor components of the Ricci d-tensor

$$R_{\alpha \beta \gamma \delta} = X_{\alpha \beta \gamma \delta} + T_{\alpha \beta \gamma \delta} \gamma_{\xi \tau \mu \nu} \delta_{\frac{\xi \tau \mu \nu}{\alpha \beta \gamma}}.$$ \hspace{1cm} (110)

43
and this d-spinor decomposition of the scalar curvature:

\[ \tilde{q} \tilde{R} = R^{\alpha_1 \alpha_2} \gamma_{\alpha_1 \alpha_2} + \tilde{T}^{\alpha_1 \alpha_2} \gamma_{\alpha_1 \alpha_2} \gamma_{\alpha_1 \alpha_2} \]  

(111)

Using (110) and (111), see details in Refs. [27], we define the d–spinor components of the Einstein and \( \Phi_{<\alpha,\beta>} \) d–tensors:

\[ \tilde{G}_{<\alpha,\gamma>} = \tilde{G}^{\gamma_1 \gamma_2 \alpha_1 \alpha_2} = X_{\gamma_1 \gamma_2 \alpha_1 \alpha_2} + T^{\gamma_1 \gamma_2 \alpha_1 \alpha_2} \gamma_{\alpha_1 \alpha_2} \]  

(112)

and

\[ \Phi_{<\alpha,\beta>} = \frac{1}{2(n + m_1 + \ldots + m_2)} \epsilon_{\alpha_1 \alpha_2} \epsilon_{\gamma_1 \gamma_2} \left[ X^{\beta_1 \beta_2} \gamma_{\beta_1 \beta_2} + T^{\alpha_1 \alpha_2 \beta_1 \beta_2} \gamma_{\beta_1 \beta_2} + X^{\gamma_1 \gamma_2 \beta_1 \beta_2} \gamma_{\beta_1 \beta_2} + T^{\alpha_1 \alpha_2 \gamma_1 \gamma_2} \gamma_{\beta_1 \beta_2} \right] 

- \frac{1}{2} \left[ X_{\gamma_1 \gamma_2 \alpha_1 \alpha_2} + T_{\alpha_1 \alpha_2 \gamma_1 \gamma_2} \gamma_{\beta_1 \beta_2} \right] \]  

(113)

We omit this calculus in this work.

**Acknowledgements**

The S. V. work is supported by a NATO/Portugal fellowship at CENTRA, Instituto Superior Tecnico, Lisbon. The author is grateful to R. Ablamowicz, John Ryan and B. Fauser for collaboration and support of his participation at "The 6th International Conference on Clifford Algebras", Cookeville, Tennessee, USA (May 20–25, 2002). He would like to thank J. P. S. Lemos, R. Miron, M. Anastasiei and P. Stavrinos for hospitality and support.
