---

**Abstract**

A novel strain of lactic acid bacteria, WiKim39^T, was isolated from a scallion kimchi sample consisting of fermented chili peppers and vegetables. The isolate was a Gram-positive, rod-shaped, non-motile, catalase-negative and facultatively anaerobic lactic acid bacterium. Phylogenetic analysis of the 16S rRNA gene sequence showed that strain WiKim39^T belonged to the genus *Lactobacillus*, and shared 97.1–98.2% pair-wise sequence similarities with related type strains, *Lactobacillus nodensis*, *Lactobacillus insicii*, *Lactobacillus versmoldensis*, *Lactobacillus tuceti* and *Lactobacillus furfuricola*. The G+C content of the strain based on its genome sequence was 35.3 mol%. The ANI values between WiKim39^T and the closest relatives were lower than 80%. Based on the phenotypic, biochemical, and phylogenetic analyses, strain WiKim39^T represents a novel species of the genus *Lactobacillus*, for which the name *Lactobacillus allii* sp. nov. is proposed. The type strain is WiKim39^T (=KCTC 21077^T=JCM 31938^T).

---

Fermented foods and beverages not only provide important nutrients but also have great potential for maintaining health and preventing disease, and they play an important role in the human diet worldwide [1, 2]. Kimchi is the most well-known traditional fermented food in Korea, and it is made from various raw materials, such as napa cabbage, radish, red pepper, garlic, ginger, radish, and fermented seafood (jeotgal) [3]. Kimchi contains various vitamins and health-promoting components, and it provides health benefits such as antiobesity, anticancer, antioxidation, antimutagen, and anti-atherosclerotic effects [4–6]. In addition, many lactic acid bacteria (LAB) of the genera *Leuconostoc*, *Weissella* and *Lactobacillus* are involved in the fermentation process of kimchi [7]. The genus *Lactobacillus* belongs to the large group of LAB producing lactic acid by carbohydrate fermentation. These bacteria are characterized as Gram-positive, non-spore-forming rods, which have a low G+C content, and are catalase-negative, non-motile microorganisms [8, 9]. Members of the genus *Lactobacillus* are usually found in plants; plant-derived materials such as silage, grains, and foods; and the gastrointestinal tract of humans and animals. *Lactobacillus* strains are currently used as probiotics, starters, and silage inoculants in food and feed fermentation [10]. In the present study, a novel strain within the genus *Lactobacillus*, which is used in the food and feed industries, was isolated from scallion kimchi, and the phenotypic, chemotaxonomic, and molecular characteristics of the novel LAB strain WiKim39^T are presented. Strain WiKim39^T was isolated from scallion kimchi in Gwangju, Korea, using the dilution plating method with MRS agar medium (MRSA; BBL) at 30 °C for 48 h. Single colonies on the plates were transferred to new plates and incubated on MRS agar at 30 °C under anaerobic conditions. The reference strains used in this study, *Lactobacillus nodensis* KACC 16346^T, *Lactobacillus insicii* DSM 29801^T, *Lactobacillus versmoldensis* KCTC 3814^T, *Lactobacillus tuceti* KCTC 21005^T and *Lactobacillus furfuricola* KCTC 21034^T, were cultured in MRS medium according to the culture collection guidelines. Cells of strain WiKim39^T grown on MRS were Gram-stained and visualized under light microscopy and transmission electron microscopy (TEM, Hitachi 7000 electron microscope). Bacterial growth at various pH values (3.0–10.0 in 0.5-unit increments) was measured by inoculating pH-adjusted MRS media with HCl or KOH. The optimum growth temperature and tolerance to NaCl of the cells were also measured. For these studies, cells were grown at temperatures ranging from 15 to 60 °C and in 0–10% (w/v) NaCl for 48 h. Growth was monitored by measuring OD600 using a UV-1600 spectrometer (Shimadzu). Growth under anaerobic conditions was tested on MRS agar (Difco) using GasPak jars (BBL) at 30 °C. Motility was tested in MRS medium with 0.4% agar. Physiological characteristics (acid production, carbon-source utilization, enzyme activities, and biochemical features) were determined using the API 50CH, API ZYM, API 20E, and API 20 Strep galleries according to the manufacturer’s instructions.

**Keywords:** *Lactobacillus allii*; kimchi; lactic acid bacteria; novel species.

**Abbreviations:** ANI, average nucleotide identity; LAB, lactic acid bacteria; pheS, phenylalanyl-tRNA synthase alpha subunit; rpoA, RNA polymerase alpha subunit.

The GenBank/EMBL/DDBJ accession numbers of the complete genome sequences of strain WiKim39^T are CP019323 (chromosome) and CP019324 (plasmid).
instructions (bioMérieux). Catalase activity was determined by assessing the production of oxygen bubbles in 3% (v/v) aqueous hydrogen peroxide solution. Oxidase activity was measured using an Oxy-swab (bioMérieux) according to the manufacturer’s recommendations. For haemolysis testing, the bacteria were streaked on MRS agar containing 5% (w/v) sheep’s blood and incubated for 48 h at 30 °C. Tellurite tolerance tests were performed by supplementation with 0.04% K₂TeO₃ (Sigma-Aldrich). Lactic acid production was quantified using a DL-lactic acid assay kit (Megazyme International).

Cells of strain WiKim39ᵀ were rods with an average length of 0.6×1.8–2.5 μm. The strain was identified as a facultative anaerobe, and it grew at temperatures from 25 to 37 °C and at a pH from 4.5 to 9.0 with optimum growth at 30 °C and pH 6.5–7.0. No growth was observed at ≤20°C and ≤pH 4.0 or ≥40°C and ≥7% (w/v) NaCl 1⁻¹. Positive reactions were observed in tests for the production of acid from D-galactose, D-glucose, D-fructose, N-acetylglucosamine, amygdalin, arbutin, aesculin ferric citrate, salicin, D-cellobiose, D-maltose, D-lactose, D-sucrose, and gentiobiose. In addition, enzyme detection with an API zym kit was positive for alkaline phosphatase, esterase, leucine arylamidase, valine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, α-glucosidase, β-glucosidase, and N-acetyl-β-glucosaminidase. No esterase lipase, cystine arylamidase, trypsin, α-chymotrypsin, α-galactosidase, β-galactosidase, β-glucuronidase, α-mannosidase, or α-fucosidase activities were observed. Biochemical features were negative for nitrate and nitrite reduction; production of indole, H₂S, urease, pyrrolidonyl arylamidase, arginine dihydrolase; or positive for alkaline phosphatase, esterase, leucine arylamidase, pyrrolidonyl arylamidase, arginine dihydrolase; or positive for alkaline phosphatase, esterase, leucine arylamidase, pyrrolidonyl arylamidase, arginine dihydrolase; or positive for alkaline phosphatase, esterase, leucine arylamidase.

The complete genome of strain WiKim39ᵀ was sequenced using the PacBio RSII sequencing system (Pacific Biosciences) by Macrogen. The reads were assembled de novo using Hierarchical Genome Assembly Process version 3.0 (HGAP3.0) in SMRT analysis version 2.3.0 [22]. The complete genome sequence was annotated using the combined results from the automatic NCBI Prokaryotic Genomes Annotation Pipeline (PGAP).

The complete genome of strain WiKim39ᵀ consists of a circular 2 506 167 bp chromosome and one circular plasmid, totaling 2 534 178 bp. The chromosome contains 2427 predicted protein-coding genes (CDSs), four rRNA operons (5S rRNA, 16S rRNA and 23S rRNA), 67 tRNAs, and 3 non-coding RNAs. Strain WiKim39ᵀ contains 35.3 mol% G+C in its DNA, which is in the reported range of 31.93–57.02%.
for Lactobacillus species [23], and this value was similar to the value of 37.6 % for Lactobacillus nodensis DSM 19682T (AZDZ00000000). The complete genomes determined in this study have been deposited in the NCBI GenBank data-base under the accession numbers CP019323 (chromosome) and CP019324 (plasmid).

To evaluate the similarity between genome sequences, average nucleotide identity (ANI) values were analyzed between the strain and reported genomes using EzBioCloud as described by Moon et al. [24]. The strain showed ≤78.6 % ANI values relative to the Lactobacillus reference strains Lactobacillus nodensis DSM 19682T (AZDZ00000000) and

**Description of Lactobacillus allii sp. nov.**

*Lactobacillus allii* (a’l’i.i. L. gen. n. *allii* of garlic, of the botanical genus *Allium*, the source of scallion kimchi from which the type strain was isolated) cells are Gram-positive, catalase and oxidase-negative, facultatively anaerobic, and non-motile. Additionally, the cells are non-spore-forming rods, are 0.6×1.8–2.5 µm in size, and occur singly or in pairs. Colonies grown on MRS agar at 30 °C for 48 h are up to 1.0 mm in diameter, off-white, smooth, and round with rough surfaces. They are homofermentative; gas is not produced from glucose. The cells produce D- and L-lactic acid at a ratio of 52:48. Growth occurs at 25–37 °C and in the presence of 5 % NaCl but not in the presence of 7 % NaCl. Growth occurs at pH 4.5–9.0 but not at pH 3.5–4.0. Acid is produced from glucose. The cells produce D- and L-lactic acid at a ratio of 52:48. Growth occurs at 25–37 °C and in the presence of 5 % NaCl but not in the presence of 7 % NaCl. Growth occurs at pH 4.5–9.0 but not at pH 3.5–4.0. Acid is produced from glucose.

The cell-wall peptidoglycan type was determined by methods described previously [26]. Cellular fatty acid patterns were determined in cells from all reference strains and strain WiKim39T grown on MRSA plates at 30 °C for 48 h. The fatty acid methyl esters were extracted and analyzed according to the standard protocol of the Sherlock Microbial Identification System (MIS, MIDI Inc.). The fatty acid methyl ester mixtures were separated with an automated GC system (autosampler models 7890A and 7683B; Agilent) and identified using the BHIBLA database of the Microbial Identification Sherlock software package v6.3.

The peptidoglycan structure type of strain WiKim39T was A4α L-Lys-D-Asp (A11.31), which is the major type in most species of the closely related reference strains and the *L. alimentarius* – *L. farcininis* phylogenetic subgroup within the genus *Lactobacillus* [27]. The major cellular fatty acids contained by WiKim39T were C16:0 and C18:1ω9c. The fatty acid composition of WiKim39T was similar to that of *L. tucceti* KCTC 21005T, with small variations in the proportion, whereas the major fatty acids of the other reference strains were C16:0, C18:1ω9c, and C19:1 cyclo 9, 10 (Table 2). On the basis of its phenotypic, genotypic, and chemotaxonomic characteristics, strain WiKim39T can thus be distinguished clearly from the type strains of other species of the genus *Lactobacillus*, and the name *Lactobacillus allii* sp. nov. is proposed.

**Fig. 1.** Neighbour-joining phylogenetic tree based on 16S rRNA gene sequences showing the relationships of strain WiKim39T within the genus *Lactobacillus*. Filled circles represent identical branches that are present in phylogenetic consensus trees constructed using the neighbour-joining, maximum-parsimony, and minimum-evolution algorithms. Numbers at nodes indicate bootstrap values as percentages of 1000 replicates, and values >50 % are shown at branch points. *Lactobacillus delbrueckii* subsp. *delbrueckii* YIT 0080T was used as outgroup. Bar, 0.01 changes per nucleotide position.
Fig. 2. Neighbour-joining phylogenetic tree based on partial pheS (a) and rpoA (b) sequences showing the relationships between strain WiKim39\(^{T}\) and closely related species chosen as reference strains. Filled circles represent identical branches that are present in phylogenetic consensus trees constructed using the neighbour-joining, maximum-parsimony, and minimum-evolution algorithms. Numbers at nodes indicate bootstrap values as percentages of 1000 replicates, and values >50 % are shown at branch points. Lactobacillus delbrueckii subsp. delbrueckii LMG 6412\(^{T}\) was used as outgroup. Bar, 0.05 changes per nucleotide position.
