(Dated: 13 April 2011)

The propagation of surface electromagnetic waves along a uniform magnetic field is studied in a quantum electron-hole semiconductor plasma. A new forward propagating mode, not reported before, is found by the effect of quantum tunneling, which otherwise does not exist. In the classical limit ($\hbar \to 0$) one of the low-frequency modes is found similar to an experimentally observed one in n-type InSb at room temperature. The surface modes are shown to be significantly modified in the case of high-conductivity semiconductor plasmas where electrons and holes may be degenerate. The effects of the external magnetic field and the quantum tunneling on the surface wave modes are discussed.

PACS numbers: 52.35.-g, 52.30.Ex, 52.25.Xz, 52.35.Hr

The propagation of surface electromagnetic waves along an external magnetic field in conducting solids has been a topic of important research over the last forty years. In fact, there was excellent agreement between the theoretical predictions based on simple models and the experimental observations. In 1972, Baibakov and Datsko \cite{1} had experimentally observed a new low-frequency surface wave mode along a constant magnetic field in electron-hole (e-h) plasmas in n-InSb samples at room temperature. This new surface mode was, however, theoretically explained by Flahive and Quinn \cite{2} and later by Uberoi and Rao \cite{3} with the predictions of additional surface modes. In contrast to a single-component plasma, two additional characteristic frequencies, namely the plasma and the cyclotron frequencies of holes exist in e-h plasmas. Thus, new types of excitations may result into the propagation of surface waves with new interesting behaviors.

On the other hand, even though the particle number density in semiconductors is lower than that in metals, the high-degree of miniaturization of today’s electronic components opens up the possibility that the thermal de Broglie wavelength of charge particles may be comparable to or even larger than the spatial variation of the doping profiles. Thus, one could expect the typical quantum mechanical effects, such as tunneling to play important roles in electronic devices to be constructed in near future. A recent review of quantum collective phenomena and typical quantum effects on wave-particle and wave-wave interactions can be found in the literature \cite{4}. Furthermore, in the recent years there has been a considerable interest in the investigation of various surface wave modes in classical (see, e.g. Refs. \cite{5} \cite{12}) as well as in quantum plasmas (see, e.g. Refs. \cite{13} \cite{17}). However, most of these studies until now have been restricted to single-component magnetized or unmagnetized quantum plasmas.

In this paper, we investigate the propagation of electromagnetic surface waves at the e-h plasma-vacuum interface parallel to an applied magnetic field. We consider the quantum tunneling effect to be associated with the Bohm potential which provides a dispersion due to particle’s wave-like nature \cite{3}. In addition to a surface mode, which in the nonretarded limit ($k \gg \omega$) is given by

$$\omega \approx \left( 1 + k/\sqrt{1 + k^2 + 1/m\delta} \right)^{-1/2}$$

(in nondimensional form), where $k$ ($\omega$) is the wave number (frequency), $m$ is the electron to hole mass ratio and $\delta$ is the ratio of the hole to electron number densities, we find other surface modes with frequencies below the hole-cyclotron frequency as well as between hole and electron-cyclotron frequencies. Furthermore, a new quantum surface mode is found to exist as a forward propagating wave by the quantum tunneling effect. In the classical limit, $\hbar \to 0$, one of the low-frequency modes is found to have similar property with the experimentally observed wave in Ref. \cite{1}.

We consider a Cartesian geometry where the plane $x = 0$ separates the half-space $x > 0$ filled by a quantum plasma consisting of electrons and holes (to be denoted respectively by $\alpha = e$ and $\h$) and vacuum ($x < 0$). We also assume that the electron and hole densities are, in general, not equal \cite{18}. In a uniform magnetic field $\mathbf{B}_0 = B_0\hat{z}$, the dynamics of electrons and holes are governed by

\begin{equation}
\partial_t n_\alpha + \nabla \cdot \mathbf{v}_\alpha = 0, \tag{1}
\end{equation}

\begin{equation}
m \frac{\partial \mathbf{v}_e}{\partial t} = -(\mathbf{E} + \omega_{ce}\mathbf{v}_e \times \hat{z}) - \kappa \nabla n_e + \frac{\hbar^2}{4} \nabla \nabla^2 n_e, \tag{2}
\end{equation}

\begin{equation}
m \frac{\partial \mathbf{v}_h}{\partial t} = \mathbf{E} + \omega_{ch}\mathbf{v}_h \times \hat{z} - \sigma \kappa \nabla n_h + \frac{m\hbar^2}{4} \nabla \nabla^2 n_h, \tag{3}
\end{equation}

whereas the electromagnetic wave fields are described by the following Maxwell-Poisson equations.

\begin{equation}
\nabla \times \mathbf{E} = -\partial_t \mathbf{B}, \tag{4}
\end{equation}

\begin{equation}
\nabla \times \mathbf{B} = \mathbf{v}_h - \mathbf{v}_e/\delta + \partial_t \mathbf{E}, \tag{5}
\end{equation}

\begin{equation}
\nabla \cdot \mathbf{B} = 0, \tag{6}
\end{equation}

\begin{equation}
\nabla \cdot \mathbf{E} = n_h - n_e/\delta, \tag{7}
\end{equation}

where the number density $n_α$ and the velocity $v_α$ for α-species particle are normalized respectively by the equilibrium value $n_{α0}$ and $c_α$. Here $c_α$ may be defined as either $c_α = \sqrt{k_B T_α/m_α}$ for moderate densities (using, e.g., an isothermal equation of state) or $c_α = \sqrt{2k_B T_α/m_α}$ for relatively dense medium (where electrons and holes are degenerate and Fermi-Dirac pressure law pertaining to a three-dimensional zero-temperature Fermi gas is applicable) in which $T_α$ is the Fermi (thermodynamical) temperature of electrons or holes with $k_B$ denoting the Boltzmann constant. The electric and the magnetic fields $E$ and $B$ are respectively normalized by $m_α c_α \omega_{ph}/ε_0$ and $m_α c_ω \omega_{ph}/\sqrt{ε_0 μ_0}$.

Moreover, the space and the time variables are normalized by $c_α/\omega_{ph}$ and $ω_{ph}^{-1}$ respectively. Also, $ω_{pa} = \sqrt{n_0 e^2/ε_0 m_α}$ is the plasma frequency, $ω_{ce} ≡ eB_0/m_α ω_{ph}$ is the normalized cyclotron frequency, $m = m_α/m_π$ is the electron to hole mass ratio and $δ = n_β/n_α$. Furthermore, the quantum coupling parameter $H$ appearing in Eqs. 14 and 15 may be defined as $H = \sqrt{β ω_{pe}/k_B T_α}$ for classical thermal spread or $H = \sqrt{β ω_{pe}/2k_B T_α}$ for degenerate dense plasmas. In the latter case, which may be relevant for high-conductivity semiconductor plasmas, the temperature ratio will be related to the density ratio according to $σ ≡ T_F/k_B T_α = \delta^{2/3}/m$, where $k_B T_α$ is the usual Fermi temperature (classical thermal spread or relatively the dense medium in which electrons and holes are degenerate).

In what follows, we will find solutions that represent the surface waves propagating along the interface $x = 0$. To this end, we assume that the electromagnetic fields and the perturbed densities associated with the surface wave with the wave number $k$ and the frequency $ω (< ω_{ph})$ vary as $Ψ(x,y,t) = Ψ(x) e^{i(ky − ωt)}$. Thus, we obtain from Eqs. 11-13 and the wave equations for the density perturbations as

$$\partial_x^2 n_α − γ_α^2 n_α = 0,$$

where

$$γ_α = \left[ \left( k^2 β_2 + ν_e + \frac{1}{\delta} \right) \left( k^2 β_1 + ω_n + 1 − \frac{1}{\delta} \right) \right]^{1/2}$$

with $β_1 = σ κ + m H^2 k^2/4$, $β_2 = κ + H^2 k^2/4$, $ν_e = m(ω_n^2 − ω_π^2)$, $ω_n = ω_n^2 − ω_π^2$, $ν_e = ω_n^2 − ω_π^2$, $μ_e = 1/\delta$ and $μ_π = ω_π^2$. In obtaining Eq. 9, the very slow nonlocal variations are neglected, i.e., $∂^6/∂x^6$, $k^2 (∂^4/∂x^4)$ $< \partial^2/\partial x^2$ $\ll k^2$. In this approximation, the existence of some particular modes, e.g., degenerate or singular waves 19, not of current interest, is disregarded. Next, the equation for the magnetic field is

$$\partial_x^2 B − \alpha_p^2 B = 0,$$

FIG. 1. (Color online) The dispersion relation (20) in non-dimensional form is contour plotted to show different surface wave modes in the $k − ω$ plane (The case of non-degenerate plasmas). The modes labeled A’s, B’s, C’s are for $H = 0$ and those with labels Q’s are for nonzero $H$. The labels [A1, B1, C1, Q1]; the thin (red lines) and [A2, B2, C2, Q2]; the thick (blue) lines indicate the surface modes corresponding to $B_0 = 0.6 T$ and $B_0 = 1.6 T$ respectively. Other parameters are $m_α = 0.01 m_0$, $m_π = 0.4 m_0$, $T_α = T_π ≈ 300 K$, $n_{α0} = 1.35 × 10^{22} m^{-3}$ and $n_{π0} = 10^{22} m^{-3}$.

where $α_p = (1 + k^2 − ω^2 + 1/δ m)$ $^{1/2}$. The solutions of Eqs. 9 and 10 are then given by

$$n_α = A_α \exp(−γ_α x), \quad x > 0,$$

$$B = F_α \exp(α_v x), \quad x < 0,$$

$$B = F_α \exp(−α_p x), \quad x > 0,$$

where $α_v = \sqrt{k^2 − ω^2}$ is the decay variable of the wave into vacuum and $A_α, F_α$ are arbitrary constants. Using the Maxwell equations 14-16, the solutions for the electric field can be obtained as

$$E = R_α \exp(α_v x), \quad x < 0,$$

$$E = R_α e^{−γ x} + \sum_{α = e, h} (−α_α A_α(−γ_α x + i k y) e^{−γ_α x}, \quad x > 0,$$

where $R_α$ are arbitrary constants with $ε_e, h = ± 1$ and

$$γ = \left[ k^2 − ω^2 − \frac{ω^2}{ω_{ce}^2 − ω^2} − \frac{m_α ω^{2}_e}{m_α ω_{che}^2 − ω^2} \right]^{1/2},$$

$$λ_e = \left[ 1 + \frac{m_α ω_{che}^2}{ω_{che}^2 − ω^2} \left( \frac{H^2}{4} \left( γ_e^2 − k_e^2 \right) \right) \right] \times \left[ 1/γ_e^2 \right],$$

$$λ_h = \left[ 1 + \frac{m_α ω_{che}^2}{ω_{che}^2 − ω^2} \left( κσ − \frac{m_α H^2}{4} \left( γ_h^2 − k_h^2 \right) \right) \right] \times \left[ 1/γ_h^2 \right].$$

Surface waves are those solutions for which the wave number normal to the surface has negative imaginary
part, leading to an exponential decay away from the surface. Thus, in the above solutions \(11-15\) we have retained only those parts in both the regions which exponentially decay away from the interface. Next, we use the boundary conditions, namely (i) the tangential component of \(\mathbf{E}\) and \(\mathbf{B}\) are continuous at \(x = 0\), (ii) the normal component of the displacement vector is continuous at \(x = 0\), (iii) velocity components (along \(x\) axis) vanish for both electrons and holes (hot species), i.e. \(v_{ex} = v_{hx} = 0\) at \(x = 0\). Thus, we obtain a system of linear homogeneous equations which has nontrivial solutions only if the determinant of the resulting system vanishes. This leads to the following dispersion relation.

\[
\begin{align*}
\left[ \omega^2 \alpha_e + (\omega^2 - 1) \alpha_p \right] & \left[ \frac{\omega^2 \gamma_e - (\omega^2 - 1) \alpha_p}{\delta (\gamma^2_e - \gamma^2)} \left( \beta_2 + H^2 \gamma_e^2 / 4 \right) \right] \\
+ (2 \omega^2 - 1) & \alpha_e \left[ \frac{\omega^2 \gamma_h - (\omega^2 - 1) \alpha_p}{(\gamma^2_h - \gamma^2) \left( \beta_1 - mH^2 \gamma_h^2 / 4 \right)} \right] \\
& = 0, \quad (19)
\end{align*}
\]

where

\[
\begin{align*}
\Delta_e & = 1 + m \left( \frac{\omega^2 e^2}{\omega^2 - \omega^2} \right) + \frac{H^2 \gamma^2_e}{4}, \quad (20) \\
\Delta_h & = 1 + m \left( \frac{\omega^2 \gamma^2_h}{\omega^2 e^2 - \omega^2} \right) + \frac{mH^2 \gamma^2_h}{4}.
\end{align*}
\]

We note that the surface waves occur only if \(k > \omega\). The first factor of the dispersion equation \(19\) gives ordinary surface mode (as mentioned in the introduction) independent of the magnetic field and the quantum correction term, which decays with the wave number \(k\). However, it approaches a constant value \(\omega \approx 0.7\) in the limit \(k \gg \omega\). In order to analyze numerically the dispersion relation \(20\), we consider two different density regimes relevant for non-degenerate and degenerate plasmas. We consider the fixed parameters \(e_c = 0.01 m_0, m_h = 0.4 m_0, T_e = T_h = 300 K\), where \(m_0\) is the free electron mass. For non-degenerate particles (Figs. 1 and 2), we use the densities \(n_{e0} \sim 10^{22} m^{-3}\) as in Refs. \(1, 2\) and for degenerate electrons and holes we consider \(n_{e0} \sim 10^{26} m^{-3}\) (Fig. 3). In the latter, the thermal de Broglie wavelength \(\lambda_B\) is greater than the average inter-particle distance, i.e. \(n_{e0} \lambda_B^2 \sim 17 > 1\), and so quantum effect is no longer negligible. Thus, the typical quantum mechanical effects, e.g. tunneling will certainly play an important role in the modification and/or generation of a new dispersive surface mode. Notice that the quantum modified modes may not appear in the present case as we have disregarded the very slow nonlocal variations \(14, 15\), rather appears a new mode by the quantum force, which otherwise (i.e. in the limit \(h \rightarrow 0\)) does not exist.

In Figs. 1-3, the lines with labels \(A\)'s, \(B\)'s and \(C\)'s correspond to the classical \((H = 0)\) surface modes whereas those with labels \(Q\)'s are due to quantum tunneling effects. We find that there appear three different modes for \(H = 0\) whose frequencies lie in the regimes: \(\omega_{ch} < \omega < \omega_{ce}, \omega_{ch} < \omega \approx \omega_1 < \omega_{ce}\) and \(0 < \omega < \omega_{en}\), where \(\omega_1\) depends on the parameters to be chosen. In the latter, the low-frequency mode labeled \(A1\) or \(A2\) has the similar behaviors as experimentally observed in Ref. \(1\). Its slope increases with increasing the strength of the magnetic field and the wave phase speed tends to zero at a nonzero \(k = k_1\), i.e. the existence of surface wave at
parameters fixed) shows that the quantum mode appears in a smaller frequency domain at higher values of $K$.

To summarize, a new quantum surface mode at a plasma-vacuum interface is shown to appear by the inclusion of quantum mechanical (tunneling) effect in a magnetized electron-hole semiconductor plasma. Recent technological progress in the creation of smaller scales of plasma oscillations in electronic devices indicate that the thermal de Broglie wavelength can even be larger than the inter-particle distance of the charge carriers, and so quantum mechanical effects (tunneling) may no longer be neglected. We note that such surface mode due to quantum tunneling appears as a forward propagating wave up to a certain frequency below the hole plasma frequency. Furthermore, the phase speed of these waves strongly depends on the external magnetic field and the electron-hole concentration in the plasma. Apart from that several other low-frequency modes also appear in the limit $h \to 0$, one of which has similar behaviors with that experimentally observed mode in $n$-InSb at room temperature [1]. On the other hand, when quantum statistical effects are taken into consideration along with the quantum tunneling, specifically for high-conductivity semiconductors where electrons and holes are rather dense and may be degenerate, the quantum surface wave propagates in a different way in contrast to non-degenerate plasmas. The results may be useful for understanding the dispersion properties of new quantum surface waves in semiconductor plasmas, which can be observed experimentally in near future.

[18] At room temperatures the conductivity of intrinsic semiconductors in which electron and hole densities are equal may be relatively low. However, this can be enhanced by adding some impurities (doping) in the background plasma. Furthermore, in the case of $n$-type (extrinsic) semiconductors which were also used in the experiment of Ref. [1] as a sample, the electrons are considered to be major carriers.
