a nicola.pinamonti@desy.de

Abstract. In this paper we generalize the construction of generally covariant quantum theories given in [BFV03] to encompass the conformal covariant case. After introducing the abstract framework, we discuss the massless conformally coupled Klein Gordon field theory, showing that its quantization corresponds to a functor between two certain categories. At the abstract level, the ordinary fields, could be thought as natural transformations in the sense of category theory. We show that, the Wick monomials without derivatives (Wick powers), can be interpreted as fields in this generalized sense, provided a non trivial choice of the renormalization constants is given. A careful analysis shows that the transformation law of Wick powers is characterized by a weight, and it turns out that the sum of fields with different weights breaks the conformal covariance. At this point there is a difference between the previously given picture due to the presence of a bigger group of covariance. It is furthermore shown that the construction does not depend upon the scale $\mu$ appearing in the Hadamard parametrix, used to regularize the fields. Finally, we briefly discuss some further examples of more involved fields.

1 Introduction

The systematic analysis of quantization in terms of functors given by Brunetti, Fredenhagen and Verch [BFV03], opened an interesting new way to interpret the quantum field theory on curved spacetimes. With this new ideas, the expectation values of fields in different spacetimes can be compared in a mathematically rigorous way. Some interesting new applications have been developed following this line of thinking, we remind here the work of Buchholz and Schlemmer [BS07] and Schlemmer and Verch [SV08], where the authors deal consistently with expectation values of fields in different spacetimes. Another interesting use of similar ideas can be found in the derivation of local energy bounds in curved spacetime as performed by Fewster [Fe07]. The use of these concepts plays a central role in the development of a perturbative theory of quantum gravity, to this end we would like to remind the interesting paper of Brunetti and Fredenhagen [BF06].

A central role in the analysis performed in [BFV03] is played by the study of the isometric embeddings between different spacetimes and their interplay with the quantization procedure.
It was shown that the quantization of the massive Klein Gordon fields can be encompassed in the new scheme. Furthermore, the field itself and its Wick powers, as constructed by Hollands and Wald in [HW01, HW02, HW05], can be interpreted as a generally covariant quantum fields.

Here we would like to address the same problem in the case of field theories having a larger group of symmetry, namely the locally conformally covariant case. To this end we introduce the notion of generally conformally covariant fields by enlarging the abstract setup presented in [BFV03]. The idea of considering more complicated morphisms than isometries appeared for the first time in the work of Brunetti [Br04], we would like to follow similar line of reasoning.

We shall furthermore show that, despite the presence of quantum anomalies, there is a non trivial choice of the renormalization freedom\(^1\) that makes the conformally coupled Klein Gordon field and its Wick powers, conformally covariant in the abstract sense. At this point it seems interesting to remark that the requirement of being conformally covariant restricts the renormalization freedom usually present in the construction of these fields. Another interesting difference that arises in the case under investigation is that the transformations rules enjoyed by the Wick powers are characterized by the presence of a weight. Furthermore, the sum of Wick monomials with different weight breaks the conformal covariance.

The analysis performed in this paper allows to geometrically relate a larger class of spacetimes than in [BFV03], namely those that are locally connected by a conformal transformation. In this way it is possible, for example, to transplant observables (and states) from the de Sitter spacetime to the Minkowski one. This could be useful in the study of concepts like local equilibrium states [BOR02] in the case of conformally covariant theories as well.

The paper is organized as follows: at first we introduce the notion of locally generally conformal covariant quantum fields. The example of the massless conformally coupled scalar Klein Gordon field is studied in the second section, we shall present the transformation rule of the fundamental solutions and of the Hadamard parametrix in particular. The third section contains the analysis of the Wick powers. Some final comments and some further non trivial examples of more complicated fields are given in the fourth section. The appendix contains some technical computation used in the derivation of the results.

1.1. Categorial formulation of locally conformally covariant field theory. We are going to enumerate the relevant categories that will be used later for the formulation of a conformal quantum field theory in terms of a functor between certain categories. Before doing it, we introduce some small modifications to the locally covariant picture of quantum field theory presented for the first time in [BFV03], in order to adapt the formalism to include the case of conformal invariant theories. The key observation is that conformal invariant field theory should be invariant under a reacher group of transformations, namely the local conformal transformations. It is interesting to notice that such transformations share a lot of nice properties with isometries, the causal structure is preserved by such transformations in particular and this fact will play a central role later on. For a better formalization of these concepts we would like

---

\(^1\) A detailed analyses of the renormalization freedom can be found in the work of Hollands and Wald [HW01, HW05].
to introduce the notion of conformal embedding.

**Definition 1.1.** Consider two globally hyperbolic spacetime \((M_1, g_1)\) and \((M_2, g_2)\) then, a map \(\psi : M_1 \rightarrow M_2\) is called conformal embedding if it is a diffeomorphism between \(M_1\) and \(\psi(M_1)\) and if \(\psi\) is a conformal isometry, namely, the push forward \(\psi_*\) acts on the metric \(g_1\) in the following way: \(\psi_*g_1 = \Omega^{-2} g_2|_{\psi(M_1)}\) where \(\Omega\) is a strictly positive smooth function on \(\psi(M_1)\), called conformal factor.

In the following we shall consider the case of a conformal embedding \(\psi\) between two globally hyperbolic spacetimes \((M_1, g_1)\) and \((M_2, g_2)\) that preserves orientation and time orientation and such that the image \((\psi(M_1), g_2|_{\psi(M_1)})\) is also an open globally hyperbolic subset of \((M_2, g_2)\). We would like to remark that, under the given hypotheses, \(\psi\) preserves the causal structures of the spacetime\(^2\), mapping for example causal curves to causal curves and so on and so forth. The following action of weighted conformal transformations on test functions will play a distinguished role in the definition of the weight of the field.

**Definition 1.2.** Let \(\psi\) be a conformal embedding between \((M_1, g_1)\) and \((M_2, g_2)\) with conformal factor \(\Omega_\psi\) then, the weighted action on test functions \(\psi_*^{(\lambda)}\) is the map from \(C^\infty(M_1)\) to \(C^\infty(\psi(M_1))\) such that,

\[
\psi_*^{(\lambda)}(f)(x) := \Omega^{-\lambda}_\psi \cdot (f \circ \psi^{-1})(x).
\]

Where \(\lambda \in \mathbb{R}\) is called the weight of the map.

The previously given definition deserves some comments regarding its domain of definition and its inversion. While it is clear that \(\psi_*^{(\lambda)}\) can also be thought as acting on compactly supported smooth function \(\psi_*^{(\lambda)} : C^\infty_0(M_1) \rightarrow C^\infty_0(M_2)\), it is not true anymore considering smooth functions, that is because in general \(\psi(M_1)\) is a proper subset of \(M_2\) hence a smooth function \(f\) that is not compactly supported on \(M_1\) is not mapped to a smooth function in \(C^\infty(M_2)\). It is indeed impossible to extend uniquely \(\psi_*^{(\lambda)}(f)\) on \(M_2\) outside \(\psi(M_1)\). Despite the presence of these domain problems we would like to notice that \(\psi_*^{(\lambda)}\) is invertible either on \(C^\infty_0(\psi(M_1))\) or on \(C^\infty(\psi(M_1))\). The particular conformal embedding \(\psi : (M, g) \rightarrow (M, g')\) such that every \(p \in M\) is mapped to \(\psi(p) = p\), is called conformal transformation. Moreover, if the conformal factor \(\Omega_\psi\) of a conformal transformation is a constant then it is called rigid conformal transformation or rigid dilation.

We enumerate here the category used later on; these definitions are very similar to those given in [BFV03]. For this reason we shall stress, case by case, the differences we have to implement in order to encompass also the conformal transformations in framework.

**CLoc:** This is the category that encompasses all the geometric structures of the theory. The object of **CLoc** are all the four dimensional oriented and time oriented globally hyperbolic spacetimes. While the morphisms are all the conformal embeddings \(\psi : (M_1, g_1) \rightarrow (M_2, g_2)\) with the following additional properties, that are the same as previously given: (i) \((\psi(M_1), g_2|_{\psi(M_1)})\) is an open globally hyperbolic subset of \((M_2, g_2)\) and (ii) the morphisms

\(^2\)See the Appendix D of [Wa84] for more details.
preserve orientation and time orientation. The composition of morphisms is defined as the composition map of conformal embeddings in the usual way. The category $\text{CLoc}$ is an extension of the category $\text{Loc}$ given in [BFV03], in the sense that in $\text{CLoc}$ there is a larger class of morphisms than in $\text{Loc}$.

$\text{Alg}$: There is no need to modify the category of $\text{Alg}$ introduced in [BFV]. The object of $\text{Alg}$ are all the $C^*$-algebras built on a globally hyperbolic spacetime $(M, g)$, possessing unit elements, while their morphisms are the injective $*$-homomorphisms that preserve the unit; once again the composition descends from the usual composition map of $*$-homomorphism.

$\text{TAlg}$: The definition of a $\text{TAlg}$ follows easily the one of $\text{Alg}$; the difference is that the object of this category are taken to be only $*$-algebras with unit, instead of $C^*$-algebras. There is no modification between this and the previously given definitions.

$\text{Test}^\lambda$: The objects of this category are the sets of compactly supported smooth functions $C_0^\infty(M)$ on the spacetimes $(M, g)$. The morphisms are the weighted transformation $\psi^{(\lambda)}_*: M \to M'$ with $\lambda$ fixed in such a way that maps elements of $C_0^\infty(M)$ to elements of $C_0^\infty(M')$ as in the definition 1.2.

It seems interesting to notice that the categories $\text{Alg}$ and $\text{TAlg}$ are defined in the same way as on [BFV03, Br04], in a certain sense the algebraic formulation of quantum field theory is already suitable to describe conformal transformations. Furthermore the scaling transformations have already been considered as geometric morphisms in the work [Br04].

1.2. Quantum Conformal Field theory as a Functor and Conformal fields as Natural transformations. We are now in place to define the locally covariant conformal quantum field as a functor between the two categories $\text{CLoc}$ and $\text{Alg}$, such that the object of $\text{CLoc}$ are mapped into the object of $\text{Alg}$ whereas the morphisms $\psi$ of $\text{CLoc}$ are mapped into the morphisms $\alpha_\psi$ of $\text{Alg}$, in such a way that the following diagram commutes

$$(M, g) \xrightarrow{\psi} (M', g')$$

$\begin{array}{ccc}
A(M, g) & \xrightarrow{\alpha_\psi} & A(M', g') \\
\downarrow & & \downarrow \\
\alpha_\psi \circ \alpha_\psi' & = & \alpha_{\psi \circ \psi'} \\
\alpha_1_M & = & \mathbb{I}_{A(M)}
\end{array}$$

and the following compositions property holds:

$$\alpha_{\psi} \circ \alpha_{\psi'} = \alpha_{\psi \circ \psi'} , \quad \alpha_{1_M} = \mathbb{I}_{A(M)} .$$

The same construction can be repeated substituting the category $\text{Alg}$ with $\text{TAlg}$.

Despite the meaningfulness of the previously given definition and the presence of examples of the given framework, it is not at all clear if observables with a certain physical meaning in a

---

3The requirement of global hyperbolicity for $\psi(M_1)$ is equivalent to the requirement of causal convexity of $\psi(M_1)$ in $M_2$. In other words every causal curve with endpoints in $\psi(M_1)$ has to lie inside $\psi(M_1)$ too.
spacetime are mapped to observables with the same meaning, on the other spacetime. In general this is indeed not the case and it is precisely because of this problem that the ordinary fields needs to be introduced in an alternative way. In the picture we are going to introduce, they will assume the particular meaning of natural transformations between categories.

To this end it is useful to consider the set of weighted test functions $\mathcal{D}^\lambda$ as a functor between $\text{CLoc}$ and $\text{Test}^\lambda$. More precisely let's indicate by $\mathcal{D}^\lambda(M, g)$ the category whose elements are the sets of compactly supported smooth functions $C^\infty_0(M)$, and the morphisms $\alpha^\lambda_\psi$ between these sets are defined by means of the weighted action on test functions as defined in [1.2]. Clearly $\mathcal{D}$ can also be seen as a functor between the category of $\text{CLoc}$ to $\text{Test}$. We are now ready to introduce the notion of conformal quantum field as a natural transformation between two functors.

**Definition 1.3.** A field $\Phi^\lambda_{(M, g)}$ of weight $\lambda$ is a linear transformation between the functor that realizes the test functions $\mathcal{D}^{d-\lambda} : (M, g) \to \mathcal{D}^{d-\lambda}(M, g)$ and the functor that realizes the topological algebras $A : (M, g) \to A(M, g)$ such that the following diagram commutes

$$
\begin{array}{ccc}
\mathcal{D}^{d-\lambda}(M, g) & \xrightarrow{\Phi^\lambda_{(M, g)}} & A(M, g) \\
\psi^{(4-\lambda)} \downarrow & & \downarrow \alpha^\lambda_\psi \\
\mathcal{D}^{d-\lambda}(M', g') & \xrightarrow{\Phi^\lambda_{(M', g')}} & A(M', g')
\end{array}
$$

The preceding definition can be written more explicitly by means of the following conformal covariance property:

$$
\alpha^\lambda_\psi(\Phi^\lambda_{(M, g)}(f)) = \Phi^\lambda_{(M', g')}(\psi^{(4-\lambda)}(f)).
$$

Where $\psi^{(\lambda)}(f)$ is defines as a weighted transformation as given in the definition [1.2]. We call $\lambda$ the weight of the field $\Phi^\lambda$.

The difference between the weight in the test functions and the weight in the fields can be understood taking into account the transformation rule enjoyed by the volume form. Under a conformal embedding $\psi : (M, g) \to (M', g')$,

$$
\sqrt{g'(\psi(x))} \Omega^4(\psi(x)) = \sqrt{g(x)}
$$

where $g$ stands for the determinant of the metric.

As a consequence of the given definitions, linear combinations of fields with different weight are not conformally covariant fields. Precisely at this point there is a great difference with what was addressed in [BFV03], where also the linear combinations of fields with different “weights” were taken into account.

## 2 The model: Free conformal invariant scalar field.

In this section we present a model that shows the previously presented abstract structure. We shall consider the massless conformally coupled scalar field theory. Just to fix some notation
let’s remind that the classical equation of motion of the conformal Klein Gordon scalar field $\varphi$ on a spacetime $(M, g)$ is

$$P_g = -\Box_g + \frac{1}{6} R_g, \quad P_g \varphi = 0,$$

(1)

where $\Box_g$ is the d’Alambert operator constructed out of the metric $g$ and $R_g$ is the Ricci scalar of the metric $g$. We start our analysis with the study of the interplay between conformal transformations, the fundamental solutions and the microlocoal spectral condition [Ra96, BFK96].

2.1. Conformal transformation of the fundamental solutions. Let us start recalling the transformation law satisfied by the operator $P_g$ under conformal embeddings.

Lemma 2.1. Let $\psi$ be a conformal embedding of $(M_1, g_1)$ into $(M_2, g_2)$, consider the corresponding weighted transformations $\psi^{(1)}$ and $\psi^{(3)}$ of test functions thought as mappings from $C^\infty_0(M_1) \to C^\infty_0(\psi(M_1)) \subset C^\infty_0(M_2)$. The following equivalence holds for every $f$ in $C^\infty_0(M_1)$:

$$P_{g_2}(\psi^{(1)}(f)) = \psi^{(3)}(P_{g_1}(f)).$$

(2)

Proof. Because of the support properties of $f$ we know that the supports of the following smooth functions, $\psi^{(1)}(f)$ and $\psi^{(3)} \circ P_{g_1}(f)$, are contained in $\psi(M_1)$. Hence we can restrict our attention to the image of $M_1$ under $\psi$, namely to the spacetime $(\psi(M_1), g_1)$. Furthermore the conformal embedding $\psi$ becomes a conformal isometry if restricted to $\psi(M_1)$, and the proof of that proposition descends straightforwardly by means of a direct computation (a detailed analysis is contained in the appendix D of Wald’s book [Wa84]).

We can relax the hypotheses written above and use as test functions only the smooth functions. In this case the equivalence (2) works if restricted to the image $\psi(M_1) \subset M_2$. Another important extent of the transformation law of the wave operator $P_g$ we would like to stress is its interplay with weighted test functions. Actually, because of the presence of the conformal factor in the transformation law of the operator defining the equations of motion we have that $P_g$ maps test functions of weight 1 into test functions of weight 3.

In a globally hyperbolic spacetime $(M, g)$, the advanced / retarded fundamental solutions $\Delta^\pm$ of the partial differential equation $P_g \varphi = 0$ are the unique maps from $C^\infty(M)$ to $C^\infty(M)$ that enjoy the following properties $P_g \Delta^\pm f = f$ and the domains of $\Delta^\pm f$ are contained in the causal future / past of the support of $f$ respectively $\text{supp} \Delta^\pm(f) \subset J^\pm(\text{supp} f)$. For the issues regarding the uniqueness see [BGP07].

Let us study the transformation law enjoyed by the fundamental solutions under conformal embeddings and hence by the causal propagator.

Lemma 2.2. Let $\psi$ be a morphism in $\text{CLoc}$, hence $\psi$ is a conformal embedding between $\psi : (M, g) \to (M', g')$, let $\Delta^\pm$ and $\Delta'^\pm$ be the uniquely defined advanced/retarded fundamental
solutions of $P_g$ and $P_{g'}$. Consider the following operators from $C_0^\infty(\psi(M))$ to $C^\infty(\psi(M))$:
\[
\Delta_\pm^g := \psi^{(1)} \circ \Delta_\pm \circ \psi^{-1}_\pm
\]
then $\Delta_\pm^g$ are the uniquely defined advanced / retarded fundamental solutions of $P_g$ in $(\psi(M), g')$. Furthermore $\Delta_\pm^g = \chi(\psi(M)) \Delta_\pm |_{C_0^\infty(\psi(M))}$, where $\chi(\psi(M))$ is the characteristic function of $\psi(M)$.

Proof. $(\psi(M), g')$ is a global hyperbolic subspace of $(M', g')$, then, in order to show that $\Delta_\pm^g$ are the advanced / retarded fundamental solutions of $P_{g'}$ in $(\psi(M), g')$, we have to check two properties, the first one is that $P_{g'} \Delta_\pm^g f = f$ and the other one is that the support of $\Delta^g_\pm(f) \subset J^\pm(supp f)|_{\psi(M)}$ for every $f$ in $C_0^\infty(\psi(M))$. First of all, consider the following chain of equalities valid in $\psi(M)$ for every $f' \in C_0^\infty(\psi(M))$ and $f = \psi^{-1}_\pm(1)$:
\[
f' = \psi^{(3)}_\pm(f) = \psi^{(3)}_\pm \circ P_g(\Delta_\pm f) = P_{g'} \circ \psi^{(1)}_\pm(\Delta_\pm f) = P_{g'} \left( \Delta_\pm^g \circ \psi^{(3)}_\pm(f) \right)
\]
The second step is to check that the domain property are preserved by $\psi$. Nonetheless the properties of $\psi$ assure the validity of the following chain of inclusions.
\[
supp \Delta_\pm^g f' = \psi(supp \Delta_\pm f) \subset \psi(J^\pm(supp f)) \subset J^\pm(\psi(supp f))
\]
in $\psi(M)$. Furthermore, $\psi$ maps causal curves into causal curves preserving the orientation and from this it descends the last inclusion. □

The causal propagator $E$ is defined as the advanced minus retarded fundamental solution $E = \Delta_+ - \Delta_-$, it is a distribution on compactly supported smooth functions uniquely defined in a globally hyperbolic spacetime once $P_g$ is given. It can be seen as map form $C_0^\infty(M)$ to $C^\infty(M)$ namely the set of solutions of $P_g \phi = 0$.

Knowing the interplay between advanced, retarded fundamental solutions and conformal embeddings, we can derive straightforwardly the way in which the causal propagator $E$ transforms under conformal transformation, i.e.

**Lemma 2.3.** Let $\psi$ be a morphism in $\mathcal{C}_{\text{Loc}}$ between the two elements $(M, g)$, $(M', g')$ of $\mathcal{C}_{\text{Loc}}$, then $\chi(\psi(M))E'(\psi^{(3)}_\pm(f)) = \psi^{(1)}_\pm(E(f))$ for any $f \in C_0^\infty(M)$.

The two point functions of Hadamard type play a distinguished role in the formulation of a quantum field theory in curved spacetime [KW91]. From the work of Radzikowski [Ra96] and Brunetti, Fredenhagen and Khöler [BFK96] we know that an Hadamard two-point function is characterized by the microlocal spectral condition. Hence we shall say that a two-point distribution $\omega_2$ is of Hadamard type if its antisymmetric part corresponds to the causal propagator and if it satisfies the microlocal spectral condition, which means that the wave front set of $\omega_2$ has a certain form:

$$\text{WF}(\omega_2) = \{(x_1, k_1, x_2, k_2) \in T^*M \setminus \{0\}| (x_1, k_1) \sim (x_2, k_2), k_1 \in V_+ \}, \quad (3)$$
where \((x_1, k_1) \sim (x_2, k_2)\) if it exists a null geodesics \(\gamma[0, a] \to M\) such that \(\gamma(0) = x_1\) and \(\gamma(a) = x_2\) and \(k_1\) is the cotangent, coparallel vector to the geodesic at \(x_1\) while \(k_2\) is equal to the parallel transport along \(\gamma\) of \(-k_1\) on \(x_2\). The next preliminary task we have to accomplish is to give the transformation rule for the Hadamard two-point function under conformal embeddings. While we have already seen that the causal propagator satisfies an homogeneous transformation rule we would like to see what happens to the symmetric part of an \(\omega_2\) of Hadamard type.

**Lemma 2.4.** Let \(\psi\) be a morphism in \(\mathrm{CLoc}\) from \((M, g)\) to \((M', g')\) and \(\omega_2\) a distribution on \(C^\infty_0(M \times M)\) that satisfy the microlocal spectral condition then, consider

\[
\omega_2^\psi(f, g) := \omega_2(\psi_s^{-1}f, \psi_s^{-1}g).
\]

\(\omega_2^\psi\) is a distribution on \(C^\infty_0(\psi(M)^2)\) and it satisfy the microlocal spectral condition on \((\psi(M), g')\).

**Proof.** Since \(\psi_s^{(3)}\) is a smooth invertible map from \(C_0^\infty(M)\) to \(C_0^\infty(\psi(M))\), \(\omega_2^\psi\) is a distribution. Let us analyze its wave front set of \(\omega_2^\psi\) in \((\psi(M), g')\); the definition of wave front set does not depend on the metric \(g'\), we have simply to analyze the relation between \(M\) and \(\psi(M)\). Since the \(\psi_s^{(3)}\) is smooth and invertible, and since \(\psi\) is a diffeomorphisms we can immediately conclude that \((x_1, k_1, x_2, k_2)\) is an element of \(\mathrm{WF}(\omega_2^\psi)\) if and only if \((\psi^{-1}(x_1), \psi_s^{-1}(k_1), \psi^{-1}(x_2), \psi_s^{-1}(k_2))\) \(\in (\mathrm{WF}(\omega_2))\). Here \(\psi_s^{-1} : T_{(\psi(x))}\psi(M)^* \to T_xM^*\) defined in the standard way. We have to show that \((x_1, k_1) \sim (x_2, k_2)\) in \((\psi(M), g')\). To this end we are seeking for a future directed null geodesic \(\gamma'\) in \(\psi(M)\) whose extreme points are \(x_1\) \(x_2\) and whose cotangent vector in \(x_1\) is \(k_1\) and in \(x_2\) is \(-k_2\). Notice that, having \((\psi^{-1}(x_1), \psi_s^{-1}(k_1)) \sim (\psi^{-1}(x_2), \psi_s^{-1}(k_2))\) in \((M, g)\), it exists a future directed null geodesics \(\gamma\) with such properties in \((M, g)\). Because of the properties of the conformal embedding, \(k_1\) and \(k_2\) are also null vectors in \((\psi(M), g')\). Since \(\psi\) is an orientation and time orientation preserving conformal embedding, \(\gamma' = \psi(\gamma)\) turns out to be also future null geodesics in \(\psi(M)\), furthermore, let \(\lambda\) and \(\lambda'\) be the affine parameters of \(\gamma\) and of \(\psi(\gamma)\), then \(\frac{d\lambda'}{d\lambda} = c\Omega^2\) where \(c\) is a constant and \(\Omega\) is the conformal factor of \(\psi\). Notice that if \(\psi_s^{-1}k_1\) is a cotangent vector of \(\gamma\) in \(\psi^{-1}(x_1)\), \(k_1\) has to be the cotangent vector of \(\psi(\gamma)\) in \(x_1\), the same also holds for \(-k_2\) in \(x_2\). Finally, since the orientation is preserved by \(\psi\), the thesis turns out to be proved. \(\square\)

The singular structure of an Hadamard two point function, called Hadamard parametrix, is fixed [KW91], to proceed with our analysis it will be useful to analyze it in more details. The Hadamard parametrix \(H\) has the following expansion in a small geodesically convex neighborhood containing the points \(x\) and \(y\):

\[
H(x, y) = \frac{1}{8\pi^2} \left( \frac{u(x, y)}{\sigma_\epsilon(x, y)} + v(x, y) \log \frac{\sigma_\epsilon(x, y)}{\mu^2} \right) \quad (4)
\]

where \(u\) and \(v\) are certain smooth functions that depend only on the geometry of the spacetime \((M, g)\), once the equations of motion are chosen and \(\sigma_\epsilon = \sigma + i(T(x) - T(y))\epsilon + \epsilon^2/2\), where \(T\) is any time function [KW91] and \(\sigma\) is half of the squared geodesical distance between \(x\) and \(y\), taken with sign. We shall give further details on local construction of \(u\) and \(v\) in the appendix.
The Hadamard parametrix depends on the dimensional parameter $\mu$, we shall fix this parameter once and for every spacetime in $\text{CLoc}$. Finally we would like to analyze the difference of the singular structures in the sense of the following lemma.

**Lemma 2.5.** Let $\psi$ be a morphism in $\text{CLoc}$ between the two elements $(M,g)$, $(M',g')$. Let $H$ and $H'$ be the Hadamard parametrix respectively on two geodesically complete neighborhood $\mathcal{O}$ of $M$ and $\mathcal{O}'$ of $\psi(M)$ such that $\mathcal{O}' \subset \psi(\mathcal{O})$ then

$$H(\psi^{-1}(f),\psi^{-1}(g)) - H'(f,g) = \int_{\mathcal{O}' \times \mathcal{O}'} f(x,y) A(x,y) g(y) \, d\mu_{g'}(x) d\mu_{g'}(y)$$

where $A(x,y)$ is a smooth symmetric function on $\mathcal{O}' \times \mathcal{O}'$ and $f,g \in C^\infty_0(\mathcal{O}' \times \mathcal{O}')$. Furthermore, in general it is non vanishing, and its coinciding point limit is

$$A(x,x) = \frac{1}{(12\pi)^2} \left( R_g(\psi^{-1}(x)) - \Omega_x^2(\psi^{-1}(x)) \right),$$

where $\Omega_{\psi}$ is the conformal factor corresponding to $\psi$.

**Proof.** The distribution $H$ satisfy the microlocal spectral condition and its antisymmetric part corresponds to the causal propagator hence, also because of the preceding lemma,

$$H^{\psi}(f,g) := H(\psi^{-1}(f),\psi^{-1}(g))$$

is of Hadamard type in $(\psi(M),g)$ too. From this property it is clear that $H^{\psi} - H'$ must be a smooth function. In the equation (11) of the appendix we have shows that $A(x,x)$, has precisely the given form, hence, since $A(x,y)$ is a smooth function it cannot vanish in general. Finally, because of the lemma 2.3 the causal propagator in $(M,g)$ is mapped to the causal propagator in $(\psi(M),g)$. Since the antisymmetric part of $H$ correspond to the causal propagator, it descends that the antisymmetric part of $A$ must vanish. \(\square\)

We would like to remark that $A(x,x)$ does not depend upon the dimensional parameter $\mu$ present in the short distance expansion of the Hadamard parametrix (1).

### 2.2. Quantization as a functor.

In [BFV03] it was shown that the quantization in terms of $C^*$ algebras $\mathfrak{A}(M,g)$ generated by the Weyl operators of the Klein Gordon field correspond to a functor $\mathfrak{A}$ from the category of isometrically related manifolds $\text{Loc}$ to the category $\text{Alg}$. We would like to briefly show that in the case of massless conformally coupled Klein Gordon field the functor $\mathfrak{A}$ can be extended as a functor between $\text{CLoc}$ and $\text{Alg}$ as described in the section 1.2. The difference between what we are considering here and the previously given picture [BFV03] is that in the definition of $\text{CLoc}$, we have admitted conformal embeddings as morphisms between the same elements of $\text{Loc}$ too. Hence we have simply to check the covariance of $\mathfrak{A}$ with respect to the larger group of morphisms of $\text{CLoc}$. In the sense of the discussion presented in section 1.2 we have to show that being $\psi : (M,g) \rightarrow (M',g')$ a conformal embedding in $\text{CLoc}$ there exists a corresponding morphisms $\alpha_{\psi} : \mathfrak{A}(M,g) \rightarrow \mathfrak{A}(M',g')$ such that $\mathfrak{A}(\psi(M,g)) = \alpha_{\psi}(\mathfrak{A}(M,g)).$
We shall skip many details that can be easily reconstructed knowing the results of [Di80, BFV03]. For our purpose it will be sufficient to know that the morphism $\alpha_\psi$ can be straightforwardly constructed once a symplectic map between the two symplectic spaces $(S(M, g), \sigma)$ and $(S(M', g'), \sigma')$ is given. To be more precise let us analyze the construction of $(S(M, g), \sigma)$. Using the causal propagator and the differential operator defined above we can construct the set of wavefunctions $S$ as follows:

$$S(M, g) := E(C^\infty_0(M)).$$

$S(M, g)$ can be equipped with a symplectic form defined in the following way. Let $\varphi_f = Ef$ then, since the spacetime $(M, g)$ is globally hyperbolic, consider the following non degenerate symplectic form

$$\sigma(\varphi_f, \varphi_g) = \int_\Sigma (\varphi_f \partial_\alpha \varphi_g - \varphi_g \partial_\alpha \varphi_f) n^\alpha d\mu_{\Sigma} = \int f(Eg) d\mu_{g}$$

where $\Sigma$ is a Cauchy surface, moreover $\sigma$ is independent on the particularly chosen Cauchy surface $\Sigma$. $n$ is the unit vector normal to $\Sigma$, $\mu_{g}$ is the volume element induced by the metric $g$, and $\mu_{\Sigma}$ is the volume element restricted to the Hypersurface $\Sigma$.

We already know that for every isometric embedding $\psi_0 : (M, g) \to (M', g')$ it exists a symplectic map from $(S(M, g), \sigma)$ to $(S(M', g'), \sigma')$. A similar symplectic map exists considering a conformal embedding $\psi : (M, g) \to (M', g')$. In fact, from the transformation properties of the causal propagator seen in the lemma 2.3 we have that for every $\varphi_1$ and $\varphi_2$ in $S(M, g)$

$$\sigma'(\psi^{(1)}(\varphi_1), \psi^{(1)}(\varphi_2)) = \sigma(\varphi_1, \varphi_2).$$

It is now a simple task to construct the automorphism between $\alpha_\psi$ of $\mathfrak{A}(M, g)$ to $\mathfrak{A}(M', g')$ in the same way as in [BFV03]. Hence $\mathfrak{A}$ can be promoted as conformally covariant functor.

3 Fields as natural transformations

In order to build more interesting examples it is important to have an algebra of local observables that encompasses more complicated objects as the powers of the fields and the component of the stress tensor. We shall here remind the construction of the algebra of field as presented in the book [Wa94] and then we would like to show that that scalar field is a natural transformation between two functors indeed.

3.1. The CCR algebra. We would like to follow the algebraic approach so the starting point is the abstract $*$--algebra $\mathcal{A}(M, g)$ generated by the identity $\mathbb{1}$ and the smeared quantum fields $\varphi(f)$, where $f$ is a test function (smooth compactly supported function denoted by $\mathcal{D}(M)$). Furthermore the abstract fields $\varphi(f)$ must satisfy the following further requirements

(i) $\varphi(\alpha_1 f_1 + \alpha_2 f_2) = \alpha_1 \varphi(f_1) + \alpha_2 \varphi(f_2)$, where $\alpha_1, \alpha_2 \in \mathbb{C}$;

(ii) $\varphi(f)^* = \varphi(\overline{f})$;
(iii) \( \varphi(P_g f) = 0 \);
(iv) \( \varphi(f_1)\varphi(f_2) - \varphi(f_2)\varphi(f_1) = iE(f_1, f_2)I \),

where, \( E \) is the causal propagator of the massless conformally coupled Klein Gordon field, whose equation of motion is given by the operator \( P_g \) given in [1]. The sets of \( \mathcal{A}(M, g) \) with the algebraic morphisms form a category \( \mathcal{T}_{\text{Alg}} \). We would like to show that the abstract field \( \varphi \) can be interpreted as a natural transformation between that category and \( \mathcal{T}_{\text{Test}}^3 \).

**Proposition 3.1.** \( \mathcal{A} \) is a functor between the two categories \( \mathcal{T}_{\text{Test}}^3 \) and \( \mathcal{T}_{\text{Alg}} \), in fact: to every \((M, g)\) it is possible to associate \( \mathcal{A}(M, g) \) and be \( \psi \) a conformal embedding between \((M, g)\) and \((M', g')\) \( \mathcal{A}(\psi) \) is defined as the morphism that acts on the fields in the following way

\[
\alpha_\psi(\varphi(f_1) \ldots \varphi(f_n)) := \varphi'(\psi^{(3)}(f_1) \ldots \psi^{(3)}(f_n)) ,
\]

where \( \varphi, \varphi' \) are the fields that generate \( \mathcal{A}(M, g) \) and \( \mathcal{A}(M', g') \) respectively.

The proof of the present proposition descends form the definitions given above, from the transformation rules of the causal propagator and from the composition rules of the morphisms between two algebras. Moreover, exploiting the definition of \( \mathcal{A} \) and \( \mathcal{D} \) and using (5) for one single field, we also have the following proposition

**Proposition 3.2.** The scalar field \( \varphi \) is a natural transformation between the category \( \mathcal{T}_{\text{Test}}^3 \) and \( \mathcal{T}_{\text{Alg}} \) and hence it is a locally covariant conformal field of weight 1.

The difference in the weights between the field and the test functions can be understood exploiting the present heuristic representation of the field

\[
\varphi(f) := \int_M \varphi(x)f(x)\,d\mu_g ,
\]

and considering the transformation rule enjoyed by the measure \( \mu_g \) under conformal transformations.

### 3.2. Extension to the local algebra of fields and Wick monomials.

As shown in [DF01, HW01], in order to study the Wick monomials we have to extend the algebra \( \mathcal{A}(M, g) \) to a bigger one, that we shall indicate as \( \mathcal{W}(M, g) \). In this respect we follow the notation and construction introduced in [HW01] referring to that paper for technical details. Essentially the normal ordered fields, when evaluated on states satisfying the microlocal spectral condition, turn out to be distribution with a certain wavefront set. We can then smear them with more singular objects, namely the distributions on compactly supported smooth functions characterized by a certain wavefront set. The normal ordering prescription plays a distinguished role in this construction, we would like to remind its definition. The normal ordering with respect to the Hadamard singularity \( H \) (where a unit of measure \( \mu \) is chosen) is defined as follows

\[
: \varphi_n(x_1) \ldots \varphi(x_n) :_H := \frac{\delta^n}{i^n \delta f(x_1) \ldots \delta f(x_n)} \exp \left( \frac{1}{2} H(f \otimes f) + i\varphi(f) \right) \bigg|_{f=0} .
\]

11
The algebra $A(M,g)$ can now be enlarged allowing the smearing by more singular object then smooth functions in $C_0^\infty(M^n)$. In particular, let us consider the following set

$$\mathcal{T}^n(M) := \{ t \in \mathcal{D}'(M), t \text{ symm.}, \text{supp}(t) \text{ is compact}, \text{WF}(t) \cap V_+ \cup V_- = \emptyset \} ,$$

where $V_\pm$ are the forwards or backwards lightcones in $T^*M$ whose tip $x$ is in $M$. The requirement on the wave front set of the elements of $\mathcal{T}^n(M)$ is introduced in such a way that fields smeared by the distribution $t \in \mathcal{T}^n(M)$ can be unambiguously tested on states satisfying the microlocal spectral condition. For a more complete analysis on the subject we refer to the papers [BF00, HW01]. The algebra $W(M,g)$ can now be defined as the $*$-algebra generated by the elements defined as in (6) smeared by $t \in \mathcal{T}^n(M)$.

**Remark:** It can be shown combining the results in [BF00, HW01] that the algebra constructed in that way is independent on the choice of the Hadamard two point function $H$. In other words, substituting $H$ in the definition of the normal ordering with another two point distribution with the same singular structure, gives a set of generators of an isomorphic algebra. Part of this freedom is encoded in the choice of the unit length $\mu$. It is in any case possible to add a smooth symmetric function to $H$ without really changing the $*$-algebra $W(M,g)$.

We are now ready to study the Wick monomials that are defined as the normal ordered products of fields smeared by some special test distribution. More precisely, suppose to have a smooth function with compact support $C_0^\infty(M)$ then a Wick monomial $\varphi^n(f)$ of order $n$ can be defined as follows:

$$: \varphi^n :_H (f) := \int : \varphi(x_1) \ldots \varphi(x_n) :_H t_f(x_1, \ldots, x_n) \, d\mu_g(x_1) \ldots d\mu_g(x_n)$$

where $t_f(x_1, \ldots, x_n)$ is $f(x_1)\Delta(x_1, \ldots, x_n)$ and $\Delta$ is the diagonal distribution $\Delta(x_1, \ldots, x_n) = \delta(x_1, x_2) \ldots \delta(x_{n-1}, x_n)$.

The Wick powers defined in that way satisfy certain interesting properties, in particular they turn out to be locally covariant field in the sense of [BFV03]. Another important extent showed by $: \varphi^k :_H$ is the almost homogeneous scaling under rigid dilations, where the non homogenous term is logarithmic in the scaling parameter. Hollands and Wald have used an axiomatic approach, i.e., they have promoted these and other physically motivated properties to a set of axioms that every reasonable definition of Wick powers should satisfy. In [HW01], they have furthermore shown that, the previously given definition for $\varphi^k$ is the unique one that satisfies the axioms up to the following renormalization freedom

$$\tilde{\varphi}^k(x) = \varphi^k(x) + \sum_{i=1}^{k-2} C_i(x) \varphi^i(x)$$

where $C_i(x)$ are classical fields depending on the parameter of the Lagrangian, and on the metric tensor, furthermore it is required that $C_i$ scale homogeneously under rigid dilation while the total field $\varphi^k$ scales almost homogeneously, where the non homogeneous term must be of logarithmic type in the coupling scaling parameter. Hence, it is not possible to get rid of this non
homogeneous logarithmic scaling behavior by a suitable choice of the renormalization constants \( C_i(x) \).

3.3. Wick monomials and conformal covariance. It is known that the Wick monomials previously defined are locally covariant quantum field in the sense of the analysis performed in [BFV03]. Here we would like to see if these fields are also locally conformal covariant. Let’s start our discussion analyzing the simplest case of \( \varphi^2(x) \). Here the freedom (8) consists of the following redefinition

\[
\varphi^2_\alpha(x) =: \varphi^2 :H (x) + \alpha R(x)
\]

where \( R \) is the scalar curvature and \( \alpha \) is a constant. An interesting observation is the fact that both \( \varphi^2 :H (x) \) and \( \varphi^2_\alpha(x) \) scale homogeneously under rigid dilations, as can be seen from the transformation rules of the scalar curvature and the Hadamard singularity. Let \( H_g \) be the Hadamard singularity in the spacetime \((M, g)\), usually under rigid scaling \( \lambda \) it should transform in the following way

\[
\lambda^{-2}H_{\lambda^{-2}g}(x, y) = H_g(x, y) + v_g(x, y) \log \lambda^2,
\]

notice that in the case under consideration \( v_g(x, x) = 0 \), as can be seen from the appendix. Furthermore, \( R_g \) transforms homogeneously under rigid rescaling too

\[
\lambda^{-2}R_{\lambda^{-2}g} = R_g,
\]

hence the Wick monomial (9) transforms homogeneously under rigid dilation.

The second step in the analysis consists of testing \( \varphi^2_\alpha \) under local transformation. Let \( \psi \) be a conformal transformation from \((M, g)\) to \((M, g')\), then, taking into account the transformation rule of the Hadamard singularity \( H \) as given in the appendix, we have

\[
\varphi^2_\alpha(\psi^*(f)) = \varphi^2_\alpha(f) - \left(\frac{1}{12\pi^2} + \alpha\right) \int_M (R_g - (\Omega \circ \psi)^2 R_{\psi g}) f d\mu_g,
\]

where \( \varphi^2_\alpha \) is the field on \((M, g)\) while \( \varphi^2_{\alpha'} \) is the one on \((M, g')\) The particular choice \( \alpha = -1/(12\pi)^2 \) makes the field conformally covariant. We would like to see if this is the case also for more involved fields. Namely we shall look for a particular redefinition of the Wick monomials, by a suitable choice of the renormalization constants \( C_i(x) \) in (8), to get rid of the non homogeneous behavior which is in general present in such cases. We are going to show that this is the case by the following Theorem.

**Theorem 3.1.** Let \( \varphi^k \) be a Wick power as given in (7), there is a non trivial choice of the renormalization constants \( C_i \) in (8) that makes \( \varphi^k \) a conformal locally covariant field with weight \( k \) in the sense of the Definition 1.3.

**Proof.** The proof is constructive: let us consider the following smooth function \( B(x, y) = \frac{1}{2(12\pi)^2} (R_g(x) + R_g(y)) \), then redefine the Wick monomials in the following way,

\[
\varphi^k := : \varphi^k :_{H + B}
\]

13
where
\[ \varphi(x_1) \ldots \varphi(x_k) :_{H+B} = \frac{\delta^k}{i^k f(x_1) \ldots f(x_k)} \exp \left( \frac{1}{2} (H + B) (f \otimes f) + i \varphi(f) \right) \bigg|_{f=0}. \]

The algebra generated using this new normal ordering is isomorphic to \( \mathcal{W}(M, \mathfrak{g}) \), the proof is similar to the one of the independance of the state given in [HW01]; furthermore, it can be shown that : \( \varphi :_{H+B} \) is related to : \( \varphi :_{H} \) by a choice of the renormalization constants as in [S]. The difficult part is to show that the Wick monomials defined with respect to the new normal ordering, satisfy the covariance condition with respect to the conformal embedding \( \psi : (M, \mathfrak{g}) \to (M', \mathfrak{g}') \) in \( \text{CLoc} \) and its corresponding algebraic morphism \( \alpha_{\psi} \) defined as in [5]

\[ \alpha_{\psi}(\varphi^k :_{H+B} (f)) - \varphi^{k'} :_{H'+B'} (\psi^{(4-k)}(f)) = 0. \]

To this end, consider a general element \( W \) of the Wick expansion of \( \varphi^k :_{H+B} (f) \)

\[ W(x_1, \ldots, x_k) := \int \varphi(x_1) \ldots \varphi(x_n) (H + B)(x_{n+1}, x_{n+2}) \ldots (H + B)(x_{k-1}, x_k) \]

\[ t_f(x_1, \ldots, x_k) d\mu^1_\mathfrak{g} \ldots d\mu^k_\mathfrak{g} \] \hspace{1cm} (10)

where \( t_f(x_1, \ldots, x_k) = f(x_1) \Delta(x_1, \ldots, x_k) \). We would like to show that on \( \psi(M)^k \)

\[ S(f') := \alpha_{\psi}(W(t_f)) - W'(t'_{f'}) = 0 \]

where \( W \) is as in [10] and \( W'(x_1, \ldots, x_k) \) is the corresponding term of the expansion of : \( \varphi^{k'} :_{H'+B'} (f') \) on \( (\psi(M), \mathfrak{g}) \) with \( f' := \psi^{(4-k)}(f) \). First of all notice that \( \alpha_{\psi} \) has no action on \( (H + B) \) while

\[ \alpha_{\psi}(\varphi(x)) = \Omega^{-1}(\psi(x)) \varphi'(\psi(x)). \]

Hence

\[ S(f') := \int \varphi'(x_1) \ldots \varphi'(x_n) \]

\[ [\Omega^{-1}(x_{n+1}) \ldots \Omega^{-1}(x_k)(H + B)(x_{n+1}, x_{n+2}) \ldots (H + B)(x_{k-1}, x_k) - (H' + B')(x_{n+1}, x_{n+2}) \ldots (H' + B')(x_{k-1}, x_k)] \]

\[ f' \Delta(x_1, \ldots, x_k) d\mu^1_\mathfrak{g} \ldots d\mu^k_\mathfrak{g}, \]

where we have used the fact that \( f(x_1) \Delta(x_1, x_2) = f(x_2) \Delta(x_1, x_2) \). The proof can be concluded using the analysis presented in the appendix [11], hence for \( y \) in a geodesically convex neighborhood \( O \) of the point \( x \) in \( \psi(M) \), we have that

\[ \lim_{y \to x} \frac{1}{\Omega(x)} (H + B)(\psi^{-1}(x), \psi^{-1}(y)) \frac{1}{\Omega(y)} - (H' + B')(x, y) = 0. \]

From this observation, the proof can be concluded. \( \Box \)
4 Final comments

We have generalized the notion of generally covariant fields to encompass the conformally covariant transformations. This was done exploiting the theory of category in a similar way as in [BFV03]. We have furthermore analyzed the case of the conformally coupled massless Klein Gordon field, studying its Wick powers. Particularly we have shown that, using in a suitable way the renormalization freedom, it is possible to get rid of the non homogeneous part carried by the conformal transformation of those fields. In a certain sense the larger group of covariance reduces the renormalization freedom. The situation presented here is different than the one given in [BFV03], due to the presence of the weights in front of the fields. It is indeed not possible to linearly combine fields with different weights without breaking the conformal covariance, unless position dependent coupling constants are taken into account.

Before concluding the discussion we would like to give some simple examples of other type of fields that fit into the presented framework. As an example of conformally covariant field with non constant couplings consider

$$\lambda_1 : \varphi^4 : H + B + \frac{\lambda_2}{\sqrt{g}} \varphi^2 : H + B + \frac{\lambda_3}{\sqrt{g}}$$

where $g$ is the determinant of the metric and $\lambda_1, \lambda_2, \lambda_3$ are constants. Such a field is a conformally covariant field in the sense of definition 1.3 and its weight is 4.

Other interesting cases arises taking into account fields containing covariant derivatives. Usually that kind of fields are more complicated and it is difficult to draw some general conclusions because of the presence of quantum anomalies, but also because of the non homogeneous transformation rule enjoyed by the covariant derivatives. Nevertheless, also in that case it is possible to construct fields that are conformally covariant, provided a renormalization constant is chosen. As an example of these fields consider

$$- \nabla_a \varphi \Box \varphi : H + \frac{R_g}{12} \nabla_a \varphi^2 : H,$$

notice that their classical counterparts are quite trivial since they vanish. On the other hand, also in that case there is a renormalization freedom of the form $\frac{\lambda_2}{\sqrt{g}}$; we can add to it an homogeneous scaling constant $C$. If $C$ is chosen as $C(x) = -2 \nabla_a v_1(x, x)$ that field turns out to vanish also quantum mechanically and, even if it is a trivial field, it can be interpreted as a conformally covariant field in the sense of definition 1.3.

Acknowledgements.

I would like to thank Romeo Brunetti, Claudio Dappiaggi, Klaus Fredenhagen and Valter Moretti for useful discussions, suggestions and comments on the topic. This work has been supported by the German DFG Research Program SFB 676.

\footnote{For technical details we refer to [Mo03, HW05]}
A Some technical computations

A.1. Transport equations. The coefficient $u$ and $v$ given in the Hadamard parametrix (4) are symmetric smooth functions \[Mo00\] that satisfy the following relations:

$$2\nabla_x\sigma(x,y)\nabla_x u(x,y) + (\Box_x\sigma - 4)u(x,y) = 0, \quad -P_2v = 0.$$ 

Moreover the coefficient $u$ is twice the square root of the van Vleck Morette determinant $u = 2\Delta_1^{1/2}$, for definition and details see \[DB60, Fr75, Fu89, Ta89\]. Furthermore, on a geodesically complete neighborhood, the function $v$ can be expanded as follows

$$v = \sum_{n=0}^p v_n\sigma^n + O(\sigma^n).$$

We have truncated the series at some order $p$ because, in general, the whole series does not converge, unless the coefficients of the metric are analytic functions. Furthermore, the coefficients $v_n$ can be found, using the following two recursive relations valid for $n > 0$

$$2g(x)\nabla_x\sigma\nabla_x v_0 + (\Box_x\sigma(x,y) - 2)v_0 = P_g^{(x)}u(x,y)$$

$$2n\ g(x)\nabla_x\sigma\nabla_x v_n + n\ (\Box_x\sigma(x,y) + 2n - 2)v_n = P_g^{(x)}v_{n-1}(x,y)$$

A.2. Transformation laws for the Hadamard coefficients. Consider a conformal transformation $\psi : (M, g) \to (M, g')$ with conformal factor $\Omega$. Let $H$ and $H'$ be the Hadamard singularity, as given in (4), on a $(M, g)$ and $(M, g')$ respectively. For $y$ in a geodesically complete neighborhood of the point $x$, we would like to compute the coinciding point limit of the subtraction

$$\frac{1}{\Omega(x)}H(x,y) - H'(x,y).$$

Because of the Lemma 2.3 we know that the subtraction is a smooth function, hence we can then compute the following limit directly

$$\lim_{y \to x} \frac{u(x,y)}{\Omega(x)\sigma(x,y)\Omega(y)} + \frac{v(x,y)}{\Omega(x)\Omega(y)} \log \sigma - \frac{u'}{\sigma'} - v' \log \sigma' = R_g^{(x)} - \frac{R_{g'}^{(x)}}{18}. \quad (11)$$

In the computation of the limit (11) we have used the following expansions around $x$. Let $\sigma^\mu = \nabla^\mu_x\sigma$, and $L_\mu := \nabla_\mu\log \Omega$ then we can write the Taylor expansion

$$\Omega(y) = \Omega(x) \left(1 - L_\mu\sigma^\nu + \frac{1}{2} (L_\mu\nu + L_\mu L_\nu) \sigma^\mu\sigma^\nu \right) + O(\sigma^{3/2}).$$

Furthermore using the notation of Fulling’s book \[Fu89\]

$$\sigma'(x,y) = \Omega^2(x)\sigma(x,y) \left(1 - L_\mu\sigma^\nu - \frac{1}{12} (-2\sigma L_\mu L_i + 8L_\mu L_\nu + 4L_\mu L_\nu) \sigma^\mu \sigma^\nu \right) + O(\sigma^{5/2})$$
and the short distance analysis of van Vleck Morette determinant \[DB60\] gives
\[
\Delta^{1/2} = 1 - \frac{1}{12} R_{\mu\nu} \sigma^\mu \sigma^\nu + O(\sigma^2). \tag{12}
\]
Notice that, in the case under investigation, because of the expansion \[12\], and the recursive relations given before, \(v_0(x,x) = v(x,x) = 0\). Plugging the expansions written above into the previous subtraction and knowing that \(v(x,x) = 0\), \(11\) holds.
