Abstract

Aim: This study aimed to evaluate the optimal combination of parameters for the management of pain during surgical abortion using transcutaneous acupoint electrical stimulation (TEAS).

Methods: This study recruited patients scheduled for surgical abortion between October 2014 and August 2015. The treatment protocol was created using three levels for each factor (stimulating time, acupoints, age, and parity). The primary outcomes were intraoperative visual analog scale (VAS), postoperative VAS, cervical relaxation degree and intraoperative blood loss. The secondary outcomes were the vital signs.

Results: Stimulation time was associated with intraoperative VAS scores \((P < 0.001)\), acupoints were associated with postoperative VAS scores \((P = 0.037)\), and age was associated with postoperative VAS scores \((P < 0.043)\). Parity \((P = 0.025)\) was associated with heart rate. A comprehensive analysis of the parameters revealed the best levels for each (stimulation time: from 15 min before operation to immediate postoperative; acupoints: SP 6 and LR 3; patient age 25.1–30.0 years; and parity: \(G_2 \geq P_1 \geq A_1\)). Seven patients did not complete follow-up. The remaining 135 subjects did not show continuous vaginal bleeding, abdominal pain, fever or any other adverse effect.

Conclusion: During surgical abortion, TEAS stimulation from 15 min before operation to immediate postoperative, SP 6 and LR 3, age 25.1–30.0 years and \(G_2 \geq P_1 \geq A_1\) were associated with the best analgesic effect.

Key words: orthogonal design, pain, surgical abortion, transcutaneous electrical acupoint stimulation.

Introduction

Unintended pregnancy accounts for more than 40% of all pregnancies worldwide and induced abortion is one of the ways to manage unintended pregnancies.1 Induced abortion includes medical and surgical abortions. Mifepristone combined with misoprostol is widely used for medical abortion.2 Although medical abortion is associated with less anxiety and pain than surgical abortion,3 there are potential risks of incomplete abortion, excessive bleeding and still ongoing pregnancy.4 On the other hand, surgical abortion is associated with high rates of complete abortion and short postoperative vaginal bleeding. Therefore, it is

widely used in China. Nevertheless, expanding the cervix and scraping the endometrium can induce pain and discomfort and even cause increases of heart rate, changes of blood pressure and abortion syndrome.

Recently, acupuncture anesthesia and transcutaneous acupoint electrical stimulation (TEAS) has been suggested as an alternative to drug therapy for the management of pain. Indeed, TEAS is a new type of acupuncture with analgesic effect. TEAS integrates transcutaneous electrical nerve stimulation therapy and traditional acupuncture therapy. A study showed that TEAS can reduce postoperative pain, nausea and vomiting. TEAS is widely used for analgesia, especially for gynecological surgery and labor. A previous study by our group showed that TEAS may play a supporting role during surgical abortion, but there is no available study about the TEAS parameters associated with the most appropriate management of pain during surgical abortion.

Therefore, this study used an orthogonal design to evaluate the best combination of TEAS parameters for the management of pain during surgical abortion. The tested parameters were stimulation time, acupoint compatibility, age and condition of the patients.

Hence, each of these four parameters was studied at three levels in order to determine the best combination of parameters for the management of pain during surgical abortion.

Methods
Study design
This was a cohort orthogonal design study of patients scheduled for surgical abortion between October 2014 and August 2015 at the outpatient operating room of the Obstetrics and Gynecology department of the First Affiliated Hospital of WenZhou Medical University. The study was approved by the ethics committee of the First Affiliated Hospital of WenZhou Medical University. All study procedures involving human participants were in accordance with the ethical standards of the institutional research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Each patient signed a written informed consent form. This study was registered (Chinese Clinical Trial Registry #ChiCTR-IPR-15007145).

Figure 1 Patient flowchart.

© 2018 The Authors. Journal of Obstetrics and Gynaecology Research published by John Wiley & Sons Australia, Ltd on behalf of Japan Society of Obstetrics and Gynecology
The indications for surgical abortion were:

(i) unwilling to continue pregnancy, the woman was suffering from a disease preventing the continuation of the pregnancy or the fetus had congenital malformations or genetic disease; (ii) pregnancy of less than 10 weeks; and (iii) no contraindication to surgery.\(^3\)

The inclusion criteria were: (i) 18–40 years of age; (ii) gestational age (GA) of 42–70 days; and (iii) confirmed pregnancy by ultrasonography and urinary human chorionic gonadotropin (hCG). The exclusion criteria were: (i) known cardiovascular dysfunction; (ii) renal impairment; (iii) allergy to acupuncture needles or any contraindication to TEAS; (iv) opioid medications within a month; (v) operation puncture needles or any contraindication to TEAS; or (vi) inflammatory disease or psychiatric illness.

Out of the 184 patients evaluated for eligibility, 42 were excluded because they did not meet the eligibility criteria, and 11 declined participation (Figure 1); 142 patients were included, and 135 completed the trial.

**Patients**

An L9 (3\(^4\)) orthogonal design was used in this study (Table 1).\(^{14,15}\) Therefore, the patients were assigned to one of nine TEAS protocols. The subjects, an independent outcome assessor and the statistician were blinded to the implementation of TEAS. As previous studies\(^7-9\) have shown that TEAS has a significant analgesic effect, the present study did not include a control group.

In Table 1, A, B, C and D denote the different treatment parameters, and 1, 2 and 3 indicate the three different levels for each parameter. The details of parameters and levels are shown in Table 2.

| Test number | Column number |
|-------------|---------------|
| T1          | 1 1 1 1      |
| T2          | 1 2 2 2      |
| T3          | 1 3 3 3      |
| T4          | 2 1 2 3      |
| T5          | 2 2 3 1      |
| T6          | 2 3 1 2      |
| T7          | 3 1 3 2      |
| T8          | 3 2 1 3      |
| T9          | 3 3 2 1      |

Fifteen patients were recruited in each group in order to fit the criteria for parameters C and D. Because of the orthogonal design, all groups had to be equal in size. Therefore, if a subject had to be excluded for any reason, new patients were screened until the group was complete.

**Transcutaneous electroacupuncture**

A portable battery-operated electroacupuncture device (HANS-100A, 100100410547, Ji Sheng Company, Beijing, China), which provides electrical current with an intensity of 0–30 mA, was used in this study. A frequency of 100 Hz, burst frequency of 2 Hz (dense-dispersed waveform) and pulse duration of 0.5 ms were used.

The acupuncture points Sanyinjiao (SP 6), Zusanli (ST 36), Taichong (LR 3) and Diji (SP 8) were identified by the investigators, who were Chinese-trained and licensed acupuncturists with a median of 10 years of experience. SP 6 is located on the medial side of the shank, 3 “cun” directly above the tip of the medial malleolus, on the posterior border of the medial aspect of the tibia. ST 36 is located on the anterior aspect of the leg, at 3 “cun” below the knee cap and one finger breadth from the anterior crest of the tibia. LR 3 is located on the dorsum of the foot, in the depression distal to the junction of the first and second metatarsal bones. SP 8 is located on the medial side of the shank, on the line joining the tip of the medial malleolus and Yinlingquan (SP 9) and 3 “cun” below SP 9 (Figures S1–S3, Supporting information). For clarification, the “cun” is a measurement unit for the positioning of acupuncture points. Its full name in English could be “proportional measurement”. It is a standard method that uses the sclerotome as the main marker for positioning. By measuring their size, the length of all body parts can be converted to “cun” according to the proportions. For example, the distance from the wrist to the cubital fossa is traditionally defined as 12 “cun,” meaning that the distance from the wrist to the cubital fossa is divided into 12 equal segments.

All of the selected acupuncture points were swabbed with alcohol following a standard antiseptic process before the TEAS electrodes were applied. Four gel pads were cut to 20 × 20 mm and placed over the acupuncture points (bilaterally). Based on the parameters of Table 2, the anode was attached to SP 6 and the cathode attached to ST 36, LR 3 or SP 8. Each cleaned electrode was placed over the small gel pad; this allowed electrical stimulation to be
focused mainly over the acupuncture points. The electrodes were then attached to the device. The strength of stimulation was increased until the woman felt a comfortable tingling in the area supplied by the nerve being stimulated. This stimulation protocol has been shown to be effective in inducing endorphin production.16

Before surgery, all subjects underwent a gynecological examination, ultrasound, blood routine and serology for HIV, HCV and HBsAg. All patients were monitored using a multifunctional monitor (BeneView T5, Mindray medical international Co., Ltd, Shenzhen, China) for blood pressure (BP), mean arterial pressure (MAP), heart rate (HR) and arterial oxygen saturation (SPO2) during surgery.

The abortion procedure was carried out according to standard clinical practice with a vacuum curette and suction. In the bladder lithotomy position, the vulva, vagina and cervix were disinfected conventionally. The cervix was expanded when the prescribed intervention time with TEAS was reached, as designed in Table 2. According to the size of the gestational sac, a suction tube of suitable size was introduced into the uterine cavity. A thorough vacuum suction was proceed with each stroke in either a clockwise or a counterclockwise manner to ensure that the entire uterine cavity has been covered. Intraoperative blood loss (BL) was measured. All abortions were performed by the same doctor, who is an associate chief physician of obstetrics and gynecology with more than 20 years of experience. After surgery, the participants were transferred to a ward when considered stable with regard to respiration and circulation, according to standard clinical criteria.

**Evaluation indexes**

After enrolment in the study, the participants were interviewed; the study purpose and the use of the visual analog scale (VAS) were explained. All data were recorded by an independent outcome assessor.

In order to assess the effect of TEAS on surgical abortion, the primary outcomes were intraoperative VAS, postoperative VAS, cervical relaxation degree (CRD) and intraoperative BL.

Pain intensity was evaluated with a VAS, which is a 10-cm non-graduated line, with “no discomfort at all” indicated to the “0” end and “discomfort cannot be tolerated” indicated to the “10” end. All patients were asked to evaluate their pain using the VAS during suction in the operating room (worst pain during the procedure) and at 30 min after surgery in the ward. The patient was handed a clipboard with the VAS and was supervised by an independent outcome assessor. Two different forms were used for the two assessments.

Intraoperative BL was measured after filtration of the tissues using a measuring cup.17 The operative time was recorded as the time from the start of cervical dilatation until the end of suction. CRD was directly recorded as the number of cervical dilators that were entered into the intracervical mouth smoothly.18 The secondary outcomes were the range of BP (systolic/diastolic), MAP, SPO2 and HR, recorded at the beginning of the operation ($T_0$), at the time of suction ($T_1$) and 30 min after the operation ($T_2$).

**Follow-up**

All participants were followed up by telephone. Follow-up included whether there was continuous vaginal bleeding, abdominal pain or fever.

**Sample size estimation**

Sample size estimation was based on the comparison of two groups from an independent sample. The estimation was based on the assumption that TEAS could decrease the mean VAS by at least 2 points, assuming a standard deviation of 1.5. To yield a power of 90% with $\alpha = 0.05$, a sample size of at least 12 subjects in each group was required. The analysis was performed using SPSS 18.0 for Windows (IBM, Armonk, NY, USA).

Pain during surgical abortion may be managed using TEAS stimulation from 15 min before operation to immediate postoperative, SP 6 and LR 3, age 25.1–30.0 years and Gc2P0A<0.1 showed the best analgesic effects.

Adverse effects

Seven patients did not complete the follow-up. The remaining 135 subjects did not show continuous vaginal bleeding, abdominal pain, fever or any other adverse effect.

Discussion

Pain during surgical abortion may be managed using a number of drug protocols. TEAS can be used to manage pain in surgical patients, for gynecological surgery and labor and for surgical abortion, but the optimal parameters for pain management during surgical abortion are unknown. Therefore, this study used an orthogonal design to compare the effectiveness of three different levels of four intervention parameters of TEAS for the management of pain during surgical abortion. In order to eliminate the influence of other factors, drugs, including narcotics, were not allowed. No control group is allowed in the orthogonal design. The results showed that during surgical abortion, TEAS stimulation from 15 min before operation to immediate postoperative, SP 6 and LR 3, age 25.1–30.0 years and Gc2P0A<0.1 were associated with the best analgesic effects.

To the best of the authors’ knowledge, this is the first report on the use of TEAS alone during surgical abortion using an orthogonal design. Because of the
