ABSTRACT

Objectives To explore whether children born extremely preterm (EPT) with different types of sleep problems had more behavioural and respiratory health problems than EPT children without sleep problems.

Design Prospective, nationwide, questionnaire-based study. At 11 years of age, parents reported on four current sleep problems: difficulty falling asleep or frequent awakenings, snoring, daytime sleepiness and not recommended sleep duration (<9 hours). Behavioural problems were assessed by parents and teachers with the Strengths and Difficulties Questionnaire (SDQ). Parents assessed respiratory symptoms with the International Study of Asthma and Allergies in Childhood questionnaire and described use of asthma medication.

Setting Norway.

Patients EPT children.

Main outcome measures Specified sleep problems, behavioural problems and respiratory health.

Results Data were obtained from 216 of 372 (58%) of eligible children. All four specified sleep problems were associated with significantly higher parent-reported SDQ total-score (OR 1.1 for all), and except for not recommended sleep duration, also with higher teacher-reported SDQ total-score (OR 1.1 for all). Daytime sleepiness was strongly associated with wheezing last 12 months (OR 3.4), disturbed sleep due to wheezing (OR 3.9), wheeze during or after exercise (OR 2.9), use of inhaled corticosteroids or oral leukotriene modifiers (OR 3.4) and use of bronchodilators (OR 3.9). Snoring was associated with wheezing during or after exercise (OR 2.8) and current asthma (OR 4.2).

Conclusion EPT children with different types of sleep problems had more behavioural and respiratory health problems than EPT children without sleep problems.

INTRODUCTION

Sleep is critical for development, maturation and health on the journey from infancy to adulthood.1 Sleep problems in children have been associated with asthma and other respiratory symptoms,2 and with mental health problems, such as conduct problems, hyperactivity and emotional problems.3-5 Children with neurological disabilities often have sleep problems,6 but somatic and mental comorbidities may contribute to these problems.7-9

We have previously shown that children born extremely preterm (EPT) have more sleep problems throughout childhood than children born at term, and that the prevalence increases with the degree of neurodevelopmental disability.10 Children born EPT are also at increased risk of behavioural problems and respiratory morbidities,11 12 but we do not know how such difficulties affect their sleep.

We hypothesised that sleep problems at 11 years in children born EPT are associated with behavioural problems and respiratory symptoms and aimed to explore the significance of these relationships by addressing four specified sleep problems: difficulty falling asleep or frequent awakenings, snoring, daytime sleepiness and insufficient sleep duration.
METHODS
Population
The study population was a national cohort of all children born EPT (n=372) in Norway during 1999–2000. EPT was defined as gestational age (GA) <28 completed weeks or birth weight (BW) <1000 g. The children were prospectively followed from birth and assessed at 2, 5 and 11 years of age. Method for determination of GA and overall outcome in terms of mortality and morbidities until 11 years have been published previously. At 11 years, we obtained information on the families' sociodemographic characteristics and lifestyles, and the children's health, including sleep characteristics, behavioural issues and respiratory health, from postal questionnaires completed by the parents (for behaviour also the children's teacher). EPT children with severe disability were included. (The degree of neurodevelopmental disability was assessed by clinical examination when the children were 5 years old.)

Sleep problems
The parents assessed the sleep problems in terms of whether their child had difficulty falling asleep or had frequent awakenings, snored or had daytime sleepiness. The response options to these questions were 'Not true', 'Partly true' and 'Absolutely true'. In our analyses, the responses 'Partly true' and 'Absolutely true' were merged and defined as a sleep problem. Sleep duration was assessed by the following items: at what time their child went to bed and got up on weekdays, how long time it took from going to bed until falling asleep (sleep onset latency) and how long the child was awake during the night after sleep onset. We calculated total sleep duration as the time in bed minus sleep onset latency and time awake after sleep onset. In accordance with recently published guidelines, recommended sleep duration at 11 years was defined as 9–11 hours. The same sleep variables have been used in a previous paper.

Behavioural problems
Parents and teachers completed the Strengths and Difficulties Questionnaire (SDQ). SDQ is a general behavioural screening questionnaire for 4–17-year-old children and has good psychometric properties also for children born preterm. It contains five items in each of four subscales: emotional problems, hyperactivity/inattention, conduct problems and peer problems. Each item is scored on a three-point scale; 'Not true' (0), 'Somewhat true' (1) and 'Certainly true'. The total subscale score ranges from 0 to 10 and the total score from 0 to 40.

Respiratory health
The parents completed the International Study of Asthma and Allergies in Childhood (ISAAC) questionnaire which contains the following questions on respiratory symptoms during the last 12 months: did your child experience wheezing or whistling in the chest and, if so, how many attacks; how often was the child’s sleep disturbed due to wheezing; was wheezing ever so severe that the child had trouble saying more than one or two words at a time between breaths; did the child’s chest sounded wheezy during or after exercise; and did the child have a dry cough at night, apart from cough associated with a cold or chest infection.

We also asked for current use of asthma medications, including inhaled corticosteroids, short or long acting β₂-agonists and oral leukotriene modifiers, and whether the child had ever been diagnosed with asthma. Current asthma was defined as yes to ‘ever asthma’ combined with either respiratory symptoms or use of asthma medication during the previous 12 months, or asthma medication and symptoms during the past 12 months regardless of reporting asthma.

Statistical analyses
For each specific dichotomised sleep outcome variable, the groups were compared according to the results on the SDQ, ISAAC, current asthma versus no asthma, use versus no use of inhaled corticosteroids or oral leukotriene modifiers, and use versus no use of inhaled bronchodilators.

Group comparisons were performed using Student’s t-tests, χ² tests or Fisher’s exact tests. ORs and 95% CIs were calculated after adjusting for sex, single parenthood and maternal education (dichotomised as a 3-year college education or not) in logistic regression analyses. Significance level was set at α-level 0.05. We also performed subanalyses where we included small for gestational age (SGA) as a covariate. This was done for the SDQ and for the questions about respiratory health. SGA was defined as a BW below the 10th percentile. For the questions about respiratory health, subanalyses were also made in which information about current smoking among parents (mother or father) was included as a covariate.

Patient and public involvement
Patient representatives were involved in this national follow-up study.

RESULTS
Sleep and ISAAC data were obtained for 216/372 (58%) children. SDQ was completed by the parents for 215 and by the teachers for 184 of them. Difficulty falling asleep or frequent awakenings was reported for 27.3%, snoring for 28.0%, daytime sleepiness for 17.1% and sleep duration less than the recommended 9 hours for 24.1% of the children. None of the children slept more than recommended. There were no significant sex differences regarding the prevalence of the specified sleep problems. The average total SDQ score was 8.8 and the prevalence of current asthma was 18%. Of the 216 participating children, six had severe disability at age 5 years. Parent and child characteristics are described in table 1. Participants and non-participants did not differ regarding GA or the ratio of SGA, bronchopulmonary dysplasia or...
Sleep problems and respiratory health

The children who had difficulty falling asleep or frequent awakenings more often had wheezing during the last 12 months, but the association did not remain significant after adjustment (table 3). Only two children had problems with speaking due to wheezing. This question was therefore not included in the further analyses.

Snoring was associated with wheezing during or after exercise, current asthma and use of bronchodilators (table 3). Daytime sleepiness was associated with wheezing during the last 12 months, disturbed sleep due to wheezing, wheeze during or after exercise, use of inhaled corticosteroids or oral leukotriene modifiers and use of bronchodilators (table 3). Sleep duration less than recommended was associated with disturbed sleep due to wheezing and use of inhaled corticosteroids or oral leukotriene modifiers (table 3). The association between these specific sleep problems and the respiratory health problems remained unchanged after including SGA and the parents’ current smoking habits (mother or father smoking) as covariates in the adjusted analysis (data not shown).

DISCUSSION

In this nationwide cohort of EPT children, sleep problems were significantly associated with behavioural and respiratory health problems. Difficulty falling asleep or frequent awakenings, snoring and daytime sleepiness were associated with more parent-reported and teacher-reported behavioural problems, whereas sleeping less than recommended was associated with more parent-reported behavioural problems. The sleep problems, and especially daytime sleepiness, were strongly associated with respiratory symptoms, asthma and use of asthma medication.

The average total SDQ scores in our study were higher (total score 8.8) than previously found in unselected Norwegian children (total score 5.4). The prevalence of current asthma (18%) was higher than the prevalence of 11% in an unselected Norwegian cohort of 10-year-old children. Thus, this EPT cohort had more respiratory problems, and especially daytime sleepiness, were strongly associated with respiratory symptoms, asthma and use of asthma medication.

The average total SDQ scores in our study were higher (total score 8.8) than previously found in unselected Norwegian children (total score 5.4). The prevalence of current asthma (18%) was higher than the prevalence of 11% in an unselected Norwegian cohort of 10-year-old children. Thus, this EPT cohort had more respiratory problems, and especially daytime sleepiness, were strongly associated with respiratory symptoms, asthma and use of asthma medication.

The average total SDQ scores in our study were higher (total score 8.8) than previously found in unselected Norwegian children (total score 5.4). The prevalence of current asthma (18%) was higher than the prevalence of 11% in an unselected Norwegian cohort of 10-year-old children. Thus, this EPT cohort had more respiratory problems, and especially daytime sleepiness, were strongly associated with respiratory symptoms, asthma and use of asthma medication.

Table 1 Characteristics of the 216 of 372 eligible children who were born extremely preterm* in Norway in 1999–2000 and participated in the follow-up at 11 years of age

| Family background | % (n) |
|-------------------|-------|
| Single parent     | 8.8 (19) |
| Higher education mother† | 68.8 (148) |
| Higher education father† | 45.1 (96) |

| Demographic characteristics | Mean (range) |
|-------------------------------|-------------|
| Gestational age, weeks        | 26.6 (23.0–32.0) |
| Birth weight, grams           | 869 (450–1370) |
| Small for gestational age‡     | 18.1 (39) |
| Boy                            | 51.4 (111) |
| Severe disability§ (based on clinical examination at 5 years) | 3.3 (6) |
| Current smoking, mother or father | 35.2 (76) |

*Gestational age <28 weeks or birth weight <1000 g.
†College or university education when the child was 11 years old.

during the night, and that these difficulties were related to problems with emotions and attention, which is in agreement with our findings. It is worth noting that Perkinson-Gloor et al excluded children with severe developmental delay and that Caravale Perkinson-Gloor in agreement with our findings. It is worth noting that Norwegian children of similar age.36

activity/inattention problems in an unselected cohort of and emotional problems, conduct problems and hyper-

findings of an association between short sleep duration associated with higher SDQ total-scores is in agreement with our observations in EPT-born. Snoring in term-born children has also been associated with emotional problems, conduct problems and hyperactivity/inattention problems in term born children measured by SDQ of Hestetun et al. These are findings that are in line with our observations in EPT-born children, strengthening the notion that sleep problems are likely to be similarly involved in mental health issues in preterm as well as term-born children.

Snoring in term-born children has also been associated with emotional problems, conduct problems and hyperactivity/inattention problems as assessed by SDQ. Correspondingly, we found more emotional and conduct problems, but not more hyperactivity/inattention problems among our snoring EPT children. Snoring is a common symptom of sleep disordered breathing (SDB), and previous studies have shown that children born prematurely have an increased risk of SDB. The prevalence SDB during childhood in children born EPT is unknown. In general, SDB in childhood is a risk factor for behavioural problems, externalising symptoms and inattention. More studies are needed to map the association between SDB and behavioural problems in children born EPT.

Our finding that insufficient sleep duration was associated with higher SDQ total-scores is in agreement with findings of an association between short sleep duration and emotional problems, conduct problems and hyperactivity/inattention problems in an unselected cohort of Norwegian children of similar age.36

We are unaware of other studies that have addressed relationships between respiratory symptoms and sleep in children born EPT, but our finding that several sleep problems were associated with wheezing and asthma is in agreement with similar findings in children born at term. Although respiratory symptoms in EPT-born children resemble asthma, the pathophysiology of lung disease after preterm birth is different which, for instance, is reflected in that the disease is unresponsive to inhaled corticosteroids. Their burden of respiratory symptoms may therefore be substantially higher, and more chronic and therefore more easily overlooked. For example, it is conceivable that poor sleep due to respiratory problems may cause daytime sleepiness and contribute to inattention and learning difficulties which are major challenges for children born EPT.43 44 Previous studies on term-born children have shown that nocturnal awakening due to asthma is a risk factor for poor school functioning.45

The strengths of the present study were the national population-based sample of EPT children, the prospective design, the assessment of behavioural problems by both parents and teachers, and the use of validated instruments for assessing both behavioural problems and respiratory symptoms. The limited response rate at follow-up was a weakness. However, we found that for most variables the assessed children were representative of all survivors at the age of 11 years. We adjusted for single parenthood, maternal education and sex in our analyses, and in subanalyses we also adjusted for SGA and current smoking among parents. We cannot, however, exclude residual confounding. We did not correct for multiple testing, and therefore, the results must be interpreted with caution. Other limitations were lack of detailed information about socioeconomic status, the child’s sleep environment, what season the parents answered the questionnaires, and whether the children had been treated for snoring or for sleep problems.

CONCLUSIONS
In the present study, behavioural problems and respiratory symptoms were strongly associated with sleep disturbances in 11-year-old children born EPT. The associations were similar to what has been found in unselected groups of children. Given the high prevalence of behavioural problems and respiratory symptoms after preterm birth, the study suggests that sleep disturbances may be an overlooked area of concern in preterm born children, and that questions mapping sleep should be included when seeing these children in clinics.
