Abstract
Most fairness assumptions used for verifying liveness properties are criticised for being too strong or unrealistic. On the other hand, justness, arguably the minimal fairness assumption required for the verification of liveness properties, is not preserved by classical semantic equivalences, such as strong bisimilarity. To overcome this deficiency, we introduce a finer alternative to strong bisimilarity, called enabling preserving bisimilarity. We prove that this equivalence is justness-preserving and a congruence for all standard operators, including parallel composition.

1 Introduction

Formal verification of concurrent systems becomes more and more standard practice, in particular in safety-critical environments. Progress and fairness assumptions have to be used when verifying liveness properties, which guarantee that ‘something good will eventually happen’. Without assumptions of this kind, no meaningful liveness property can formally be proven.

Example 1. Consider the program
\[ \text{while}(\text{true}) \text{ do } \text{x}:=\text{x}+1 \text{ od} \]
with \( \text{x} \) initialised to 0. Intuitively, any liveness property of the form ‘eventually \( \text{x}=\text{n} \)’ should be satisfied by the program. However, these properties are valid only when assuming progress, stating that a system will make progress when it can; otherwise the program could just stop after some computation.

Progress itself is not a strong enough assumption when concurrent systems are verified, for a system of multiple completely independent components makes progress as long as one of its components makes progress, even when others do not. For decades, researchers have developed notions of fairness and used them in both system specification and verification; the most common ones are surveyed in [13]. Two of the most popular fairness assumptions are weak and strong fairness of instructions [5]. They apply to systems whose behaviour is specified by some kind of code, composed out of instructions. A task is any activity of the system that stems from a particular instruction; it is enabled when the system is ready to do some part of that task, and executed when the system performs some part of it. Now weak and strong fairness of instructions state that whenever a task is enabled persistently (for

\[ 1 \] often these notions are referred to as weak and strong fairness without mentioning instructions; here, we follow the terminology of [13], which is more precise.
weak fairness) or infinitely often (for strong fairness), then it will be executed by the system. These fairness assumptions, as well as all others surveyed in [13], imply progress.

Despite being commonly used, it has been argued that most fairness assumptions, including weak and strong fairness of instructions, are often too strong or unrealistic, “in the sense that run-of-the-mill implementations tend not to be fair” [13].

(Reactive) systems are often described by labelled transition systems, which model all activities as transitions going from state to state, labelled with actions. Some actions require synchronisation of the modelled system with its environment; they can occur only when both the system and the environment are ready to engage in this action. Such actions, and the transitions labelled with them, are called blocking.

Example 2. Assume that every morning Alice has a choice between a slice of bread with jam or a bacon and egg roll. A corresponding transition system consists of one state with two transitions, each standing for one kind of breakfast. Both weak and strong fairness (of instructions) will force Alice to eventually have both types of breakfast, ruling out the possibility that Alice picks up jam every day as she is a vegetarian.

To address this issue, a weaker assumption, called justness, has been proposed. It has been formulated for reactive systems, modelled as labelled transition systems. Justness is the assumption that

Once a non-blocking transition is enabled that stems from a set of parallel components, one (or more) of these components will eventually partake in a transition. [13]

Example 2 features only one component, Alice. Assuming justness, as expected, she now has the option to eat jam for the rest of her life. Let us now look at a more technical example.

Example 3. We consider the following two programs, and assume that all variables are initialised by 0.

```plaintext
while(true) do
  choose
  if true then y := y+1; od
  if x = 0 then x := 1; od
od
```

```plaintext
while(true) do
  x := 1;
  y := y+1;
od
```

The example on the left presents an infinite loop containing an internal nondeterministic choice. The conditional write if x = 0 then x := 1 describes an atomic read-modify-write (RMW) operation. Such operators, supported by modern hardware, read a memory location and simultaneously write a new value into it. This example is similar to Example 2 in the sense that the liveness property ‘eventually x=1’ should not be satisfied as the program has a choice every time the loop body is executed.

The example on the right-hand side is similar, but the handling of variables x and y are managed by different components. As the two programs are independent from each other – they could be executed on different machines – the property ‘eventually x=1’ should hold.

Justness differentiates these behaviour, whereas weak and strong fairness fail to do so.

The above example illustrates that standard notions of fairness are regularly too strong,

---

2 Many other notions of fairness are obtained by varying the definition of task. In fairness of components a task refers to all activity stemming from a component of a system that is a parallel composition.

3 https://en.wikipedia.org/wiki/Read-modify-write
and the notion of justness may be a good replacement. When it comes to verification tasks, semantic equivalences, such as strong bisimilarity [17], are a standard tool to reduce the state space of the systems under consideration. Unfortunately, these semantic equivalences do not accord well with justness. The problem is that they are based on labelled transition systems, which do not capture the concept of components. The different behaviour of the two programs in Example 3 stems from the components involved. In fact, both programs give rise to the same transition system, depicted on the right. Systems featuring the same transition system cannot be distinguished by any semantic equivalence found in the literature. Consequently, the verification of the stated liveness property will fail for one of the two programs of Example 3.

To overcome this deficiency, we introduce enabling preserving bisimilarity, a finer alternative to strong bisimilarity, which respects justness. It is based on extended labelled transition systems that take components involved in particular transitions into account.

2 Labelled Transition Systems with Successors

As discussed in the introduction, one reason why strong bisimilarity does not preserve liveness properties under justness is that necessary information is missing, namely components.

The definition of (parallel) components was based on the parallel composition operator in process algebras when justness was first introduced in [4, 12], and has been generalised in later work to allow the use of justness in different contexts.

Here we define a justness-preserving semantic equivalence on an extension of labelled transition systems. Using labelled transition systems rather than process algebra as underlying concept makes our approach more general, for other models of concurrency, such as Petri nets or higher-dimensional automata, induce a semantics based on transition systems as well.

The essence of justness is that when a non-blocking transition \( t \) is enabled in a state \( s \), eventually the system must perform an action \( u \) that interferes with it [13], notation \( t \not\mathcal{R} u \), in the sense that a component affected by \( u \) is necessary for the execution of \( t \) or, to be more precise, for the variant \( t' \) of \( t \) that is enabled after the system has executed some actions that do not interfere with \( t \). The present paper abstracts from the notion of component, but formalises justness, as well as our enabling preserving bisimilarity, in terms of a successor relation \( t \sim_{\mathcal{R}} t' \), marking \( t' \) as a successor of \( t \), parametrised with the noninterfering actions \( \pi \) happening in between. This relation also encodes the above relation \( \not\mathcal{R} \). The advantage of this approach over one that uses components explicitly, is that it also applies to models like higher-dimensional automata [20, 6, 15, 8] in which the notion of a component is more fluid, and changes during execution.

A labelled transition system (LTS) is a tuple \((S, Tr, source, target, \ell)\) with \( S \) and \( Tr \) sets (of states and transitions), source, target : \( Tr \to S \) and \( \ell : Tr \to \mathcal{L} \), for some set \( \mathcal{L} \) of transition labels. A transition \( t \in Tr \) of an LTS is enabled in a state \( p \in S \) if source\((t) = p \). Let \( en(p) \) be the set of transitions that are enabled in \( p \).

A path in an LTS is an alternating sequence \( p_0 u_0 p_1 u_1 p_2 \ldots \) of states and transitions, starting with a state and either being infinite or ending with a state, such that source\((u_i) = p_i \) and target\((u_i) = p_{i+1} \) for all relevant \( i \). The length \( l(\pi) \in \mathbb{N} \cup \{\infty\} \) of a path \( \pi \) is the number of transitions in it. If \( \pi \) is a path, then \( \hat{\pi} \) is the sequence of transitions occurring in \( \pi \).

\textbf{Definition 4 (LTSS).} A labelled transition system with successors (LTSS) is a tuple \((S, Tr, source, target, \ell, \sim)\) with \((S, Tr, source, target, \ell)\) an LTS, and \( \sim \subseteq Tr \times Tr \times Tr \), the successor relation, such that if \((t, u, v) \in \sim\) then source\((t) = source(u) \) and source\((v) = target(u) \). We write \( t \sim_{u} v \) for \((t, u, v) \in \sim\).
We use this successor relation to define the concept of (un)affected transitions. Let two transitions \( t \) and \( u \) be enabled in a state \( p \), i.e., \( t, u \in \text{en}(p) \) for some \( p \in S \); the concurrency relation \( \sim \) is defined as \( t \sim u :\iff \exists v. t \sim u v \). Its negation \( t \not\sim u \) says that the possible occurrence of \( t \) is affected by the occurrence of \( u \). In case \( t \) is unaffected by \( u \) (i.e., \( t \sim u \)), each \( v \) with \( t \sim u v \) denotes a variant of \( t \) that can occur after \( u \). Note that the concurrency relation can be asymmetric. Examples are traffic lights – a car passing traffic lights should be affected by them, but the lights do not care whether the car is there; and read-write operations – reading shared memory can be affected by a write action, but, depending on how the memory is implemented, the opposite might not hold. In case \( t \) and \( u \) are mutually unaffected we write \( t \sim u \), i.e., \( t \sim u :\iff t \sim u \land u \sim t \).

It is possible to have \( t \not\sim t \), namely when executing transition \( t \) does not disable (a future variant of) \( t \) to occur again. This can happen when \( t \) is a signal emission, say of a traffic light shining red, for even after shining for some time it keeps on shining; or when \( t \) is a broadcast receive action, for receiving a broadcast does not invalidate a system’s perpetual readiness to again accept a broadcast, either by receiving or ignoring it.

**Example 5.** Consider the labelled transition system of Example 3, let \( t_1 \) and \( t_2 \) be the two transitions corresponding to \( y:=y+1 \) in the first and second state, respectively, and let \( u \) be the transition for assignment \( x:=1 \). The assignments of \( x \) and \( y \) in the right-hand program are independent, hence \( t_1 \sim u t_2 \), \( u \sim t_1 \), \( u \) and \( t_1 \sim u \).

For the program on the left-hand side, the situation is different. As the instructions stem from the same component (program), all transitions affect each other, i.e., \( \sim = \not\sim = \emptyset \).

The successor relation relates transitions one step apart. We lift it to sequences of transitions.

**Definition 6 (Successor along Path).** The relation \( \sim \) is extended to \( \sim \subseteq \mathcal{Tr} \times \mathcal{Tr}^* \times \mathcal{Tr} \) by

\[
(i) \quad t \sim_{\varepsilon} w \iff w = t,
(ii) \quad t \sim_{\pi u} w \iff \text{there is a } v \text{ with } t \sim_{\pi} v \text{ and } v \sim_{\pi u} w.
\]

Here, \( \varepsilon \) denotes the empty sequence, and \( \pi u \) the sequence \( \pi \) followed by transition \( u \). We define a concurrency relation \( \sim \subseteq \mathcal{Tr} \times \mathcal{Tr}^* \times \mathcal{Tr} \) considering sequences of transitions by \( t \sim_{\pi} \pi :\iff \exists v. t \sim_{\pi} v \). Intuitively, \( t \sim_{\pi} \pi \) means that there exists a successor of \( t \) after \( \pi \) has been executed. Thus, \( t \) is unaffected by all transitions of \( \pi \).

We are ready to define justness, which is parametrised by a set \( B \) of blocking actions.

**Definition 7 (Justness).** Given an LTSS \( \mathcal{LTS} = (S, \mathcal{Tr}, \text{source}, \text{target}, \ell, \sim) \) labelled over \( \mathcal{L} \), and \( B \subseteq \mathcal{L} \), a path \( \pi \) in \( \mathcal{LTS} \) is \( B \)-just if for each suffix \( \pi_0 \) of \( \pi \) and for each transition \( t \in \mathcal{Tr}^* \) with \( \ell(t) \notin B \) and \( \text{source}(t) \) the first state of \( \pi_0 \), the path \( \pi_0 \) has a finite prefix \( \rho \) such that \( t \not\sim \rho \). Here \( \mathcal{Tr}^* := \{ t \in \mathcal{Tr} \mid t \not\sim t \} \).

### 3 Enabling Preserving Bisimulation Equivalence

In this section we introduce enabling preserving bisimulation equivalence, and show how it preserves justness. In contrast to classical bisimulations, which are relations of type \( S \times S \), the new equivalence is based on triples. The essence of justness is that a transition \( t \) enabled in a state \( s \) must eventually be affected by the sequence \( \pi \) of transitions the system performs. As long as \( \pi \) does not interfere with \( t \), we obtain a transition \( t' \) with \( t \sim_{\pi} t' \). This transition \( t' \) represents the interests of \( t \), and must eventually be affected by an extension of \( \pi \). Here, executing \( t \) or \( t' \) as part of this extension is a valid way of interfering. To create a bisimulation that respects such considerations, for each related pair of states \( p \) and \( q \) we also match each enabled transition of \( p \) with one of \( q \), and vice versa. These relations are maintained during the evolution of the two related systems, so that when one system finally interferes with a descendant of \( t \), the related system interferes with the related descendant.
Definition 8 (Ep-bisimilarity). Given an LTSS \((S, \mathcal{T}, \text{source}, \text{target}, \ell, \sim)\), an enabling preserving bisimulation (ep-bisimulation) is a relation \(\mathcal{R} \subseteq S \times S \times \mathcal{P}(\mathcal{T} \times \mathcal{T})\) satisfying

1. if \((p, q, R) \in \mathcal{R}\) then \(R \subseteq \text{en}(p) \times \text{en}(q)\) such that
   a. \(\forall t \in \text{en}(p). \exists u \in \text{en}(q). \ell(t) = \ell(u)\), and
   b. \(\forall u \in \text{en}(q). \exists t \in \text{en}(p). \ell(t) = \ell(u)\), and
   c. if \(t R u\) then \(\ell(t) = \ell(u)\), and
2. if \((p, q, R) \in \mathcal{R}\) and \(v R w\), then \((\text{target}(v), \text{target}(w), R') \in \mathcal{R}\) for some \(R'\) such that
   a. \(t R u\) and \(t \sim_v u'\), then \(\exists v'. u \sim_w u' \land t' R' u'\), and
   b. \(t R u\) and \(u \sim_w v'\), then \(\exists t'. t \sim_v t' \land t' R' u'\).

Two states \(p\) and \(q\) in an LTSS are enabling preserving bisimilar (ep-bisimilar), \(p \equiv_{ep} q\), if there exists an enabling preserving bisimulation \(\mathcal{R}\) such that \((p, q, R) \in \mathcal{R}\) for some \(R\).

Definition 8 without Items 2a and 2b is nothing else than a reformulation of the classical definition of strong bisimilarity. An ep-bisimulation additionally maintains for each pair of related states \(p\) and \(q\) a relation \(R\) between the transitions enabled in \(p\) and \(q\). Items 2a and 2b strengthen the condition on related target states by requiring that the successors of related transitions are again related relative to these target states. It is this requirement (and in particular its implication stated in the following observation) which distinguishes the transition systems for Example 3.

Observation 9. Ep-bisimilarity respects the concurrency relation.

For a given ep-bisimulation \(\mathcal{R}\), if \((p, q, R) \in \mathcal{R}\), \(t R u\) and \(v R w\) then \(t \sim v\) iff \(u \sim w\).

Proposition 10. \(\equiv_{ep}\) is an equivalence relation.

Proof. Reflexivity: Let \((S, \mathcal{T}, \text{source}, \text{target}, \ell, \sim)\) be an LTSS. The relation

\[
\mathcal{R}_{id} := \{(s, s, \text{Id}_s) \mid s \in S\}
\]

is an ep-bisimulation. Here \(\text{Id}_s := \{(t, t) \mid t \in \text{en}(s)\}\).

Symmetry: For a given ep-bisimulation \(\mathcal{R}\), the relation

\[
\mathcal{R}^{-1} := \{(q, p, R^{-1}) \mid (p, q, R) \in \mathcal{R}\}
\]

is also an ep-bisimulation. Here \(R^{-1} := \{(u, t) \mid (t, u) \in R\}\).

Transitivity: For given ep-bisimulations \(\mathcal{R}_1\) and \(\mathcal{R}_2\), the relation

\[
\mathcal{R}_1; \mathcal{R}_2 := \{(p, r, R_1; R_2) \mid \exists q. (p, q, R_1) \in \mathcal{R}_1 \land (q, r, R_2) \in \mathcal{R}_2\}
\]

is also an ep-bisimulation. Here \(R_1; R_2 := \{(t, v) \mid \exists u. (t, u) \in R_1 \land (u, v) \in R_2\}\).

Observation 11. The union of any collection of ep-bisimulations is itself an ep-bisimulation.

Consequently there exists a largest ep-bisimulation.

Before proving that ep-bisimilarity preserves justness, we lift this relation to paths.

Definition 12 (Ep-bisimilarity of Paths). Given an ep-bisimulation \(\mathcal{R}\) and two paths \(\pi = p_0 u_0 p_1 p_2 \ldots\) and \(\pi' = p'_0 u'_0 p'_1 p'_2 \ldots\), we write \(\pi \equiv \pi'\) iff \(l(\pi) = l(\pi')\), and there exists \(R_i \subseteq \mathcal{T} \times \mathcal{T}\) for all \(i \in \mathbb{N}\) with\( i \leq l(\pi)\), such that

1. \((p_i, p'_i, R_i) \in \mathcal{R}\) for each \(i \in \mathbb{N}\) with \(i \leq l(\pi)\),
2. \(u_i R_i u'_i\) for each \(i < l(\pi)\),
3. if \(t R_i t'\) and \(t \sim u_i v\) with \(i < l(\pi)\), then \(\exists v'. t' \sim v'\) \(v' \in R_i + v'\), and
4. if \(t R_i t'\) and \(t' \sim u'_i v'\) with \(i < l(\pi)\), then \(\exists v. t \sim v\) \(v \in R_i + v'\).

Paths \(\pi\) and \(\pi'\) are enabling preserving bisimilar, notation \(\pi \equiv_{ep} \pi'\), if there exists an ep-bisimulation \(\mathcal{R}\) with \(\pi \equiv \pi'\). If \(\pi \equiv_{ep} \pi'\), we also write \(\pi \equiv R \pi'\) if \(\overline{\pi} := (R_0, R_1, \ldots)\) are the \(R_i\) required above.
Note that if $p \trianglelefteq_{ep} q$ and $\pi$ is any path starting from $p$, then, by Definition 8, there is a path $\pi'$ starting from $q$ with $\pi \trianglelefteq_{ep} \pi'$. The following lemma lifts Observation 8.

**Lemma 13.** If $\pi R \rho$ with $\pi$ finite and $t R_0 t'$ then $t \sim_{\pi} \hat{\rho}$.

**Proof.** We have to show that $\exists v.\ t \sim_{\pi} v$ if $\exists \rho'.\ t' \sim_{\rho'} v'$. Using symmetry, we may restrict attention to the “only if” direction. We prove a slightly stronger statement, namely that for every transition $v$ with $t \sim_{\pi} v$ there exists a $v'$ such that $t' \sim_{\rho} v'$ and $v R_0(\pi) v'$.

We proceed by induction on the length of $\pi$.

The base case, where $l(\pi) = 0$, $\pi = \varepsilon$ and thus $v = t$, holds trivially, taking $v' = t'$.

So assume $\pi u R \rho u' \rho'$ and $t \sim_{\pi} w$. Then there is a $v$ with $t \sim_{\pi} v$ and $v \sim_{\varepsilon} w$. By induction there is a transition $v'$ such that $t' \sim_{\rho} v'$ and $v R_0(\pi) v'$. By Definition 12(3), there is a $w'$ with $v' \sim w' w'$ and $w R_0(\pi) w'$. Thus $t' \sim_{\rho u'} w'$ by Definition 6. \hfill $\blacktriangle$

**Theorem 14.** Ep-bisimilarity preserves justness: Given two paths $\pi$ and $\pi'$ in an LTSS with $\pi \trianglelefteq_{ep} \pi'$, and a set $B$ of blocking actions, then $\pi$ is $B$-just iff $\pi'$ is $B$-just.

**Proof.** Let $\pi = p_0 u_0 p_1 u_1 p_2 \ldots$ and $\pi' = p'_0 u'_0 p'_1 u'_1 p'_2 \ldots$. Suppose $\pi$ is $B$-unjust, so there exist an $i \in N$ with $i \leq l(\pi)$ and a transition $t \in Tr^*$ with $\ell(t) \notin B$ and $source(t) = p_i$ such that $t \sim_{\rho} \hat{\rho}$ for each finite prefix $\rho$ of the suffix $p_i u_i p_{i+1} u_{i+1} p_{i+2} \ldots$ of $\pi$. It suffices to show that also $\pi'$ is $B$-unjust.

Take an ep-bisimulation $\mathcal{R}$ such that $\pi \mathcal{R} \pi'$. Choose $R_i \subseteq Tr \times Tr$ for all $i \in N$ with $i \leq l(\pi)$, satisfying the four conditions of Definition 12. Pick any $t' \in Tr$ with $t R_{i+1} t'$ such a $t'$ must exist by Definition 8. Now $source(t') = p'_i$. By Definition 8, $t' \in Tr^*$ and $\ell(t') = \ell(t) \notin B$. It remains to show that $t' \sim_{\rho'} \hat{\rho'}$ for each finite prefix $\rho'$ of the suffix $p'_i u'_i p'_{i+1} u'_{i+1} p'_{i+2} \ldots$ of $\pi'$. This follows by Lemma 13. \hfill $\blacktriangle$

### 4 Stating and Verifying Liveness Properties

The main purpose of ep-bisimilarity is as a vehicle for proving liveness properties. A **liveness property** is any property saying that eventually something good will happen [16]. Liveness properties are **linear-time properties**, in the sense that they are interpreted primarily on the (complete) runs of a system. When a distributed system is formalised as a state in an (extended) LTS, a run of the distributed system is modelled as a path in the transition system, starting from that state. However, not every such path models a realistic system run. A **completeness criterion** [9] selects some of the paths of a system as **complete paths**, namely those that model runs of the represented system.

A state $s$ in an (extended) LTS is said to satisfy a linear time property $\varphi$ when employing the completeness criterion $CC$, notation $s \models^{CC} \varphi$, if each complete run of $s$ satisfies $\varphi$ [10]. Writing $\pi \models \varphi$ when property $\varphi$ holds for path $\pi$, we thus have $s \models^{CC} \varphi$ if $\pi \models \varphi$ for all complete paths $\pi$ starting from $s$. When simplifying a system $s$ into an equivalent system $s'$, so that $s \sim s'$ for some equivalence relation $\sim$, it is important that judgements $\models^{CC} \varphi$ are preserved:

$$s \sim s' \Rightarrow (s \models^{CC} \varphi \iff s' \models^{CC} \varphi).$$

This is guaranteed when for each path $\pi$ of $s$ there exists a path $\pi'$ of $s'$, such that (a) $\pi \models \varphi$ if $\pi' \models \varphi$, and (b) $\pi'$ is complete if $\pi$ is complete. Here (a) is already guaranteed when $\pi$ and $\pi'$ are related by strong bisimilarity. Taking $CC$ to be $B$-justness for any classification of a set of actions $B$ as blocking, and $\sim$ to be $\trianglelefteq_{ep}$, Theorem 14 now ensures (b) as well.
5 Interpreting Justness in Process Algebras

Rather than using LTSs directly to model distributed systems, one usually employs other formalisms such as process algebras or Petri nets, for they are often easier to use for system modelling. Their formal semantics maps their syntax into states of LTSs. In this section we introduce the Algebra of Broadcast Communication with discs and Emissions (ABCdE), an extension of Milner’s Calculus of Communication Systems (CCS) [17] with broadcast communication and signal emissions. In particular, we give a structural operational semantics [18] that interprets process expressions as states in an LTS. Subsequently, we define the successor relation $\leadsto$ for ABCdE, thereby enriching the LTS into an LTSS.

We use ABCdE here, as for many realistic applications CCS is not expressive enough [7, 11]. The presented approach can be applied to a wide range of process algebras. ABCdE is designed to be a starting point for transferring the presented theory to algebras used for ‘real’ applications. For example, broadcast communication is needed for verifying routing protocols (e.g. [14]); signals are employed to correctly render and verify protocols for mutual exclusion [11, 3]. Another reason is that broadcasts as well as signals, in different ways, give rise to asymmetric concurrency relations, and we want to show that our approach is flexible enough to handle this.

5.1 Algebra of Broadcast Communication with Discards and Emissions

ABCdE is parametrised with sets $\mathcal{A}$ of agent identifiers, $\mathcal{C}$ of handshake communication names, $\mathcal{B}$ of broadcast communication names, and $\mathcal{I}$ of signals; each $A \in \mathcal{A}$ comes with a defining equation $A \overset{\mathcal{C}}{=} P$ with $P$ being a guarded ABCdE expression as defined below. $\mathcal{C} := \{\bar{c} \mid c \in \mathcal{C}\}$ is the set of handshake communication co-names, and $\mathcal{I} := \{s \mid s \in \mathcal{I}\}$ is the set of signal emissions. The collections $\mathcal{B}!$, $\mathcal{B}?$, and $\mathcal{B}$: broadcast, receive, and discard actions are given by $\mathcal{B}! := \{b! \mid b \in \mathcal{B}\}$ for $\bar{z} \in \{!?, ?\}$. $Act := \mathcal{C} \cup \mathcal{C} \cup \{\tau\} \cup \mathcal{B}! \cup \mathcal{B}? \cup \mathcal{I}$ is the set of actions, where $\tau$ is a special internal action. $L := Act \cup \mathcal{B}! \cup \mathcal{B}? \cup \mathcal{I}$ is the set of transition labels. Complementation extends to $\mathcal{C} \cup \mathcal{C} \cup \mathcal{I} \cup \mathcal{I}$ by $\bar{c} := c$.

Below, $c$ ranges over $\mathcal{C}\cup\mathcal{C}\cup\mathcal{I}\cup\mathcal{I}$, $\eta$ over $\mathcal{C}\cup\mathcal{C}\cup\{\tau\} \cup \mathcal{I} \cup \mathcal{I}$, $\alpha$ over $Act$, $\ell$ over $L$, $b$ over $\mathcal{B}, \bar{z}, \bar{z}_1, \bar{z}_2$ over $\{!?, ?\}$ and $s, r$ over $\mathcal{I}$. A relabelling is a function $f : (\mathcal{C} \rightarrow \mathcal{C}) \cup (\mathcal{B} \rightarrow \mathcal{B}) \cup (\mathcal{I} \rightarrow \mathcal{I})$; it extends to $L$ by $f(\bar{c}) = \overline{f(c)}$, $f(\tau) := \tau$, and $f(b!) = f(b?)$.

The set $P$ of ABCdE expressions or processes is the smallest set including:

| Symbols | Meaning |
|---------|---------|
| $0$ | inaction |
| $P + Q$ for $P, Q \in P$ | $\alpha.P$ for $\alpha \in Act$ and $P \in P$ | action prefixing |
| $P|L$ for $L \subseteq \mathcal{C} \cup \mathcal{I}$, $P \in P$ | $P|Q$ for $P, Q \in P$ | parallel composition |
| $A$ for $A \in \mathcal{A}$ | $P\{c\}$ for $P$ a relabelling, $P \in P$ | relabelling |

We abbreviate $\alpha.0$ by $\alpha$, and $P\{c\}$ by $P|c$. An expression is guarded if each agent identifier occurs within the scope of a prefixing operator.

The semantics of ABCdE is given by the labelled transition relation $\rightarrow \subseteq P \times L \times P$, where transitions $P \xrightarrow{\ell} Q$ are derived from the rules of Tables 1–3. Here $\mathcal{L} := \{\bar{c} \mid c \in L\}$.

Table 1 shows the basic operational semantics rules, identical to the ones of CCS [17]. The process $\alpha.P$ performs the action $\alpha$ first and subsequently acts as $P$. The choice operator $P + Q$ may act as either $P$ or $Q$, depending on which of the processes is able to act at all. The parallel composition $P|Q$ executes an action $\eta$ from $P$, an action $\eta$ from $Q$, or in the case where $P$ and $Q$ can perform complementary actions $c$ and $\bar{c}$, the process can perform a synchronisation, resulting in an internal action $\tau$. The restriction operator $P\{c\}$ inhibits execution of the actions from $L$ and their complements. The relabelling $P[\ell]$ acts like process $P$ with all labels $\ell$ replaced by $f(\ell)$. Finally, an agent $A$ can do the same actions as the body...
Enabling Preserving Bisimulation Equivalence

Table 1 Structural operational semantics of ABCdE – Basic

| Rule | Abbreviation | Description |
|------|--------------|-------------|
| \(\alpha.P \xrightarrow{\alpha} P\) | (ACT) | \(P \xrightarrow{\alpha} P'\) if and only if \(P = P'\) |
| \(P \xrightarrow{\eta} P'\) | (PAR-L) | \(P\) is parallel to \(P'\) |
| \(P \xrightarrow{\varphi} P'\) | (COM) | \(P\) is commutative, \(P = P'\) |
| \(P \xrightarrow{\eta} P'\) | (PAR-R) | \(P\) is parallel to \(P'\) |
| \(P \xrightarrow{\eta} P'\) | (DIS-NIL) | \(P\) is a nil process |
| \(P \xrightarrow{\eta} P'\) | (DIS-SUM) | \(P\) is a sum of processes |
| \(P \xrightarrow{\eta} P'\) | (DIS-REC) | \(P\) is a recursive process |

\(P\) of its defining equation. When we take \(\mathcal{R} = \mathcal{F} = \emptyset\), only the rules of Table 1 matter, and ABCdE simplifies to CCS.

Table 2 augments CCS with a mechanism for broadcast communication. The rules are similar to the ones for the Calculus of Broadcasting Systems (CBS) [19]; they also appear in the process algebra ABC [12], a strict subalgebra of ABCdE. The Rule (Bro) presents the core of broadcast communication, where any broadcast-action \(b!\) performed by a component in a parallel composition is guaranteed to be received by any other component that is ready to do so, i.e., in a state that admits a \(b!\)-transition. Since it is vital that the sender of a broadcast can always proceed with it, regardless of the state of other processes running in parallel, the process algebra features discard actions \(b\), in such a way that each process in any state can either receive a particular broadcast \(b\), by performing the action \(b\), or discard it, by means of a \(b\), but not both. A broadcast transmission \(b!\) can synchronise with either \(b\) or \(b\), and thus is never blocked by lack of a listening party. In order to ensure associativity of the parallel composition, one requires rule (Bro) to consider receipt at the same time (\(\sharp_1 = \sharp_2 = ?\)). The remaining four rules of Table 2 generate the discard-actions. The Rule (Dis-NIL) allows the nil process (inaction) to discard any incoming message; in the same spirit (Dis-ACT) allows a message to be discarded by a process that cannot receive it. A process offering a choice can only perform a discard-action if neither choice-option can handle it (Rule (Dis-SUM)). Finally, an agent \(A\) can discard a broadcast iff the body \(P\) of its defining equation can discard it. Note that in all these cases a process does not change state by discarding a broadcast.

There exists a variant of CBS, ABC and ABCdE without discard actions, see [12, 9]. This approach, however, features negative premises in the operational rules. As a consequence, the semantics are not in De Simone format [22]. Making use of discard actions and staying within the De Simone format allows us to use meta-theory about this particular format. For example we know, without producing our own proof, that the operators \(+\) and \(|\) of ABC and ABCdE are associative and commutative, up to strong bisimilarity [2]. Moreover, strong bisimilarity [17] is a congruence for all operators of ABCdE.

Next to the standard operators of CCS and a broadcast mechanism, ABCdE features also signal emission. Informally, the signalling operator \(P^s\) emits the signal \(s\) to be read by another process. Signal emissions cannot block other actions of \(P\). Classical examples are
The operational semantics of ABCdE presented in Section 5.1 interprets the language as an LTS. In Section 5.3, we aim to extend this LTS into an LTSS by defining a successor relation \( \rightarrow \), and thereby also a concurrency relation \( \rightarrow \). In case a process performs a 'proper' action, the signal emission ceases (Rule (Act-sig)), but if the process performs a broadcast discard transition, it does not (Rule (Dis-sig)).

The presented semantics stays within the realm of the De Simone format [22], which brings many advantages. However, there exists an alternative, equivalent semantics, which is based on predicates. Rather than explicitly modelling the state of the emitting process. Other operators, such as relabelling and restriction do not perform a broadcast discard transition, it does not (Rule (Dis-sig)).

The full semantics can be found in [3]. Some readers might find this notation more intuitive as signal emitting processes do not perform an actual action when a component reads the emitted signal.

### 5.2 Naming Transitions

The operational semantics of ABCdE presented in Section 5.1 interprets the language as an LTS. In Section 5.3, we aim to extend this LTS into an LTSS by defining a successor relation \( \rightarrow \) on the transitions, and thereby also a concurrency relation \( \rightarrow \). However, the standard interpretation of CCS-like languages, which takes as transitions the triples \( \bar{P} \rightarrow \bar{P}' \), does not work for our purpose.

#### Example 15.
Let \( P = A|B \) with \( A \overset{\text{def}}{=} \tau.A + a.A \) and \( B \overset{\text{def}}{=} \bar{a}.B \). Now the transition \( P \overset{\tau}{\rightarrow} P \) arises in two ways; either as a transition solely of the left component, or as a synchronisation between both components. The first form of that transition is concurrent with the transition \( P \overset{a}{\rightarrow} P \), but the second is not. In fact, an infinite path that would only perform the \( \tau \)-transition stemming from the left component would not be just, whereas a path that schedules both \( \tau \)-transitions infinitely often is. This shows that we want to distinguish these two \( \tau \)-transitions, and hence not see a transition as a triple \( P \overset{\alpha}{\rightarrow} Q \).

Instead, we take as the set \( \text{Tr} \) of transitions in our LTSS the derivations of the transition triples \( P \overset{\alpha}{\rightarrow} Q \) from our operational rules. This is our reason to start with a definition of an LTS that features transitions as a primitive rather than a derived concept.

#### Definition 16 (Derivation).
A derivation of a transition triple \( \varphi \) is a well-founded (without infinite paths that keep going up), ordered, upwardly branching tree with the nodes labelled by transition triples, such that
1. the root is labelled by $\varphi$, and
2. if $\mu$ is the label of a node and $K$ is the sequence of labels of this node’s children then $\frac{K}{\mu}$ is a substitution instance of a rule from Tables 1–3.

(a) Given a derivation, we refer to the subtrees obtained by deleting the root node as its direct subderivations. Furthermore, by definition, $\frac{K}{\varphi}$ is a substitution instance of a rule, where $\varphi$ is the label of the derivation’s root and $K$ is the sequence of labels of the root’s children; the derivation is said to be obtained by this rule.

We interpret ABCdE as an LTS $(S, Tr, source, target, t)$ by taking as states $S$ the ABCdE expressions $P$ and as transitions $Tr$ the derivations of transition triples $P \rightarrow Q$. Given a derivation $t$ of a triple $P \rightarrow Q$, we define its label $\ell(t) := \alpha$, its source $source(t) := P$, and its target $target(t) := Q$.

Definition 17 (Name of Derivation). The derivation obtained by application of $(Act)$ is called $\alpha.P$. The derivation obtained by application of $(Com)$ or $(Brk)$ is called $t[u$, where $t, u$ are the names of its direct subderivations. The derivation obtained by application of $(Par-l)$ is called $t(Q)$ where $t$ is the direct subderivation’s name and $Q$ is the process on the right hand side of $|$ in the derivation’s source. In the same way, the derivation obtained by application of $(Par-r)$ is called $P[t$, while $(SUM-l), (SUM-r), (Res), (Rel), and (Rec)$ yield $t+Q, P+t, t\cdot L, t[f]$ and $A:t$, where $t$ is the direct subderivation’s name. The remaining four rules of Table 2 yield $b\cdot 0, b:\alpha.P, t+u$ and $A:t$, where $t, u$ are direct subderivations’ names. The derivation of $P's$ $\overset{\delta}{\rightarrow} P's$ obtained by $(Sig)$ is called $P^{\rightarrow^* \delta}$. Rules $(Act-sig)$, $(Dis-sig)$ and $(Sig-sig)$ yield $t\cdot r$, and rules $(SUM-SUM-l), (SUM-SUM-r)$ and $(Sig-rec)$ yield $t+Q, P+t$ and $A:t$, where $t$ is the direct subderivation’s name.

We interpret ABCdE as an LTS $(S, Tr, source, target, t)$ by taking as states $S$ the ABCdE expressions $P$ and as transitions $Tr$ the derivations of transition triples $P \rightarrow Q$. Given a derivation $t$ of a triple $P \rightarrow Q$, we define its label $\ell(t) := \alpha$, its source $source(t) := P$, and its target $target(t) := Q$.

A derivation’s name reflects the syntactic structure of that derivation. The derivations’ names not only provide a convenient way to identify derivations but also highlight the compositionality of derivations. For example, given a derivation $t$ of $P \rightarrow Q$ and a derivation $u$ of $Q \rightarrow Q'$ with $c \in C \cup \mathcal{E} \cup \mathcal{F} \cup \mathcal{G}$, $t[u$ will be a derivation of $P|Q \rightarrow P'|Q'$.

Hereafter, we refer to a derivation of a transition triple as a ‘transition’.

5.3 Successors

In this section we extend the LTS of ABCdE into an LTSS, by defining the successor relation $\sim$. For didactic reasons, we do so first for CCS, and then extend our work to ABCdE.

Note that $\chi \sim_\zeta \chi'$ can hold only when $source(\chi) = source(\zeta)$, i.e., transitions $\chi$ and $\zeta$ are both enabled in the state $O := source(\chi) =$ source(\zeta). It can thus be defined by structural induction on $O$. The meaning of $\chi \sim_\zeta \chi'$ is (a) that $\chi$ is unaffected by $\zeta$ – denoted $\chi \sim \zeta$ – and (b) that when doing $\zeta$ instead of $\chi$, afterwards a variant $\chi'$ of $\chi$ is still enabled. Restricted to CCS, the relation $\sim$ is moreover symmetric, and we can write $\chi \sim \zeta$.

In the special case that $O = \emptyset$ or $O = \alpha.Q$, there are no two concurrent transitions enabled in $O$, so this yields no triples $\chi \sim_\zeta \chi'$. When $O = P + Q$, any two concurrent transitions $\chi \sim \zeta$ enabled in $O$ must either stem both from $P$ or both from $Q$. In the former case, these transitions have the form $\chi = t + Q$ and $\zeta = v + Q$, and we must have $t \sim v$, in the sense that $t$ and $v$ stem from different parallel components within $P$. So $t \sim_v t'$ for $t \neq u \implies t[u \neq u][t]$.
some transition \( t' \). As the execution of \( \zeta \) discards the summand \( Q \), we also obtain \( \chi \sim_\zeta t' \).

This motivates Item 1 in Definition 18 below. Item 2 follows by symmetry.

Let \( O = P|Q \). One possibility for \( \chi \sim_\zeta \chi' \) is that \( \chi \) comes from the left component and \( \zeta \) from the right. So \( \chi \) has the form \( tQ + \zeta = P|w \). In that case \( \chi \) and \( \zeta \) must be concurrent: we always have \( \chi \sim \zeta \). When doing \( w \) on the right, the left component does not change, and afterwards \( t \) is still possible. Hence \( \chi \sim_\zeta t|\text{target}(w) \). This explains Item 3 in Definition 18.

Another possibility is that \( \chi \) and \( \zeta \) both stem from the left component. In that case \( \chi = tQ \) and \( \zeta = v|w \), and it must be that \( t \sim u \) within the left component. Thus \( t \sim_v t' \) for some transition \( t' \), and we obtain \( \chi \sim_\zeta t'|Q \). This motivates the first part of Item 4.

It can also happen that \( \chi \) stems form the left component, whereas \( \zeta \) is a synchronisation, involving both components. Thus \( \chi = tQ \) and \( \zeta = v|w \). For \( \chi \sim_\zeta \zeta \) to hold, it must be that \( t \sim v \), whereas the \( w \)-part of \( \zeta \) cannot interfere with \( t \). This yields the second part of Item 4.

The last part of Item 4 is explained in a similar vain from the possibility that \( \zeta \) stems from the left while \( \chi \) is a synchronisation of both components. Item 5 follows by symmetry.

In case both \( \chi \) and \( \zeta \) are synchronisations involving both components, i.e., \( \chi = t|u \) and \( \zeta = v|w \), it must be that \( t \sim v \) and \( u \sim w \). Now the resulting variant \( \chi' \) of \( \chi \) after \( \zeta \) is simply \( t'|u' \), where \( t \sim_v t' \) and \( u \sim_u u' \). This underpins Item 6.

If \( O \) has the form \( P[f] \), \( \chi \) and \( \zeta \) must have the form \( t[f] \) and \( v[f] \), respectively. Whether \( t \) and \( v \) are concurrent is not influenced by the renaming operator. So \( t \sim v \). The variant of \( t \) that remains after doing \( v \) is also not affected by the renaming, so if \( t \sim_v t' \) then \( \chi \sim_\zeta t'[f] \). The case that \( O \) has the form \( P \times L \) is equally trivial. This yields the first two parts of Item 7.

In case \( O = A \) with \( A \not\sim P \), then \( \chi \) and \( \zeta \) must have the forms \( A \times t \) and \( A \times v \), respectively, where \( t \) and \( v \) are enabled in \( P \). Now \( \chi \sim_\zeta \zeta \) only if \( t \sim v \), so \( t \sim_v t' \) for some transition \( t' \). As the recursion around \( P \) disappears upon executing \( \zeta \), we obtain \( \chi \sim_\zeta t' \). This yields the last part of Item 7. Together, this motivates the following definition.

\begin{definition}[Successor Relation for CCS] \label{def:successor}

The relation \( \sim \subseteq Tr \times Tr \times Tr \) is the smallest relation satisfying

1. \( t \sim_v t' \) implies \( t + Q \sim_{v+Q} t' \),
2. \( u \sim_w u' \) implies \( P + u \sim_{P+w} u' \),
3. \( tQ \sim_{P|w} (t|\text{target}(u)) \) and \( P[u \sim_v Q] \ (\text{target}(v)) \),
4. \( t \sim_v t' \) implies \( tQ \sim_{v|Q} t'|Q \), \( tQ \sim_{v|w} (t'|\text{target}(w)) \) and \( t|u \sim_v Q t'|u \),
5. \( u \sim_w u' \) implies \( P|u \sim_{P+u} P|u' \), \( P[u \sim_v Q] \ u' \), and \( t|u \sim_v Q t'|u' \),
6. \( t \sim_v t' \land u \sim_w u' \) implies \( t|u \sim_v w t'|u' \),
7. \( t \sim_v t' \) implies \( t\times L \sim_{v\times L} t'|L, t[f] \sim_{v[f]} t'|f \) and \( A \times t \sim_{A \times v} t' \).

for all \( t, t', u, u', v, w \in Tr, P, Q \in \mathcal{P} \) and \( L, f, A \) with \( \text{source}(t) = \text{source}(v) = P, \text{source}(u) = \text{source}(w) = Q, \text{source}(t') = \text{target}(v), \text{source}(u') = \text{target}(w), L \subseteq \mathcal{C}, f \) a relabelling and \( A \in \mathcal{A} \) - provided that the composed transitions exist.

By projecting the ternary relation \( \sim \) on its first two components, we obtain a characterisation of the concurrency relation \( \sim \) between CCS transitions:

\begin{observation}[Concurrency Relation for CCS] \label{obs:concurrency}

The relation \( \sim \subseteq Tr \times Tr \) is the smallest relation satisfying

1. \( t \sim v \) implies \( t + Q \sim v + Q \),
2. \( u \sim w \) implies \( P + u \sim P + w \),
3. \( t|Q \sim_{P|w} w | P|u \sim_P Q | t Q \)
4. \( t \sim v \) implies \( t|Q \sim v|Q, t|Q \sim v|w, \) and \( t|u \sim v|Q \),
Enabling Preserving Bisimulation Equivalence

5. \( u \sim w \) implies \( P|u \sim P|w, P|u \sim v|w \), and \( t|u \sim P|w \),
6. \( t \sim v \land u \sim w \) implies \( t|u \sim v|w \),
7. \( t \sim v \) implies \( t\L \sim v\L, t[f] \sim v[f] \) and \( A.t \sim A.v \),
for all \( t, u, v, w \in T_r, P, Q \in \mathcal{P} \) and \( L, f, A \) with \( \text{source}(t) = \text{source}(v) = P, \text{source}(u) = \text{source}(w) = Q, L \subseteq \mathcal{C} \), \( f \) a relabelling and \( A \in \mathcal{A} \) – provided that the composed transitions exist.

The same concurrency relation appeared earlier in [12]. Definition 18 and Observation 19 implicitly provide SOS rules for \( \sim \) and \( \sim' \), such as \( \frac{t \sim' v'}{t \sim Q \sim v' Q} \). It is part of future work to investigate a rule format for ep-bisimilarity.

Definition 20 below generalises Definition 18 to all of ABCdE. In the special case that \( \zeta \) is a broadcast discard or signal emission, i.e., \( \ell(\zeta) \in \mathcal{B} \cup \mathcal{F} \), the transition \( \zeta \) does not change state – we have \( \text{source}(\zeta) = \text{target}(\zeta) = O \) – and is supposed not to interfere with any other transition \( \chi \) enabled in \( O \). Hence \( \chi \sim \zeta \) and \( \chi \sim'_\zeta \chi \). This is Item 1 from Definition 20.

Consequently, in Item 11, which corresponds to Item 7 from Definition 18, we can now safely restrict attention to the case \( \ell(\zeta) \in \text{Act} \). The last part of that item says that if within the scope of a signalling operator an action \( v \) occurs, one escapes from this signalling context, similarly to the cases of choice and recursion. That would not apply if \( v \) is a broadcast discard or signal emission, however.

An interesting case is when \( \chi \) is a broadcast receive or discard transition, i.e., \( \ell(\chi) = b? \) or \( b\cdot \). We postulate that one can never interfere with such an activity, as each process is always able to synchronise with a broadcast action, either by receiving or by discarding it. So we have \( \chi \sim \zeta \) for all \( \zeta \) with \( O = \text{source}(\zeta) = \text{source}(\chi) \). It could be, however, that in \( \chi \sim'_\zeta \chi' \), one has \( \ell(\chi) = b? \) and \( \ell(\chi') = b, \) or vice versa. Item 2 says that if \( O = \alpha.P, \) with \( \zeta \) the \( \alpha \)-transition to \( P \), then \( \chi' \) can be any transition labelled \( b? \) or \( b \cdot \) that is enabled in \( P \). The second parts of Items 3 and 4 generalise this idea to discard actions enabled in a state of the form \( P + Q \). Finally, Items 5 and 6 state that when \( \chi \) is a broadcast receive stemming from the left side of \( O = P + Q \) and \( \zeta \) an action from the right, or vice versa, then \( \chi' \) may be any transition labelled \( b? \) or \( b \cdot \) that is enabled in \( target(\zeta) \). In all other cases, successors of \( \chi \) are inherited from successors of their building block, similar to the cases of other transitions.

Definition 20 (Successor Relation for ABCdE). The relation \( \sim \subseteq T_r \times T_r \times T_r \) is the smallest relation satisfying

1. \( \ell(\zeta) \in \mathcal{B} \cup \mathcal{F} \) and \( \text{source}(\zeta) = \text{source}(\chi) \) implies \( \chi \sim \zeta \chi \),
2. \( \ell(t) \in \{b?, b\cdot\} \) implies \( b?P \sim v?_{v?}P \) \( t \) and \( b\cdotP \sim _{v?}P \) \( t \),
3. \( \ell(v) \notin \mathcal{F} \) and \( t \sim_v t' \) implies \( t + Q \sim v+Q t' \) and \( t + u \sim v+Q t' \),
4. \( \ell(\alpha) \notin \mathcal{F} \) and \( u \sim w u' \) implies \( P + u \sim p+w u' \) and \( t + u \sim p+w u' \),
5. \( \ell(v) \notin \mathcal{F} \) and \( \ell(t) = b? \land \ell(t') \in \{b?, b\cdot\} \) implies \( t + Q \sim p+w t' \),
6. \( \ell(v) \notin \mathcal{F} \) and \( \ell(u) = b? \land \ell(t') \in \{b?, b\cdot\} \) implies \( P + u \sim v+Q t' \),
7. \( \ell(Q) \sim p_{\sim}P \) \( (t|\text{target}(w)) \) and \( P|u \sim v_{\sim}Q \) \( (\text{target}(v)|u) \),
8. \( t \sim_v t' \) implies \( t|Q \sim v_{\sim}Q t'|Q, t|Q \sim v_{\sim}w \) \( (t'|\text{target}(w)) \), and \( t|u \sim v_{\sim}Q t'|u, \)
9. \( u \sim w u' \) implies \( P|u \sim p_{\sim}P|u', P|u \sim v_{\sim}w \) \( (\text{target}(v)|u') \), and \( t|u \sim p_{\sim}P|u', \)
10. \( t \sim_v t' \land u \sim w u' \) implies \( t|u \sim v_{\sim}w t'|u' \),
11. \( \ell(t) \in \text{Act} \) and \( t \sim_v t' \) implies \( t|L \sim v|L t'|L, t[f] \sim v[f] t'[f] \), \( A.t \sim A.v t' \) and \( t\cdot r \sim v\cdot r t' \),
for all \( t, t', u, u', v, w \in T_r, P, Q \in \mathcal{P} \) and \( \alpha, L, f, A, b, r \) with \( \text{source}(t) = \text{source}(v) = P, \text{source}(u) = \text{source}(w) = Q, \text{source}(t') = \text{target}(v) \) and \( \text{source}(u') = \text{target}(w) \), \( \alpha \in \text{Act} \), \( L \subseteq \mathcal{C} \cup \mathcal{F} \), \( f \) a relabelling, \( A \in \mathcal{A} \), \( b \in \mathcal{B} \) and \( r \in \mathcal{F} \) – provided that the composed transitions exist.
Although we have chosen to inductively define the $\sim$ relations, in Appendix B we follow a different approach in which Definition 20 appears as a theorem rather than a definition. Following [9], we understand each transition as the synchronisation of a number of elementary particles called synchrons. Then relations on synchrons are proposed in terms of which the $\sim$ relation is defined. That this leads to the same result indicates that the above definition is more principled than arbitrary.

### 5.4 Congruence and Other Basic Properties of Ep-bisimilarity

As mentioned before, the operators $+$ and $|$ are associative and commutative up to strong bisimilarity. We can strengthen this result.

**Theorem 21.** The operators $+$ and $|$ are associative and commutative up to $\equiv_{ep}$.

**Proof.** Remember that $\mathbb{P}$ denotes the set of ABCdE expressions or processes. 

**Commutativity of $+$, i.e., $P + Q \equiv_{ep} Q + P$:** The relation

$$\{(I, I, Id_I) \mid I \in \mathbb{P}\} \cup \{(P + Q, Q + P, R_{P,Q}) \mid P, Q \in \mathbb{P}\}$$

is an ep-bisimulation. Here $Id_I := \{(t, t) \mid t \in en(I)\}$ and

$$R_{P,Q} := \{(t + Q, Q + t) \mid t \in en(P) \land t \in \mathbb{B} \} \cup \{(P + u, u + P) \mid u \in en(Q) \land u \notin \mathbb{B}\} \cup \{(t + u, u + t) \mid t \in en(P) \land u \in en(Q) \land t \in \mathbb{B}\}.$$  

$R_{P,Q}$ relates transitions, i.e., derivations of transition triples, that are composed of the same sets of direct subderivations, even though their order is reversed.

**Associativity of $+$, i.e., $(O + P) + Q \equiv_{ep} O + (P + Q)$:** The relation

$$\{(I, I, Id_I) \mid I \in \mathbb{P}\} \cup \{(O + P) + Q, O + (P + Q), R_{O,P,Q}) \mid O, P, Q \in \mathbb{P}\}$$

is an ep-bisimulation. Here $Id_I$ and $R_{O,P}$ are defined similarly to the previous case.

**Commutativity of $|$ , i.e., $P|Q \equiv_{ep} Q|P$:** The relation

$$\{(P|Q, Q|P, R_{P,Q}) \mid P, Q \in \mathbb{P}\}$$

is an ep-bisimulation. Here

$$R_{P,Q} = \{(t|Q, Q|t) \mid t \in en(P) \land t \in \mathbb{B}\} \cup \{(P|u, u|P) \mid u \in en(Q) \land u \notin \mathbb{B}\} \cup \{(t|u, u|t) \mid t \in en(P) \land u \in en(Q) \land \exists b \in \mathbb{B}: \{t|u, u|t\} \in \{\{b\}, \{b, b\}, \{b\}, \{b\}, \{b\}\} \}.$$  

**Associativity of $|$ , i.e., $(O|P)|Q \equiv_{ep} O|(P|Q)$:** The relation

$$\{(O|P)|Q, O|(P|Q), R_{O,P,Q}) \mid O, P, Q \in \mathbb{P}\}$$

is an ep-bisimulation, where $R_{O,P}$ is defined similarly to the previous case. 

Additionally, not only strong bisimilarity should be a congruence for all operators of ABCdE – which follows immediately from the De Simone format – but also our new ep-bisimilarity. This means that if two process terms are ep-bisimilar, then they are also ep-bisimilar in any context.
Enabling Preserving Bisimulation Equivalence

Theorem 22. Ep-bisimilarity is a congruence for all operators of ABCdE.

We cannot get it directly from the existing meta-theory on structural operational semantics, as nobody has studied ep-bisimilarity before. As is standard, the proof is a case distinction on the type of the operator. For example, the case for action prefixing requires

\[ P \simeq_{ep} Q \Rightarrow \alpha.P \simeq_{ep} \alpha.Q \text{ for } \alpha \in \text{Act}. \]

Such properties can be checked by inspecting the syntactic form of the transition rules, using structural induction. While proofs for some statements, such as the one for action prefixing, are merely a simple exercise, others require more care, including long and tedious case distinctions. A detailed proof of Theorem 22 can be found in Appendix A.

6 Failed Alternatives for Ep-Bisimulation

On an LTSS \((S, Tr, source, target, t, \sim)\) an ep-bisimulation has the type \(S \times S \times P(Tr \times Tr)\). This is different from that of other classical bisimulations, which have the type \(S \times S\). While developing ep-bisimulation we have also explored dozens of other candidates, many of them being of type \((S \times S) \cup (Tr \times Tr)\). The inclusion of a relation between transitions is necessary to reflect the concept of components or concurrency in one way or the other. One such candidate definition declares a relation \(R \subseteq (S \times S) \cup (Tr \times Tr)\) a valid bisimulation iff the set of triples

\[ \{(p, q, R) \mid (p, q) \in R \cap (S \times S) \land R = R \cap (en(p) \times en(q))\} \]

is an ep-bisimulation. However, neither this candidate nor any of the others leads to a transitive notion of bisimilarity. The problem stems from systems, not hard to model in ABCdE, with multiple paths \(\pi_i\) from states \(p\) to \(p'\), such that a triple \((p, q, R)\) in an ep-bisimulation \(R\) forces triples \((p', q', R')\) to be in \(R\) for multiple relations \(R_i \subseteq en(p') \times en(q')\), depending on the chosen path \(\pi_i\).

7 Related Work

Our LTSSs generalise the concurrent transition systems of [23]. There \(t \sim_v u\) is written as \(t \uparrow v = u\), and \(\uparrow\) is a partial function rather than a relation, in the sense that for given \(t\) and \(v\) there can be at most one \(u\) with \(t \uparrow v = u\). This condition is not satisfied by broadcast communication, which is one of the reasons we switched to the notation \(t \sim_v u\). As an example, consider \(b|a, (b? + b?)\). The \(b\)-transition after the \(a\)-transition has two variants, namely \(b\rightarrow 0\) and \((b? + b?)\). Another property of concurrent transition systems that is not maintained in our framework is the symmetry of the induced concurrency relation. Finally, [23] requires that \((v \uparrow t) \uparrow (u \uparrow t) = (v \uparrow u) \uparrow (t \uparrow u)\), the cube axiom, whereas we have so far not found reasons to restrict attention to processes satisfying this axiom. We are, however, open to the possibility that for future applications of LTSSs, some closure properties may be imposed on them.

In [1] a location-based bisimulation is proposed. It also keeps track of the components participating in transitions. The underlying model is quite different from ours, which makes it harder to formally argue that this notion of bisimilarity is incomparable to ours. We do not know yet whether it could be used to reason about justness.
8 Conclusion and Future Work

In related work, it has been argued that fairness assumptions used for verifying liveness properties of distributed systems are too strong or unrealistic [13, 4, 12]. As a consequence, justness, a minimal fairness assumption required for the verification of liveness properties, has been proposed. Unfortunately, all classical semantic equivalences, such as strong bisimilarity, fail to preserve justness.

In this paper, we have introduced labelled transition systems augmented by a successor relation, and, based on that, the concept of enabling preserving bisimilarity, a finer variant of strong bisimilarity. We have proven that this semantic equivalence is a congruence for all classical operators. As it also preserves justness, it is our belief that enabling preserving bisimilarity in combination with justness can and should be used for verifying liveness properties of large-scale distributed systems.

Casually speaking, ep-bisimilarity is strong bisimilarity augmented with the requirement that the relation between enabled transitions is inherited by successor transitions. A straightforward question is whether this feature can be combined with other semantic equivalences, such as weak bisimilarity or trace equivalence.

We have further shown how process algebras can be mapped into LTSSs. Of course, process algebra is only one of many formal frameworks for modelling concurrent systems. For accurately capturing causalities between event occurrences, models like Petri nets [21], event structures [24] or higher dimensional automata [20, 8] are frequently preferable. Part of future work is therefore to develop a formal semantics with respect to LTSSs for these frameworks.

In order to understand the scope of justness in real-world applications, we plan to study systems that depend heavily on liveness. As a starting point we plan to verify locks, such as ticket lock.

A Congruence Proofs

Ep-bisimilarity is a congruence for all operators of ABCdE iff Propositions 23–28 below hold. We prove them one by one.

\textbf{Proposition 23.} If $P \bowtie_{ep} Q$ and $\alpha \in \text{Act}$ then $\alpha.P \bowtie_{ep} \alpha.Q$.

\textbf{Proof.} A transition enabled in $\alpha.P$ is either $\overset{\alpha}{\rightarrow}P$ or $b\alpha.P$ for some $b \in \mathcal{B}$ with $\alpha \neq b$?

Let $\mathcal{R} \subseteq \mathcal{P} \times \mathcal{P} \times \mathcal{P}(\mathcal{Tr} \times \mathcal{Tr})$ be the smallest relation satisfying

1. if $(P, Q, R) \in \mathcal{R}'$ for some ep-bisimulation $\mathcal{R}'$ then $(P, Q, R) \in \mathcal{R}$,
2. if $(P, Q, R) \in \mathcal{R}$ and $\alpha \in \text{Act}$ then $(\alpha.P, \alpha.Q, \alpha.R) \in \mathcal{R}$, where

\[
\alpha.R := \{(\overset{\alpha}{\rightarrow}P, \overset{\alpha}{\rightarrow}Q)\} \cup \{(b\alpha.P, b\alpha.Q) \mid b \in \mathcal{B} \land \alpha \neq b\}.
\]

It suffices to show that $\mathcal{R}$ is an ep-bisimulation. I.e., all entries in $\mathcal{R}$ satisfy the requirements of Definition 8.

\textit{Induction base:} Suppose $(P, Q, R) \in \mathcal{R}'$ for some ep-bisimulation $\mathcal{R}'$. Since $\mathcal{R}' \subseteq \mathcal{R}$, all requirements of Definition 8 are satisfied.

\textit{Induction step:} Suppose $(P, Q, R) \in \mathcal{R}$ satisfies all requirements of Definition 8, we prove that $(P', Q', R')$, where $P' = \alpha.P, Q' = \alpha.Q$, and $R' = \alpha.R$, also satisfies those requirements. This follows directly with Definitions 8 and 20.

\textbf{Proposition 24.} If $P_L \bowtie_{ep} Q_L$ and $P_n \bowtie_{ep} Q_n$ then $P_L + P_n \bowtie_{ep} Q_L + Q_n$.

\textbf{Proof.} A transition enabled in $P + Q$ is either

- $t + Q$ for some $t \in \text{en}(P)$ with $\ell(t) \notin \mathcal{B}$,
- $P + u$ for some $u \in \text{en}(Q)$ with $\ell(u) \notin \mathcal{B}$, or
- $t + u$ for some $t \in \text{en}(P)$ and $u \in \text{en}(Q)$ with $\ell(t) = \ell(u) \in \mathcal{B}$.

Let $\mathcal{R} \subseteq \mathcal{P} \times \mathcal{P} \times \mathcal{P}(\mathcal{Tr} \times \mathcal{Tr})$ be the smallest relation satisfying

1. if $(P, Q, R) \in \mathcal{R}'$ for some ep-bisimulation $\mathcal{R}'$ then $(P, Q, R) \in \mathcal{R}$,
2. if $(P_L, Q_L, R_L), (P_n, Q_n, R_n) \in \mathcal{R}$ then $(P_L + P_n, Q_L + Q_n, R_L + R_n) \in \mathcal{R}$, where

\[
R_L + R_n := \{(t + P_n, v + Q_n) \mid t R_L v \wedge \ell(t) \notin \mathcal{B}\} \cup
\{(P_L + u, Q_L + w) \mid u R_n w \wedge \ell(u) \notin \mathcal{B}\} \cup
\{(t + u, v + w) \mid t R_L v \wedge u R_n w \wedge \ell(t) = \ell(u) \in \mathcal{B}\}.
\]

It suffices to show that $\mathcal{R}$ is an ep-bisimulation. I.e., all entries in $\mathcal{R}$ satisfy the requirements of Definition 8. We proceed by structural induction.

\textit{Induction base:} Suppose $(P, Q, R) \in \mathcal{R}'$ for some ep-bisimulation $\mathcal{R}'$. Since $\mathcal{R}' \subseteq \mathcal{R}$, all requirements of Definition 8 are satisfied.

\textit{Induction step:} Suppose $(P_L, Q_L, R_L), (P_n, Q_n, R_n) \in \mathcal{R}$ satisfy all requirements of Definition 8, we prove that $(P, Q, R)$, where $P = P_L + P_n$, $Q = Q_L + Q_n$, and $R = R_L + R_n$, also satisfies those requirements.

$R \subseteq \text{en}(P) \times \text{en}(Q)$ follows from $R_L \subseteq \text{en}(P_L) \times \text{en}(Q_L)$ and $R_n \subseteq \text{en}(P_n) \times \text{en}(Q_n)$.

\begin{itemize}
  \item \textit{Requirement 1.a:} It suffices to find, for each $\chi \in \text{en}(P)$, a $\zeta \in \text{en}(Q)$ with $\chi R \zeta$.
  \begin{enumerate}
  \item Suppose $\chi = t + P_n$ for some $t \in \text{en}(P_L)$ with $\ell(t) \notin \mathcal{B}$.
      We obtain $v \in \text{en}(Q_L)$ with $t R_L v$, and pick $\zeta = v + Q_n$.
  \item Suppose $\chi = P_n + u$ for some $u \in \text{en}(P_n)$ with $\ell(u) \notin \mathcal{B}$.
      We obtain $w \in \text{en}(Q_n)$ with $u R_n w$, and pick $\zeta = Q_n + w$.
  \end{enumerate}
\end{itemize}
3. Suppose $\chi = t + u$ for some $t \in \text{en}(P_L)$ and $u \in \text{en}(P_R)$ with $\ell(t) = \ell(u) \in \mathcal{B}$.

We obtain $v \in \text{en}(Q_L)$ and $w \in \text{en}(Q_R)$ with $t \stackrel{R}{\rightarrow} v$ and $u \stackrel{R}{\rightarrow} w$, and pick $\zeta = v + w$.

In all cases, $\zeta \in \text{en}(Q)$ and $\chi \stackrel{R}{\rightarrow} \zeta$ hold trivially.

**Requirement 1.b:** The proof is similar to that of Requirement 1.(a) and is omitted.

**Requirement 1.c:** This follows directly from the observations that

- $\ell(t) = \ell(v) \implies \ell(t + P_R) = \ell(v + Q_R)$,
- $\ell(u) = \ell(w) \implies \ell(P_L + u) = \ell(Q_L + w)$,
- $\ell(t) = \ell(v) \land \ell(u) = \ell(w) \implies \ell(t + u) = \ell(v + w)$;

provided that the composed transitions exist.

**Requirement 2:** It suffices to find, for arbitrary $\Upsilon, \Upsilon'$ with $\Upsilon \stackrel{R}{\rightarrow} \Upsilon'$, an $R'$ with $(\text{target}(\Upsilon), \text{target}(\Upsilon'), R') \in \mathcal{R}$, such that

(a) for arbitrary $\chi, \chi'$ with $\chi \stackrel{R}{\rightarrow} \chi'$ and $\chi \sim_\Upsilon \zeta$, we can find a $\zeta'$ with $\chi' \sim_{\Upsilon'} \zeta'$ and $\zeta \stackrel{R'}{\rightarrow} \zeta'$,
(b) for arbitrary $\chi, \chi'$ with $\chi \stackrel{R}{\rightarrow} \chi'$ and $\chi' \sim_{\Upsilon'} \zeta'$, we can find a $\zeta$ with $\chi \sim_\Upsilon \zeta$ and $\zeta \stackrel{R'}{\rightarrow} \zeta'$.

Below we focus merely on (a), as (b) will follow by symmetry.

Suppose $\ell(\Upsilon) \in \mathcal{B} \cup \overline{\mathcal{B}}$. Pick $R' = R$. Then $(\text{target}(\Upsilon), \text{target}(\Upsilon'), R') = (P, Q, R) \in \mathcal{R}$.

From $\chi \sim_\Upsilon \zeta$ we have $\zeta = \chi$. Pick $\zeta' = \chi'$. Then $\chi' \sim_{\Upsilon'} \zeta'$. $\zeta \stackrel{R'}{\rightarrow} \zeta'$ is given by $\chi \stackrel{R}{\rightarrow} \chi'$.

We further split the cases when $\ell(\Upsilon) \in \text{Act}$.

1. Suppose $\Upsilon = v + P_R$ and $\Upsilon' = v' + Q_R$ with $v \stackrel{R}{\rightarrow} v'$. We obtain $R'_v$ that satisfies Requirement 2 with respect to $v$ and $v'$. Pick $R' = R'_v$. Then $(\text{target}(\Upsilon), \text{target}(\Upsilon'), R') = (\text{target}(v), \text{target}(v'), R'_v) \in \mathcal{R}$.

   a. Suppose $\chi = t + P_R$ and $\chi' = t' + Q_R$ with $t \stackrel{R}{\rightarrow} t'$. From $\chi \sim_\Upsilon \zeta$ we have $t \sim_\Upsilon \zeta$.

      Then we obtain $x'$ with $t' \sim_\Upsilon x'$ and $\zeta \stackrel{R}{\rightarrow} x'$. Pick $\zeta' = x'$. Then $\chi' \sim_{\Upsilon'} \zeta'$ follows from $t' \sim_\Upsilon x'$.

   b. Suppose $\chi = P_L + u$ and $\chi' = Q_L + u'$ with $u \stackrel{R}{\rightarrow} u'$. We obtain $x'$ with $\zeta \stackrel{R}{\rightarrow} x'$ and $\chi \sim_\Upsilon x'$. Pick $\zeta' = x'$. Then $\chi' \sim_{\Upsilon'} \zeta'$ follows from $t' \sim_\Upsilon x'$.

   c. Suppose $\chi = P_L + u$ and $\chi' = t' + u'$ with $t \stackrel{R}{\rightarrow} t'$ and $u \stackrel{R}{\rightarrow} u'$. From $\chi \sim_\Upsilon \zeta$ we have $t \sim_\Upsilon \zeta$. Then we obtain $x'$ with $t' \sim_\Upsilon x'$ and $\zeta \stackrel{R}{\rightarrow} x'$. Pick $\zeta' = x'$. Then $\chi' \sim_{\Upsilon'} \zeta'$ follows from $t' \sim_\Upsilon x'$.

   In all cases, $\zeta \stackrel{R}{\rightarrow} \zeta'$ is given by $\zeta \stackrel{R}{\rightarrow} x'$.

2. Suppose $\Upsilon = P_L + w$ and $\Upsilon' = Q_L + w$ with $w \stackrel{R}{\rightarrow} w'$. The proof is similar to that of the previous case.

\[\square\]

**Proposition 25.** If $P_L \otimes_{ep} Q_L$ and $P_R \otimes_{ep} Q_R$ then $P_L | P_R \otimes_{ep} Q_L | Q_R$.

**Proof.** A transition enabled in $P|Q$ is either

- $t|Q$ for some $t \in \text{en}(P)$ with $\ell(t) \notin \mathcal{B} \cup \overline{\mathcal{B}} \cup \mathcal{B}$;
- $P|u$ for some $u \in \text{en}(Q)$ with $\ell(u) \notin \mathcal{B} \cup \overline{\mathcal{B}} \cup \mathcal{B}$;
- $t|u$ for some $t \in \text{en}(P)$ and $u \in \text{en}(Q)$ with $\ell(t) = \ell(u) \in \mathcal{C} \cup \overline{\mathcal{C}} \cup \mathcal{E} \cup \overline{\mathcal{E}}$, or
- $t|u$ for some $t \in \text{en}(P)$ and $u \in \text{en}(Q)$ with $\ell(t), \ell(u) \in \{b, b^2 \}, \{b^3, b^4, \} \{b^5, b^6, \}$, for some $b \in \mathcal{B}$.

Let $\mathcal{R} \subseteq \mathcal{P} \times \mathcal{P} \times \mathcal{P}(Tr \times Tr)$ be the smallest relation satisfying

1. if $(P, Q, R) \in \mathcal{R}$ for some ep-bisimulation $\mathcal{R}$ then $(P, Q, R) \in \mathcal{R}$,
2. if \((P_\ell, Q_\ell, R_\ell), (P_n, Q_n, R_n) \in \mathcal{R}\) then \((P_\ell \cdot P_n, Q_\ell \cdot Q_n, R_\ell \cdot R_n) \in \mathcal{R}\), where

\[
R_\ell \cdot R_n := \{(t(P_\ell, v(Q_n)) \mid t \in R_\ell, v \in R_n \}
\cup
\{(P_\ell, u, Q_n, w) \mid u \in R_\ell, w \in R_n \cup \mathcal{R} \}
\cup
\{(t(u), v) \mid t \in \mathcal{R}, u \in R_\ell, v \in R_n \}
\cup
\{(u, |v|) \mid u \in R_\ell, v \in R_n \}
\cup
\{(|t|, |v|) \mid t \in \mathcal{R}, u \in R_\ell, v \in R_n \}
\cup
\{(|t(u)|, v) \mid t \in \mathcal{R}, u \in R_\ell, v \in R_n \}
\cup
\{(u, |v|) \mid u \in R_\ell, v \in R_n \}
\cup
\{(u, |v|) \mid u \in R_\ell, v \in R_n \}
\cup
\{(u, |v|) \mid u \in R_\ell, v \in R_n \}
\cup
\{(u, |v|) \mid u \in R_\ell, v \in R_n \}.
\]

It suffices to show that \(\mathcal{R}\) is an ep-bisimulation. I.e., all entries in \(\mathcal{R}\) satisfy the requirements of Definition 8. We proceed by structural induction.

**Induction base:** Suppose \((P, Q, R) \in \mathcal{R}'\) for some ep-bisimulation \(\mathcal{R}'\). Since \(\mathcal{R}' \subseteq \mathcal{R}\), all requirements of Definition 8 are satisfied.

**Induction step:** Suppose \((P_\ell, Q_\ell, R_\ell), (P_n, Q_n, R_n) \in \mathcal{R}\) satisfy all requirements of Definition 8, we prove that \((P, Q, R)\), where \(P = P_\ell \cdot P_n, Q = Q_\ell \cdot Q_n\) and \(R = R_\ell \cdot R_n\), also satisfies those requirements.

\(R \subseteq en(P) \times en(Q)\) follows from \(R_\ell \subseteq en(P_\ell) \times en(Q_\ell)\) and \(R_n \subseteq en(P_n) \times en(Q_n)\).

**Requirement 1.a:** It suffices to find, for each \(\chi \in en(P)\), \(\zeta \in en(Q)\) with \(\chi \parallel R \zeta\).

1. Suppose \(\chi = t |P_\ell\) for some \(t \in en(P_\ell)\) with \(t \parallel R \zeta\).
   - We obtain \(v \in R_\ell\) and pick \(\zeta = v |Q_\ell\).
2. Suppose \(\chi = P_\ell |u\) for some \(u \in en(P_\ell)\) with \(u \parallel R \zeta\).
   - We obtain \(w \in R_n\) and pick \(\zeta = Q_n |u\).
3. Suppose \(\chi = v |P_\ell\) for some \(v \in en(Q_\ell)\) with \(v \parallel R \zeta\).
   - We obtain \(w \in en(Q_n)\) and \(w \parallel R \zeta\).
4. Suppose \(\chi = v |u|\) for some \(v \in en(Q_\ell)\) and \(u \in en(P_n)\) with \(v \parallel R \zeta\).
   - We obtain \(w \in en(Q_n)\) and \(w \parallel R \zeta\).

In all cases, \(\zeta \in en(Q)\) and \(\chi \parallel R \zeta\) hold trivially.

**Requirement 1.b:** The proof is similar to that of Requirement 1.a and is omitted.

**Requirement 1.c:** This follows directly from the observation that

- \(\ell(t) = \ell(v) \implies \ell(t |P_\ell) = \ell(v |Q_\ell)\),
- \(\ell(u) = \ell(w) \implies \ell(P_\ell |u) = \ell(Q_n |w)\), and
- \(\ell(t) = \ell(u) \implies \ell(v) = \ell(w)\),

provided that the composed transitions exist.

**Requirement 2:** It suffices to find, for arbitrary \(\Upsilon, \Upsilon'\) with \(\Upsilon \parallel R \Upsilon'\), an \(\Upsilon'\) with \((target(\Upsilon), target(\Upsilon'), \Upsilon') \in \mathcal{R}\), such that

(a) for arbitrary \(\chi, \chi'\) with \(\chi \parallel R \chi'\) and \(\Upsilon \parallel R \Upsilon'\), \(\zeta\) can find a \(\zeta'\) with \(\chi' \parallel R \zeta'\) and \(\zeta \parallel R \zeta'\),

(b) for arbitrary \(\chi, \chi'\) with \(\chi \parallel R \chi'\) and \(\Upsilon \parallel R \Upsilon'\), \(\zeta'\) can find a \(\zeta\) with \(\chi \parallel R \zeta\) and \(\zeta \parallel R \zeta'\).

Below we focus merely on (a), as (b) will follow by symmetry.

1. Suppose \(\Upsilon = v |P_\ell\) and \(\Upsilon' = v' |Q_n\) with \(v \parallel v'\). We obtain \(R'_\ell\) that satisfies Requirement 2 with respect to \(v \parallel v'\). Pick \(R' = R'_\ell |R_n\). Then \((target(\Upsilon), target(\Upsilon'), \Upsilon') = (target(v) |P_\ell, target(v') |Q_n, R'_\ell |R_n) \in \mathcal{R}\).

- a. Suppose \(\chi = t |P_\ell\) and \(\chi' = t' |Q_n\) with \(t \parallel R \zeta\). From \(\chi \parallel R \zeta\) we have \(\zeta = x |P_\ell\) for some \(x \parallel R \zeta\). Then we obtain \(x' \parallel R' \zeta'\) and \(x \parallel R' \zeta'.\)

- b. Suppose \(\chi = P_\ell |u\) and \(\chi' = Q_n |u'\) with \(u \parallel u'\). From \(\chi \parallel R \zeta\) we have \(\zeta = target(v) |u\). Pick \(\zeta' = target(v') |u'\). Then \(\chi' \parallel R' \zeta'\) follows directly; \(\zeta' \parallel R' \zeta'\) is given by \(u \parallel u'\).
c. Suppose \( \chi = t|u \) and \( \chi' = t'|u' \) with \( t \sim_v u \) and \( u \sim R \ u' \). From \( \chi \sim_T \zeta \) we have \( \zeta = x|u \) for some \( x \) with \( t \sim_v x \). Then we obtain \( x' \) with \( t' \sim_v x' \) and \( x \sim R \ x' \). Pick \( \zeta' = x'|u' \). Then \( \chi' \sim_T \zeta' \) follows from \( t' \sim_v x' \); \( \zeta \sim R' \zeta' \) is given by \( x \sim R' \ x' \) and \( u \sim R' \ u' \).

2. Suppose \( Y = P\wedge w \) and \( Y' = Q\wedge w' \) with \( w \sim R \ w' \). The proof is similar to that of the previous case.

3. Suppose \( Y = v|w \) and \( Y' = v'|w' \) with \( v \sim R \ v' \) and \( w \sim R \ w' \). We obtain \( R' \) that satisfies Requirement 2 with respect to \( v \) and \( v' \), and \( R'' \) that satisfies Requirement 2 with respect to \( w \) and \( w' \). Pick \( R'' = R''_1 | R''_2 \). Then \( (\text{target}(Y), \text{target}(Y'), R') = (\text{target}(v)|\text{target}(w), \text{target}(v')|\text{target}(w'), R''_1 | R''_2) \in \mathcal{R} \).

a. Suppose \( \chi = t|P \) and \( \chi' = t'|Q \) with \( t \sim v \) and \( t' \sim v' \). From \( \chi \sim_T \zeta \) we have \( \zeta = x|\text{target}(w) \) for some \( x \) with \( t \sim_v x \). Then we obtain \( x' \) with \( t' \sim_v x' \) and \( x \sim R \ x' \). Pick \( \zeta' = x'|\text{target}(w') \). Then \( \chi' \sim_T \zeta' \) follows from \( t' \sim_v x' \); \( \zeta' \sim R'' \zeta' \) is given by \( x \sim R'' \ x' \).

b. Suppose \( \chi = P|u \) and \( \chi' = Q|w' \) with \( u \sim R \ u' \). From \( \chi \sim_T \zeta \) we have \( \zeta = \text{target}(v)|y \) for some \( y \) with \( u \sim w \ y \). Then we obtain \( y' \) with \( u'|\sim w \ y' \) and \( y \sim R'' \ y' \). Pick \( \zeta' = \text{target}(v')|y' \). Then \( \chi' \sim_T \zeta' \) follows from \( t' \sim_v x' \); \( \zeta' \sim R'' \zeta' \) is given by \( x \sim R'' \ x' \).

c. Suppose \( \chi = t|u \) and \( \chi' = t'|u' \) with \( t \sim R \ t' \) and \( u \sim R \ u' \). From \( \chi \sim_T \zeta \) we have \( \zeta = x|y \) for some \( x \) with \( t \sim_v x \) and \( u \sim w \ y \). Then we obtain \( x', y' \) with \( t' \sim v \ x' \), \( u'|\sim w \ y' \), \( x \sim R'' \ x' \), and \( y \sim R'' \ y' \). Pick \( \zeta' = x'|y' \). Then \( \chi' \sim_T \zeta' \) follows from \( t' \sim_v x' \) and \( u'|\sim w \ y' \); \( \zeta' \sim R'' \zeta' \) is given by \( x \sim R'' \ x' \) and \( y \sim R'' \ y' \).

\( \blacktriangleleft \)
B Synchrons – an Alternative Interpretation of ABCdE as an LTSS

In [9], each transition is seen as the synchronisation of a number of so-called synchrons. Each synchron of a transition \( t \in T_r \) represents a path in the proof tree \( t \) from its root to a leaf. If \( \text{source}(t) = P \in \mathbb{P} \) a synchron of \( t \) is also a synchron of \( P \), and can be seen as a path in the parse tree of \( P \) to an unguarded subexpression \( 0, \alpha.Q \) or \( Q \)'s of \( P \) – except that recursion \( A \overset{\text{def}}{=} P \) gets unfolded in the construction of such a path. Here a subexpression of \( P \) occurs unguarded if it does not lay within a subexpression \( \beta.O \) of \( P \).

Definition 29 (Synchrons [9]). Let the set \( \text{Arg} \) of arguments be \( \{ +, \cdot, +_n, |, \text{in}, \text{L}, [f], A, \cdot, \text{r} | L \subseteq \mathcal{C} \cup \mathcal{I} \cup f \} \). A synchron is an expression \( \sigma(S_P) \), \( \sigma(b) \) or \( \sigma(P^{*\ast}) \) with \( \sigma \in \text{Arg}^* \), \( \alpha \in \text{Act}, b \in \mathcal{B}, s \in \mathcal{I} \) and \( P \in \mathbb{P} \). An arguments \( t \in \text{Arg} \) is applied componentwise to a set \( \Sigma \) of synchrons: \( \iota(\Sigma) := \{ \varsigma | \varsigma \in \Sigma \} \). The set \( \varsigma(P) \) of synchrons of an ABCdE process \( P \) is inductively defined by

\[
\varsigma(0) = \{ (b) | b \in \mathcal{B} \} \quad \varsigma(a.P) = \{ (\varsigma_t P) \} \cup \{ (b) | b \in \mathcal{B} \} \quad \varsigma(b.a.P) = \{ (b) \}
\]

\[
\varsigma(P+Q) = +\varsigma(P) \cup +\varsigma(Q) \quad \varsigma(P|Q) = |\varsigma(P) \cup |\varsigma(Q)
\]

\[
\varsigma(P|L) = \{ L\varsigma(L) \} \quad \varsigma(P[f]) = [f]\varsigma(P)
\]

\[
\varsigma(A) = A\varsigma(P) \quad \varsigma(P^{*\ast}) = \{ (P^{*\ast}) \} \cup \varsigma(P).
\]

The set \( \varsigma(t) \) of synchrons of a transition \( t \) is inductively defined by

\[
\varsigma(b.0) = \{ (b) \} \quad \varsigma(b.a.P) = \{ (b) \}
\]

\[
\varsigma(t+Q) = +\varsigma(t) \cup +\varsigma(Q) \quad \varsigma(t|u) = +\varsigma(t) \cup +\varsigma(u)
\]

\[
\varsigma(t|L) = |\varsigma(t) \cup |\varsigma(L) \quad \varsigma(t[f]) = [f]\varsigma(t)
\]

\[
\varsigma(P^{*\ast}) = \{ (P^{*\ast}) \} \quad \varsigma(t.r) = \cdot r \varsigma(t).
\]

Note that we use the symbol \( \varsigma \) as a variable ranging over synchrons, and as the name of two functions – disambiguated by context. Also \( v, \nu \) and \( \xi \) will range over synchrons. Here \( v \) – the Greek letter \( \upsilon \) – should not be confused with the Latin letter \( v \), denoting a transition.

Lemma 30 ([9]). If \( t \in T_r \) and \( P = \text{source}(t) \) then \( \varsigma(t) \subseteq \varsigma(P) \).

Proof. A structural induction on \( t \).

Lemma 31. A transition \( t \) is uniquely identified by \( \text{source}(t) \) and \( \varsigma(t) \).

Proof. We support this lemma with a partial function \( \text{retrieve} \) to retrieve the transition from its source and set of synchrons – provided that the corresponding transition exists.

\[
\text{retrieve}(P, \Sigma) \quad \text{where} \quad P \in \mathbb{P} \text{ and } \Sigma \subseteq \varsigma(P) \text{ is inductively defined by}
\]

\[
\text{retrieve}(0), \{ (b) \} = b.0
\]

\[
\text{retrieve}(\alpha.P), \{ (\varsigma_t P) \} = \alpha P
\]

\[
\text{retrieve}(\alpha.P), \{ (b) \} = b.a.P
\]

\[
\text{retrieve}(P + Q), +\varsigma(P_\Lambda) = \text{retrieve}(P, \Sigma_\Lambda) + Q
\]

\[
\text{retrieve}(P + Q), +\varsigma(P_\Lambda) = P + \text{retrieve}(Q, \Sigma_\Lambda)
\]

\[
\text{retrieve}(P|Q), |\varsigma(P_\Lambda) = \text{retrieve}(P, \Sigma_\Lambda)|Q
\]

\[
\text{retrieve}(P|Q), |\varsigma(P_\Lambda) = P|\text{retrieve}(Q, \Sigma_\Lambda)
\]

\[
\text{retrieve}(P|\Lambda), |\varsigma(P_\Lambda) = \text{retrieve}(P, \Sigma_\Lambda)|\text{retrieve}(Q, \Sigma_\Lambda) \quad \text{when } \Sigma_\Lambda, \Sigma_\Lambda \neq \emptyset
\]

\[
\text{retrieve}(P|\Lambda), |\varsigma(P_\Lambda) = \text{retrieve}(P, \Sigma_\Lambda)|\text{retrieve}(Q, \Sigma_\Lambda) \quad \text{when } \Sigma_\Lambda, \Sigma_\Lambda \neq \emptyset
\]

\[
\text{retrieve}(P|\Lambda), L\varsigma(L) = \text{retrieve}(P, \Sigma_\Lambda)|L
\]

\[
\text{retrieve}(P|f), [f]\Sigma_\Lambda = \text{retrieve}(P, \Sigma_\Lambda)|f
\]

\[
\text{retrieve}(A), A\varsigma(P) = A: \text{retrieve}(P, \Sigma)
\]

\[
\text{retrieve}(P^{*\ast}), \{ (P^{*\ast}) \} = P^{*\ast}
\]

\[
\text{retrieve}(P^{*\ast}), \cdot r \Sigma = \text{retrieve}(P, \Sigma)\cdot r
\]

\[
\text{retrieve}(P^{*\ast}), \{ (P^{*\ast}) \} = P^{*\ast}
\]
B.1 Concurrency Relations between Synchrons and Transitions

▶ Definition 32 (Active and Necessary Synchrons). All synchrons of the form \( \sigma(P) \) are active; synchrons \( \sigma(P) \) and \( \sigma(b) \) are passive. Moreover, all synchrons that are not of the form \( \sigma(P) \) or \( \sigma(b) \) are necessary. Let \( a(t) \) denote the set of active synchrons of the transition \( t \), and \( n(t) \) its set of necessary synchrons.

Intuitively, the execution of an active synchron \( \sigma(P) \) causes a transition \( \alpha.P \xrightarrow{\sigma} P \) in the relevant component of the represented system, whereas the execution of a passive synchron does not cause any state change. Moreover, since for any \( b \in B \) a transition labelled \( b \) or \( b \) is enabled by any ABCdE process in any state, whether a broadcast action \( b \) can take place depends only on the presence of a \( b \)-synchron; its synchronisation partners of the form \( \sigma(P) \) or \( \sigma(b) \) are not necessary for a \( b \)-transition to occur. In this paper we choose to see a transition labelled \( b \) or \( b \) merely as the potential for receiving or discarding a broadcast \( b \); none of the synchrons of such a transition is necessary.

▶ Definition 33 (Concurrency [9]). Two synchrons \( \varsigma \) and \( \upsilon \) are concurrent, notation \( \varsigma \sim_d \upsilon \), if \( \varsigma = \sigma|_0 \varsigma' \) and \( \upsilon = \sigma|_u \upsilon' \) with \( \sigma \in Arg^r \), \( \{D, E\} = \{L, R\} \), and \( \varsigma', \upsilon' \) synchrons.

A synchron \( \varsigma \) is unaffected by a transition \( u \), notation \( \varsigma \sim_d u \), if \( \forall \upsilon \in a_\varsigma(u). \varsigma \sim_d \upsilon \).

A transition \( t \) is unaffected by a transition \( u \), iff \( \text{source}(t) = \text{source}(u) \) and \( \forall \varsigma \in a_\varsigma(t). \varsigma \sim_d u \).

▶ Example 34. Let \( P = (bl.0)^s | (s.0 + b?0) \in P \), \( t = (bl.0)^s | (s.0 + (b?0)) \in Tr \) and \( u = (bl.0)^s | ((s?0) + b?0) \in Tr \). Then \( t \equiv t, t(u) = \tau, \text{source}(t) = \text{source}(u) = P, \) \( \text{target}(t) = 0 \) and \( \text{target}(u) = (bl.0)^s | 0 \). Transition \( t \) has exactly two synchrons, namely \( \varsigma := |_n s_*(bl.0)^s, \) and \( \upsilon := |_n s_*(b?0) \). Also \( u \) has two synchrons, namely \( \nu := |_n (bl.0)^s \) and \( \xi := |_n (s?0) \). Of these synchrons, \( \varsigma, \upsilon \) and \( \xi \) are active, whereas \( \varsigma, \nu \) and \( \xi \) are necessary.

We have \( \varsigma \sim_d \upsilon \), since these two synchrons stem from opposite sides of a parallel composition. Likewise \( \varsigma \sim_d \xi, \upsilon \sim_d \nu \) and \( \nu \sim_d \xi \), yet \( \varsigma \not\sim_d \nu \) and \( \nu \not\sim_d \xi \).

Transition \( u \) is affected by \( t \), \( t \not\sim_d u \), since its necessary synchron \( \nu \) is affected by \( t \). I.e., \( \nu \not\sim_d t \). This is because \( \varsigma \) is an active synchron of \( t \). This verdict is consistent with the observation that after doing \( t \) it is no longer possible to perform a \( \tau \)-action.

Yet \( t \not\sim_d u \). I.e., \( t \) is not affected by \( u \). Namely \( \varsigma \), the only necessary synchron of \( t \), is not affected by \( u \); i.e., \( \varsigma \sim_d u \). This holds because \( \varsigma \sim_d \xi \). The fact that \( \varsigma \sim_d \nu \) does not stand in the way of \( \varsigma \sim_d u \), because the synchron \( \nu \) is not active. The fact that \( \nu \sim_d \xi \) and hence \( \nu \not\sim_d u \) does not stand in the way of \( t \sim_d u \), because the synchron \( \nu \) is not necessary. This verdict is consistent with the observation that after doing \( u \) it is still possible to perform a \( b \)-action.

Let \( Tr^{\tau} \subseteq Tr \) be the set of transitions \( t \) with \( \ell(t) \notin B \) or \( B \); in [9], a concurrency relation \( \sim \subseteq Tr^{\tau} \times Tr \) that also relates transitions that do not share the same source, was defined. Restricted to pairs of transitions that do share the same source it coincides with the relation \( \sim' \) of Definition 33, as was remarked in [9, Section 11]. In [9] the relation \( \sim_d \) between synchrons was called direct concurrency, which explains the subscript \( d \). There it was used to define a more liberal relation \( \sim \) between synchronous components, which in turn was used to define the relation \( \sim \subseteq Tr^{\tau} \times Tr \). Since in this paper we study concurrency relations merely between transitions that share the same source, we may use \( \sim_d \) instead of \( \sim \).

Later on, we will show that the relation \( \sim' \) coincides with the relation \( \sim \) from the present paper, which is derived from Definition 20.
B.2 Classifying the Sets of Synchrons of Transitions

Define the label of a synchron by $\ell(\sigma(\delta P)) = a$, $\ell(\sigma(b)) = b$ and $\ell(\sigma(P^{\rightarrow*})) = \bar{s}$.

Lemma 35. Let $t \in Tr$.

- Either $t$ has exactly one synchron $\varsigma$, with $\ell(\varsigma) = \ell(t) \in G \cup \hat{G} \cup \{\tau\} \cup F \cup \hat{F}$, 
- or $\varsigma(t) = \{\varsigma, v\}$, with $\ell(\varsigma) \in G \cup \hat{G} \cup F \cup \hat{F}$, $\ell(v) = \ell(\varsigma)$, $\varsigma \prec_d v$ and $\ell(t) = \tau$,
- or $\varsigma(t) \neq \emptyset$, there is a $b \in \mathcal{B}$ such that $\ell(\varsigma) \in \{b!, b?, b\}$ for all $\varsigma \in \varsigma(t)$, and
  - $\ell(t) = b!$ and $\ell(\varsigma) = b!$ for exactly one $\varsigma \in \varsigma(t)$, or
  - $\ell(t) = b?$ and $b? \in \{\ell(\varsigma) \mid \varsigma \in \varsigma(t)\} \subseteq \{b?, b\}$, or
  - $\ell(t) = b$ and $\ell(\varsigma) = b$ for all $\varsigma \in \varsigma(t)$.

Proof. A trivial induction on the definition of $\varsigma(t)$.

The next result classifies exactly which sets of synchrons $\Sigma \subseteq \varsigma(P)$ arise as $\Sigma = \varsigma(t)$ for some transition $t \in en(P)$.

Definition 36. A set of synchrons $\Sigma \subseteq \varsigma(P)$ is P-complete if

1. either $\Sigma = \{\varsigma\}$ with $\ell(\varsigma) \in G \cup \hat{G} \cup \{\tau\} \cup F \cup \hat{F}$,
2. or $\Sigma = \{\varsigma, v\}$, with $\ell(\varsigma) \in G \cup \hat{G} \cup F \cup \hat{F}$, $\ell(v) = \ell(\varsigma)$, and $\varsigma \prec_d v$,
3. or there is a $b \in \mathcal{B}$ such that
   - $\ell(\varsigma) \in \{b!, b?, b\}$ for all $\varsigma \in \Sigma$,
   - $\ell(\varsigma) = b!$ for at most one $\varsigma \in \Sigma$,
   - $\varsigma \prec_d v$ for each pair $\varsigma, v \in \Sigma$ with $\varsigma \neq v$ and either $\ell(\varsigma) \neq b$ or $\ell(v) \neq b$,
   - if $\varsigma \in \varsigma(P)$ with $\ell(\varsigma) = b!$ and $\varsigma \prec_d v$ for each active synchron $v \in \Sigma \setminus \{\varsigma\}$, then $\varsigma \in \Sigma$, and
   - if $\varsigma \in \varsigma(P)$ with $\ell(\varsigma) = b$ and $\varsigma \prec_d v$ for each active synchron $v \in \Sigma$, then $\varsigma \in \Sigma$.

Theorem 37. A set of synchrons $\Sigma \subseteq \varsigma(P)$ is P-complete iff $\varsigma(t) = \Sigma$ for some $t \in en(P)$.

Proof. ‘If’ follows by a straightforward induction on the definition of $\varsigma(t)$, using Lemma 35.

For ‘only if’, the first case of Definition 36 follows by structural induction on $\varsigma$. Using this, the second case of Definition 36 follows by structural induction on the common prefix $\sigma$ of the two synchrons in $\Sigma$. The third case of Definition 36 proceeds by induction on the well-founded order $<$ on sets $\Sigma$ of synchrons, defined by $\Sigma' < \Sigma$ iff $\Sigma'$ is a proper subset of $\Sigma$ for some $t \in \text{Arg}$. All steps are straightforward.

B.3 From Source to Target

We now explore how the sets of synchrons of processes evolve with transitions - i.e., how $\varsigma(P)$ becomes $\varsigma(Q)$ when a transition $w$ with $\text{source}(w) = P$ and $\text{target}(w) = Q$ is taken.

If a process $P$ has a synchron $\varsigma$ that is not affected by a transition $w \in en(P)$, then after executing $w$ a variant of $\varsigma$ ought to remain a synchron of the target state $\text{target}(w)$. We will denote this variant as $\varsigma@w$.

Example 38. Let $P = (a.0|d.0)+c.0$, $\varsigma = +_{\text{en}}(\frac{d}{\rightarrow 0}) \in \varsigma(P)$ and $w = ((\frac{a}{\rightarrow 0})|d.0)+c.0 \in en(P)$. Then $\varsigma \prec_d w$ and $\varsigma@w = |_{\text{en}}(\frac{d}{\rightarrow 0}) \in \text{en}(Q)$, where $Q = \text{target}(w) = 0.d.0$.

Definition 39 (Dynamic and Static Arguments [9]). The arguments $+_{l}, +_{r}, A$ and $\tau$ are called dynamic; the others are static. For $\sigma \in \text{Arg}^*$, let $\text{static}(\sigma)$ be the result of removing all dynamic arguments from $\sigma$. Moreover, for $\varsigma = \sigma v$ with $v \in \{(\frac{a}{\rightarrow} P), (P^{\rightarrow*}), (b);\}$, define $\text{static}(\varsigma) := \text{static}(\sigma)v$. 
Definition 40 (After Function [9]). Let $\zeta, \nu$ be synchrons with $\zeta \sim_d \nu$, i.e., $\zeta = \sigma|_\nu \nu'$ and $\nu = \sigma|_\nu \nu'$ with $\sigma \in \text{Arg}^*$, $\{D, E\} = \{L, R\}$, and $\nu', \nu'$ synchrons. Define $\zeta \otimes \nu$, where $\otimes$ is pronounced ‘after’, to be $\text{static}(\sigma)|_\nu \nu'$.

For $w \in Tr$ with $\ell(w) \in \text{Act}$ and $\zeta \not\sim_d w$, i.e., $\forall \nu \in a\zeta(w)$. $\zeta \not\sim_d \nu$, let $\zeta \otimes w := \zeta \otimes \nu$ for the $\nu \in a\zeta(w)$ that is ‘closest’ to $\zeta$, in the sense that it has the largest prefix in common with $\zeta$. Note that $\ell(w) \in \text{Act}$ implies $a\zeta(w) \neq \emptyset$.

For $w \in Tr$ with $\ell(w) \in \mathcal{B} \cup \mathcal{F}$, let $\zeta \otimes w := \zeta$. In this case, $\zeta \not\sim_d w$ trivially holds.

For a set $\Sigma$ of synchrons, define $\Sigma \otimes w := \{\zeta \otimes w \mid \zeta \in \Sigma \land \zeta \not\sim_d w\}$.

The next lemma says that the concurrency relation between synchrons is not affected by the execution of a concurrent transition.

Lemma 41. Let $w \in Tr$ and $\zeta, \nu$ be synchrons with $\zeta \not\sim_d \nu$. Then $\zeta \not\sim_d \nu \Leftrightarrow \zeta \otimes w \not\sim_d \nu \otimes w$.

Proof. The case $\ell(w) \in \mathcal{B} \cup \mathcal{F}$ is trivial, so suppose $\ell(w) \in \text{Act}$. We obtain $\nu \in a\zeta(w)$ that is ‘closest’ to $\zeta$ and $\xi \in a\zeta(w)$ that is ‘closest’ to $\nu$. Then $\zeta \otimes w = \zeta \otimes \nu$ and $\nu \otimes w \not\sim_d \nu \otimes \xi$.

Suppose $\nu = \xi$.

If the common prefix shared by $\zeta$ and $\nu$ is the same as that shared by $\nu$ and $\nu$, then $\zeta = \sigma|_\nu \nu'$ and $\nu = \sigma|_\nu \nu'$ with $\sigma \in \text{Arg}^*$, $\{D, E\} = \{L, R\}$, and $\nu', \nu'$ synchrons. Thus $\zeta \otimes w = \text{static}(\sigma)|_\nu \nu'$ and $\nu \otimes w = \text{static}(\sigma)|_\nu \nu'$. Hence $\zeta \not\sim_d \nu \Leftrightarrow \zeta \not\sim_d \nu' \Leftrightarrow \zeta \otimes w \not\sim_d \nu \otimes w$.

If the common prefix shared by $\zeta$ and $\nu$ is shorter than that shared by $\nu$ and $\nu$, then $\zeta = \sigma|_\nu \nu'$ and $\nu = \sigma|_\nu \nu'$ with $\sigma \in \text{Arg}^*$, $\{D, E\} = \{L, R\}$, and $\nu', \nu'$ synchrons. Hence $\zeta \not\sim_d \nu$ and $\zeta \otimes w \not\sim_d \nu \otimes w$ always hold.

If the common prefix shared by $\zeta$ and $\nu$ is longer than that shared by $\nu$ and $\nu$, the proof is similar to that of the previous case.

Suppose $\nu \neq \xi$ and the first argument where $\nu$ and $\xi$ differ is a $+_L$ versus $+_R$. We have $\nu = \sigma|_\nu \nu'$ and $\xi = \sigma|_\nu \xi'$ with $\sigma \in \text{Arg}^*$, $\{D, E\} = \{L, R\}$, and $\nu', \xi'$ synchrons.

If either the common prefix shared by $\zeta$ and $\nu$ or that shared by $\zeta$ and $\xi$ is shorter than $\sigma$, then the proof is similar to that for the case where $\nu = \xi$. Alternatively, in this case we could have chosen $\nu = \xi$, thereby reducing this case to the previous one.

Otherwise, $\zeta$ has a prefix $\sigma|_\nu$ and $\nu$ has a prefix $\sigma|_R$. Then $\zeta \not\sim_d \xi$ and $\nu \not\sim_d \nu$, contradicting the assumptions $\zeta \not\sim_d w$ and $\nu \not\sim_d w$.

Suppose $\nu \neq \xi$ and the first argument where $\nu$ and $\xi$ differ is a $|_L$ versus $|_R$. We have $\nu = \sigma|_\nu \nu'$ and $\xi = \sigma|_\nu \xi'$ with $\sigma \in \text{Arg}^*$, $\{D, E\} = \{L, R\}$, and $\nu', \xi'$ synchrons.

Again, if either the common prefix shared by $\zeta$ and $\nu$ or that shared by $\zeta$ and $\xi$ is shorter than $\sigma$, then the proof is similar to that for the case where $\nu = \xi$.

Otherwise, $\zeta$ has a prefix $\sigma|_L$, $\nu$ has a prefix $\sigma|_R$, $\zeta \otimes w$ has a prefix $\text{static}(\sigma)|_L$, and $\nu \otimes w$ has a prefix $\text{static}(\sigma)|_R$. Hence $\zeta \not\sim_d \nu$ and $\zeta \otimes w \not\sim_d \nu \otimes w$ always hold.

The following lemma says that, for $w \in Tr$, the operation $\otimes w$ on synchrons of the same process $P$ is injective.

Lemma 42. If $\zeta, \nu \in \mathcal{P}(P)$ with $\zeta \neq \nu$ and $\zeta \not\sim_d w$, $\nu \not\sim_d w$ for some $w \in Tr$, then $\zeta \otimes w \neq \nu \otimes w$.

Proof. If $\ell(w) \in \mathcal{B} \cup \mathcal{F}$ then $\zeta \otimes w = \zeta \neq \nu = \nu \otimes w$. If $\ell(w) \in \text{Act}$, then let $\nu \in a\zeta(w)$ be the synchron ‘closest’ to $\zeta$, and $\xi \in a\zeta(w)$ be the one ‘closest’ to $\nu$, so that $\zeta \otimes w = \zeta \otimes \nu$ and $\nu \otimes w = \nu \otimes \xi$. Suppose $\zeta \otimes w = \nu \otimes w$. Since $\zeta$ and $\nu$ are synchrons of the same process, the first argument where they differ must be either (a) a $+_L$ versus $+_R$, or (b) a $|_L$ versus $|_R$. $\zeta$ and $\nu$ cannot become the same after the $\otimes w$ operation in the case of (b), because $\otimes w$ can
We conclude this section with an algorithm to calculate the set of synchrons of a state.

Thus we obtain $\xi \vdash \nu$ for some active synchron $\nu$. Hence $\nu \nRightarrow w \in a\xi(w)$, contradicting the assumption $v \sim_d w$. Thus $\xi w \neq v\circ w$.

The synchrons affected by a transition are ‘destroyed’ after that transition is taken. At the same time, some new synchrons are introduced. We denotes the set of new synchrons introduced by taking $w \in Tr$ as new($w$).

**Example 43.** Let $P = \alpha.Q$ and $w = (\leq_0 Q) \in en(P)$. Taking the transition $w$ ‘activates’ the active synchron $(\leq_0 Q)$, which removes the ‘guard’ $\alpha$ and ‘reveals’ the synchrons in $Q$. Then new($w$) = $\iota(Q) \subseteq \iota(target(w))$.

**Definition 44 (New Function).** Let $v$ be an active synchron. I.e., $v = \sigma(\leq_0 P)$ for some $\sigma \in Arg^*$, $\alpha \in Act$ and $P \in P$. Define new($v$) := { static($\sigma$)$_\ell$ | $\ell \in \iota(P)$ }.

For $w \in Tr$, let new($w$) := \bigcup\{new($v$) | $v \in a\xi(w)$\}.

**Lemma 45.** Let $\nu, \xi$ be two active synchrons, $\zeta \in new(\nu)$ and $v \in new(\xi)$. If $\nu \sim_d \xi$ then $\zeta \sim_d \nu$.

Proof. From $\nu \sim_d \xi$, we have $\nu = \sigma|_{\nu} \nu'$ and $\xi = \sigma|_{\xi} \xi'$ with $\sigma \in Arg^*$, $\{D, E\} = \{L, R\}$, and $\nu', \xi'$ synchrons. By Definition 44, $\zeta$ has a prefix static($\sigma$)$_{\nu'}$ and $v$ has a prefix static($\sigma$)$_{\xi'}$. Thus $\zeta \sim_d \nu$.

The opposite direction of Lemma 45 does not hold.

**Example 46.** Let $\nu = \xi = (\leq_0 (c.0 | d.0))$, $\zeta = |_{\nu}(\leq_0 0)$ and $v = |_{\nu}(\leq_0 0)$. Then $\nu, \xi$ are active synchrons, $\zeta \in new(\nu)$, $v \in new(\xi)$ and $\nu \sim_d \xi$. However, $\nu \nRightarrow \xi$.

The next result says that the inherited synchrons after a transition are always concurrent with the new ones.

**Lemma 47.** Let $w \in en(P)$. If $\zeta \in new(w)$ and $v \in \zeta(P)w$ then $\zeta \sim_d \nu$.

Proof. From $\zeta \in new(w)$ we obtain $v \in a\xi(w)$ such that $\zeta \in new(\nu)$. From $v \in \zeta(P)w$ we obtain $\xi \in \zeta(P)$ with $\nu \sim_d w$ such that $v = \xi\circ w$. From $\nu \sim_d w$ we have $\nu \sim_d \nu$. Thus $\nu = \sigma|_{\nu} \nu'$ and $\xi = \sigma|_{\xi} \xi'$ with $\sigma \in Arg^*$, $\{D, E\} = \{L, R\}$, and $\nu', \xi'$ synchrons. From $\zeta \in new(\nu)$ we have $\zeta = static(\sigma)|_{\nu} \nu'$ for some synchron $\nu'$. From $v = \xi\circ w$ and the fact that $\nu$ shares the prefix $\sigma$ with $\xi$, we have $v = static(\sigma)|_{\nu} \nu'$ for some synchron $\nu'$. Thus $\zeta \sim_d \nu$.

**Corollary 48.** Let $w \in en(P)$. $\zeta(P)w$ and new($w$) are disjoint.

Proof. This follows from Lemma 47 and the fact that $\sim_d$ is irreflexive.

We conclude this section with an algorithm to calculate the set of synchrons of a state $Q$ reached after a doing a transition $w \in enP$ as a function of $w$ and the set of synchrons of $P$.

**Theorem 49.** If $w \in Tr$, $P = source(w)$ and $Q = target(w)$ then $\zeta(Q) = \zeta(P)w \cup new(w)$.

Proof. First suppose $\ell(w) \in \mathcal{R} \cup \mathcal{F}$. Then $a\xi(w) = \emptyset$ and $Q = P$. We have $\zeta(P)w = \zeta(P)$ and new($w$) = $\emptyset$. Hence $\zeta(Q) = \zeta(P) = \zeta(P)w \cup new(w)$.

Now suppose $\ell(w) \in Act$. We proceed by structural induction on $\zeta(w)$, using the same well-founded order $<$ on sets of synchrons as in the proof of Theorem 37.
Enabling Preserving Bisimulation Equivalence

**Induction base:** Suppose \( \varsigma(w) = \{ (\Sigma Q') \} \) for some \( \alpha \in \mathit{Act} \) and \( Q' \in \mathbb{P} \). Then \( P = \alpha.Q' \) and \( Q = Q' \). We have \( \varsigma(P)@w = \emptyset \) and \( \mathit{new}(w) = \varsigma(Q') \). Hence \( \varsigma(Q) = \varsigma(Q') = \varsigma(P)@w \cup \mathit{new}(w) \).

**Induction step:** Given \( w \in \mathit{Tr} \), \( P = \mathit{source}(w) \) and \( Q = \mathit{target}(w) \), we assume that \( \varsigma(Q') = \varsigma(P')@w' \cup \mathit{new}(w') \) for all \( w' \in \mathit{Tr} \), \( P' = \mathit{source}(w') \) and \( Q' = \mathit{target}(w') \) such that \( \varsigma(w') < \varsigma(w) \).

Suppose \( \varsigma(w) = \Sigma_{\varsigma}n_{\varsigma} \) for some \( \Sigma_{\varsigma} \). Then \( P = P_{n}P_{n} \) and \( w = w_{n}P_{n} \) for some \( P_{n}, P_{n} \in \mathbb{P} \) and \( w_{n} \in \mathit{en}(P_{n}) \) with \( \varsigma(w_{n}) = \Sigma_{\varsigma}n_{\varsigma} \). Thus \( Q = Q_{n}Q_{n} \) for some \( Q_{n}, Q_{n} \in \mathbb{P} \) with \( Q_{n} = \mathit{target}(w_{n}) \). Using that \( +_{\varsigma}n_{\varsigma} \cup +_{\varsigma}v = \varsigma(v) \) whenever \( \varsigma \sim w \), we have \( \varsigma(P)@w = \varsigma(P)@w_{n} \cup \mathit{new}(w_{n}) \). By (IH), \( \varsigma(Q_{n}) = \varsigma(P)@w_{n} \cup \mathit{new}(w_{n}) \). Hence \( \varsigma(Q) = \varsigma(Q_{n}) \cup \mathit{new}(w_{n}) \).

Suppose \( \varsigma(w) = \Sigma_{\varsigma}n_{\varsigma} \) for some \( \Sigma_{\varsigma} \). The proof is similar to that of the previous case.

Suppose \( \varsigma(w) = \Sigma_{\varsigma}n_{\varsigma} \) for some non-empty \( \Sigma_{\varsigma}, \Sigma_{n_{\varsigma}} \). Then \( P = P_{n}P_{n} \) and \( w = w_{n}P_{n} \) for some \( P_{n}, P_{n} \in \mathbb{P} \), \( w_{n} \in \mathit{en}(P_{n}) \) with \( \varsigma(w_{n}) = \Sigma_{\varsigma}n_{\varsigma} \) and \( \mathit{en}(w_{n}) = \Sigma_{n_{\varsigma}} \). Thus \( Q = Q_{n}Q_{n} \) for some \( Q_{n}, Q_{n} \in \mathbb{P} \) with \( Q_{n} = \mathit{target}(w_{n}) \). Using that \( \varsigma@w = \varsigma@w_{n} \cup \mathit{new}(w_{n}) \) and \( \mathit{new}(w) = \mathit{new}(w_{n}) \). By (IH), \( \varsigma(Q_{n}) = \varsigma(P)@w_{n} \cup \mathit{new}(w_{n}) \). Hence \( \varsigma(Q) = \varsigma(Q_{n}) \cup \mathit{new}(w_{n}) \).

Suppose \( \varsigma(w) = \emptyset \) for some \( \emptyset \). The proof is similar to that of the previous case.

Suppose \( \varsigma(w) = A \Sigma_{r} \) for some \( A = A \Sigma_{r} \) and \( \Sigma_{r} \). Then \( P = A \Sigma_{r} \) and \( w = w_{r} \) for some \( P_{r} \in \mathbb{P} \) and \( w_{r} \in \mathit{en}(P_{r}) \) with \( \varsigma(w_{r}) = \Sigma_{r} \). Thus \( Q = Q_{r} \) for some \( Q_{r} \in \mathbb{P} \) with \( Q_{r} = \mathit{target}(w_{r}) \). Using that \( A \Sigma_{r} \cup A \Sigma_{r} = \varsigma(v) \) whenever \( \varsigma \sim w \), we have \( \varsigma(P)@w = \varsigma(P)@w_{r} \cup \mathit{new}(w_{r}) \). Hence \( \varsigma(Q) = \varsigma(Q_{r}) \cup \mathit{new}(w_{r}) \).

Suppose \( \varsigma(w) = \emptyset \) for some \( r \in \mathcal{R} \) and \( \Sigma_{r} \). The proof is similar to that of the previous case.

**B.4 What Happens to a Transition after a Concurrent Transition?**

If a process \( P \) enables a transition \( t \) that is not affected by a transition \( w \in \mathit{en}(P) \), then a variant \( t' \) of \( t \) ought to remain enabled in the state \( \mathit{target}(w) \) reached after executing \( w \). We denote this by \( t \sim_{\mathit{en}(P)} w \). Unlike the situation for synchrons in Section B.3, the transition \( t' \) is not fully determined by \( t \) and \( w \).

**Example 50.** Let \( P = a.(b?.P_{1} + b?.P_{2}) \ | \ b!.0 \), \( t = b.a.(b?.P_{1} + b?.P_{2}) \ | \ (b!.0) \), and let \( w \) be the transition \( (\Sigma (b?.P_{1} + b?.P_{2})) \ | \ b!.0 \). Since the \( b \)-synchron of \( t \) is not necessary, \( t \) is not affected by \( w \), i.e., \( t \sim_{\mathit{en}(P)} w \). So there must be a transition \( t' \) with \( t \sim_{\mathit{en}(P)} w' \). However, the
process \( \text{target}(w) \) enables exactly two \( bl \)-transitions, and they are equally plausible candidates for \( t' \).

The same example applies when leaving out the parallel component \( bl!0 \). In that case \( \ell(t) = b \) and \( \ell(t') = b? \).

\[ \boxed{\text{Definition 51 (Possible Successor Transition).} \quad \text{A transition } t' \text{ is a possible successor of a transition } t \text{ after a transition } w, \text{ notation } t \rightsquigarrow_w t', \text{ iff}} \]

1. \( \text{source}(t) = \text{source}(w) \),
2. \( \text{source}(t') = \text{target}(w) \),
3. \( t \rightsquigarrow_w w \),
4. for all \( \varsigma \in \varsigma(t) \) with \( \varsigma \rightsquigarrow_d w \), one has \( \varsigma \otimes w \in \varsigma(t') \), and
5. \( \ell(t) = \ell(t') \lor \exists b \in \mathcal{B}. \{ \ell(t), \ell(t') \} = \{ b?, b \} \).

The first two conditions are obvious, and the third states that a successor \( t' \) of \( t \) after \( w \) exists only if \( t \) is unaffected by \( w \). The fourth condition requires that all synchrons \( \varsigma \) of \( t \) that are unaffected by \( w \), return in the form \( \varsigma \otimes w \) as a synchron of \( t' \). The last condition states that the label of \( t' \) should be the same as that of \( t \), with the exception of Footnote 5. We would have imposed one more condition, but by the following lemma it is implied.

\[ \boxed{\text{Lemma 52.} \quad \text{If } t \rightsquigarrow_w t' \text{ then } |n\varsigma(t)| = |n\varsigma(t')| \text{ and } \otimes w \text{ is a bijection between the necessary synchrons of } t \text{ and } t' \text{.}} \]

\[ \text{Proof.} \quad \text{By Lemma 42 } |n\varsigma(t)| \leq |n\varsigma(t')| \text{ and } \otimes w \text{ is an injection from } n\varsigma(t) \text{ to } n\varsigma(t') \text{. It remains to show that } |n\varsigma(t)| = |n\varsigma(t')|. \text{ Note that } \ell(\varsigma \otimes w) = \ell(\varsigma) \text{ for all synchrons } \varsigma \text{ with } \varsigma \rightsquigarrow_d w, \text{ and thus for all } \varsigma \in n\varsigma(t). \]

\[ \text{By Lemma 35, either (i) } n\varsigma(t') = \emptyset \text{ and } \ell(t') \in \mathcal{B}? \cup \mathcal{B}?, \text{ or (ii) } n\varsigma(t') = \{ v \} \text{ for a synchron } v \text{ with } \ell(v) = \ell(t') \notin \mathcal{B}? \cup \mathcal{B}?, \text{ or (iii) } |n\varsigma(t')| = 2 \text{ and } \ell(t') = \tau, \text{ yet } \ell(v) \neq \tau \text{ for all } v \in n\varsigma(t'). \text{ A similar classification applies to } n\varsigma(t). \]

\[ \text{In Case (i) } |n\varsigma(t)| = |n\varsigma(t')| \text{ follows from } |n\varsigma(t)| \leq |n\varsigma(t')|, \text{ and we are done.} \]

\[ \text{In Case (ii) } |n\varsigma(t)| < |n\varsigma(t')| \text{ would imply that } n\varsigma(t) = \emptyset \text{ and } \ell(t) \in \mathcal{B}? \cup \mathcal{B}?, \text{ contradicting Requirement 5 of Definition 51.} \]

\[ \text{In Case (iii) } |n\varsigma(t)| < |n\varsigma(t')| \text{ would imply that either } n\varsigma(t) = \emptyset, \text{ leading to a contradiction just as above, or } n\varsigma(t) = \{ \varsigma \} \text{ for some synchron } \varsigma. \text{ In the latter case } \varsigma \otimes w \in n\varsigma(t'), \text{ so } \ell(t) = \ell(\varsigma) = \ell(\varsigma \otimes w) \neq \tau = \ell(t'), \text{ again a contradiction.} \]

The main result of this appendix, delivered in Section B.5, says that the relation \( \rightsquigarrow' \) defined above coincides with the relation \( \rightsquigarrow \) of Definition 20. This justifies the clauses of Definition 20.

The concurrency relation \( \rightsquigarrow \) in Section 2 is defined as the projection of \( \rightsquigarrow \) on its first two arguments. The next theorem says that likewise \( \rightsquigarrow' \) is the projection of \( \rightsquigarrow' \) on its first two arguments. As a result, \( \rightsquigarrow' \rightleftharpoons \rightsquigarrow' \) will imply \( \rightsquigarrow' \rightleftharpoons \rightsquigarrow' \).

\[ \boxed{\text{Theorem 53.} \quad t \rightsquigarrow' w \text{ iff } \exists t'. \ t \rightsquigarrow'_w t'.} \]

\[ \text{Proof.} \quad \text{By Condition 3 of Definition 51, } \exists t'. \ t \rightsquigarrow'_w t' \implies t \rightsquigarrow' w \text{ trivially holds. It remains to prove } t \rightsquigarrow' w \implies \exists t'. \ t \rightsquigarrow'_w t'. \text{ So assume } t \rightsquigarrow' w \text{ and let } P = \text{source}(t) = \text{source}(w). \]

\[ \text{By Theorem 37, the set } \varsigma(t) \text{ of synchrons is } P\text{-complete, so one of the three possibilities listed in Definition 36 applies.} \]

\[ ^5 \text{This allows a broadcast-receive transition to be a possible successor of a broadcast-discard transition, and vice versa, as required for Example 50b.} \]
Enabling Preserving Bisimulation Equivalence

In the first case, \( \varsigma(t) = \kappa_\varsigma(t) = \{ \varsigma \} \) with \( \ell(\varsigma) \in C \cup G \cup \{ \tau \} \cup \mathcal{I} \cup \mathcal{F} \), and \( \varsigma \sim_d v \). By Theorem 49, \( \varsigma \uplus w \in \varsigma(\text{target}(w)) \). Now \( \Sigma := \{ \varsigma \uplus w \} \) is \( P \)-complete by Definition 36, using that \( \ell(\varsigma \uplus w) = \ell(\varsigma) \). So by Theorem 37 there is a transition \( t' \) with \( \text{source}(t') = \text{target}(w) \) and \( \varsigma(t') = \Sigma \). Now \( t \sim_w t' \), as all conditions of Definition 51 are trivially satisfied. In particular, \( \ell(t) = \ell(\varsigma) = \ell(\varsigma \uplus w) = \ell(t') \), by Lemma 35.

In the second case, \( \varsigma(t) = \kappa_\varsigma(t) = \{ \varsigma, v \} \) with \( \ell(\varsigma) \in C \cup G \cup \mathcal{I} \cup \mathcal{F} \), \( \ell(v) = \overline{\ell(\varsigma)} \), and \( \varsigma \sim_d v \). Moreover, \( \varsigma \sim_d w \) and \( v \sim_d w \). By Theorem 49, \( \varsigma \uplus w, v \uplus w \in \varsigma(\text{target}(w)) \). From \( \varsigma \sim_d v \) we have \( \varsigma \uplus w \sim_d v \uplus w \) by Lemma 41. So \( \Sigma := \{ \varsigma \uplus w, v \uplus w \} \) is \( P \)-complete by Definition 36. By Theorem 37 there is a transition \( t' \) with \( \text{source}(t') = \text{target}(w) \) and \( \varsigma(t') = \Sigma \). Now \( t \sim_w t' \), as all conditions of Definition 51 are trivially satisfied. In particular, \( \ell(t) = \tau = \ell(t') \), by Lemma 35.

Finally suppose the third case applies, for some \( b \in B \). Let \( \Sigma = \varsigma(t) \uplus w \). Then \( \Sigma \subseteq \varsigma(\text{target}(w)) \) by Theorem 49. Note that \( \Sigma \) satisfies the first two requirements of Definition 36.3, since \( \varsigma(t) \) satifies them. By Lemma 41 the third requirement also holds for \( \Sigma \).

Now we extend \( \Sigma \) to \( \Sigma' \) by adding one synchron at a time. Namely, if there exists any \( \varsigma \in \varsigma(\text{target}(w)) \) with \( \ell(\varsigma) = b \) and \( \varsigma \sim_d v \) for every active synchron \( v \) currently in \( \Sigma \), then we add \( \varsigma \) to \( \Sigma \). The set \( \Sigma' \) has been obtained when no further such synchrons \( \varsigma \) can be found. By construction, \( \Sigma' \) satisfies the first four requirements of Definition 36.3.

In particular, a newly added \( b?-\)synchron will not affect any \( b-\)synchron already existing in \( \Sigma \). Note that according to Theorem 49, this \( b?-\)synchron must be either (a) a member of \( \text{new}(w) \) or (b) a member of \( \{ \varsigma(P) \}\varsigma(t) \uplus w \). In Case (a), it will be concurrent with all the existing \( b-\)synchrons in \( \Sigma \) thanks to Lemma 47. In Case (b), it will be \( \varsigma \uplus w \) for some \( \varsigma \in \varsigma(P) \\varsigma(t) \) with \( \varsigma \sim_d w \). Since \( \varsigma \notin \varsigma(t) \), by Definition 36 and Theorem 37 we can obtain \( v \in \kappa_\varsigma(t) \) such that \( \varsigma \sim_d v \). If \( v \sim_d w \), then \( v \uplus w \in \Sigma \) and, by Lemma 41, \( \varsigma \uplus w \sim_d v \uplus w \), contradicting the requirement that \( \varsigma \uplus w \) is not affected by any active synchron currently in \( \Sigma \). So \( v \sim_d w \). We obtain \( \xi \in \kappa_\varsigma(w) \) with \( \varsigma \sim_d \xi \).

1. If the common prefix shared by \( \varsigma \) and \( \nu \) is shorter than that shared by \( \nu \) and \( \xi \), we have \( \varsigma = \sigma \uplus \sigma' \nu = \sigma \uplus \sigma' \nu' \) and \( \xi = \sigma \uplus \sigma' \omega \) with \( \sigma, \sigma' \in \text{Arg}^*, \{ D, E \} = \{ D', E' \} = \{ L, R \} \), and \( \varsigma', \nu', \xi' \) synchrons. Then \( \varsigma \sim_d \xi \), contradicting \( \varsigma \sim_d w \).

2. If the common prefix shared by \( \varsigma \) and \( \nu \) is the same as that shared by \( \nu \) and \( \xi \), we have \( \varsigma = \sigma \uplus \sigma' \nu = \sigma \uplus \sigma' \nu' \) and \( \xi = \sigma \uplus \omega \xi' \) with \( \sigma, \sigma' \in \text{Arg}^*, \{ D, E \} = \{ L, R \} \), and \( \varsigma', \nu', \xi' \) synchrons. A \( b-\)synchrons in \( \Sigma \) must be \( \nu \uplus w \) for some \( \nu \in \varsigma(t) \) with \( \ell(\nu) = b \) and \( v \sim_d w \). From \( v \sim_d w \) we have \( v \sim_d \xi \); by Definition 36 and Theorem 37, \( v \sim_d \nu \). Thus \( v \) has a prefix \( \sigma' \nu \) and \( \nu \) has a prefix \( \sigma' \nu' \) with \( \{ D', E' \} = \{ L, R \} \). Moreover, \( \sigma' \) must be a proper prefix of \( \sigma \), as otherwise \( v \sim_d \xi \). Hence \( \varsigma \sim_d v \). By Lemma 41 \( \varsigma \uplus w \sim_d v \uplus w \).

3. If the common prefix shared by \( \varsigma \) and \( \nu \) is longer than that shared by \( \nu \) and \( \xi \), we have \( \varsigma = \sigma \uplus \sigma' \nu \varsigma' \nu = \sigma \uplus \sigma' \nu' \omega \nu' \) and \( \xi = \sigma \uplus \omega \xi' \) with \( \sigma, \sigma' \in \text{Arg}^*, \{ D, E \} = \{ D', E' \} = \{ L, R \} \), and \( \varsigma', \nu', \xi' \) synchrons. Then \( \varsigma \sim_d \xi \), contradicting \( \varsigma \sim_d w \).

Next we extend \( \Sigma' \) to \( \Sigma'' \) by adding one synchron at a time. Namely, if there exists any \( \varsigma \in \varsigma(\text{target}(w)) \) with \( \ell(\varsigma) = b \) and \( \varsigma \sim_d v \) for every active synchron \( v \) currently in \( \Sigma' \), then we add \( \varsigma \) to \( \Sigma' \). The set \( \Sigma'' \) has been obtained when no further such synchrons \( \varsigma \) can be found. By construction, \( \Sigma'' \) satisfies all requirements of Definition 36.3, and thus is \( P \)-complete.

By Theorem 37 there is a transition \( t' \) with \( \text{source}(t') = \text{target}(w) \) and \( \varsigma(t') = \Sigma'' \).

Now \( t \sim_w t' \), as all conditions of Definition 51 are satisfied. Regarding the last condition, if \( \kappa_\varsigma(t) \neq \emptyset \) then \( \kappa_\varsigma(t') \neq \emptyset \) and \( \ell(t) = b \neq \ell(t') \). If \( \kappa_\varsigma(t) = \emptyset \) then \( \kappa_\varsigma(t') = \emptyset \) and \( \ell(t), \ell(t') \in \{ b?, b \} \), by Lemma 35. Either way, the last condition holds.
Digression: A Successor Relation between Synchrons

In this section we provide an alternative form of Condition 4 of Definition 51, which does not use the function $\Theta$. We use it to relate our $\sim'$-relation with the $\sim$-relation from [9].

Definition 54 (Possible Successor Synchron [9]). A synchron $\zeta'$ is a possible successor of a synchron $\zeta$, notation $\zeta \sim \zeta'$, if either $\zeta' = \zeta$ or $\zeta' = \sigma_0 \zeta''$ with $\sigma \in \text{Arg}_f$, $D \in \{L, R\}$, and $\zeta''$ a synchron, and $\zeta' = \text{static}(\sigma)|_{\zeta''}$.

Lemma 55. Let $w \in Tr$, $P = \text{source}(w)$, $Q = \text{target}(w)$, $\zeta \in \zeta(P)$ and $\zeta' \in \zeta(Q)$, such that $\zeta \sim_d w$. Then $\zeta \sim \zeta'$ if $\zeta' = \zeta \oplus w$.

Proof. By Definition 40 $\zeta \sim \zeta \oplus w$, so 'only if' is trivial.

For 'if', suppose $\zeta \sim \zeta'$. Then $\zeta'$ and $\zeta \oplus w$ are both obtained from $\zeta$ by deleting a prefix of their dynamic arguments. So $\zeta' = \sigma_1 \sigma_2 \zeta_3$ and $\zeta \oplus w = \sigma_1 \sigma_2 \zeta_3 w$ with either $\sigma_2 = \text{static}(\sigma_2)$ or $\sigma_2 = \text{static}(\sigma_2')$. Moreover, if $\sigma_2$ is non-empty, then $\zeta_3$ must start with an argument $[a]$ or $[\alpha]$. Furthermore, since $\zeta \oplus w \in \zeta(Q)$ by Theorem 49, both $\zeta'$ and $\zeta \oplus w$ describe paths in the (unfolded) parse tree of $Q$. So the first argument on which they differ, if any, must be $o_P$ versus $o_{Pn}$ for the same binary $ABcdE$ operator $oP \in \{+,[\alpha]\}$. Together, these conditions imply that $\zeta' = \zeta \oplus w$.

Consequently, Condition 4 of Definition 51 can be restated as

4. for all $\zeta \in \zeta(t)$ with $\zeta \sim_d w$, there exists a $\zeta' \in \zeta(t')$ with $\zeta \sim \zeta'$.

Recall that $Tr^{**} \subseteq Tr$ is the set of transitions $t$ with $t(t) \notin \mathcal{B} \cup \mathcal{R}$. In [9] a binary relation $\sim \subseteq Tr^{**} \times Tr^{**}$ was defined by $t \sim t'$ iff $|n_\zeta(t)| = |n_\zeta(t')|$ and $\forall \zeta' \in n_\zeta(t')$. $\exists \zeta \in n_\zeta(t)$. $\zeta \sim \zeta'$.

By Lemmas 52 and 55 it follows that $t \sim' t'$ for $t, t' \in Tr^{**}$ and $w \in Tr$ implies $t \sim t'$.

B.5 The two Successor Relations between Transitions Coincide

Theorems 56 and 57 below yield the main result of this appendix, that $\sim$ equals $\sim'$.

Theorem 56. $\sim \subseteq \sim'$. I.e., if $\chi \sim \chi'$ then $\chi \sim' \chi'$.

Proof. Since the $\sim$ relation is defined inductively, $\chi \sim \chi'$ must stem from some rules in Definition 20, which means at least one statement below holds for some $t, t', u, v, w, v \in Tr$, $P, Q \in \mathcal{P}$, $\alpha, L, f, A, b, r$ with $\text{source}(t) = \text{source}(v) = P$, $\text{source}(u) = \text{source}(w) = Q$, $\text{source}(t') = \text{target}(v)$, $\text{source}(u') = \text{target}(w)$, $\alpha \in \text{Act}$, $L \subseteq \mathcal{P} \cup \mathcal{P}$, $f$ a relabelling, $A \in \mathcal{A}$, $b \in \mathcal{B}$ and $r \in \mathcal{R}$.

1. $\ell(\zeta) \in \mathcal{B} \cup \mathcal{T}$, source(\zeta) = source(\chi) and $\chi' = \chi$
2. $\chi = b'P$, $\zeta = \rho P$ and $\chi' = t$ with $\ell(t) \in \{b', b\}$
3. $\chi = \text{bca}P$, $\zeta = \text{a}P$ and $\chi' = t$ with $\ell(t) \in \{b', b\}$
4. $\chi = \text{t + u}$, $\zeta = \text{v + Q}$ and $\chi' = t'$ with $\ell(v) \notin \mathcal{T}$ and $t \sim_{v+} t'$
5. $\chi = \text{P + u}$, $\zeta = \text{P + w}$ and $\chi' = u'$ with $\ell(w) \notin \mathcal{T}$ and $u \sim_{w} u'$
6. $\chi = \text{t + u}$, $\zeta = \text{P + w}$ and $\chi' = u'$ with $\ell(w) \notin \mathcal{T}$ and $u \sim_{w} u'$
7. $\chi = \text{t+Q}$, $\zeta = \text{P+Q}$ and $\chi' = \text{t'}Q$ with $t \sim_{v} t'$
8. $\chi = \text{t+Q}$, $\zeta = \text{v+Q}$ and $\chi' = \text{t'}Q$ with $t \sim_{v} t'$
9. $\chi = \text{P+Q}$, $\zeta = \text{v+Q}$ and $\chi' = \text{t'}Q$ with $t \sim_{v} t'$
10. $\chi = \text{P+Q}$, $\zeta = \text{v+Q}$ and $\chi' = \text{t'}Q$ with $t \sim_{v} t'$
8.c \( \chi = t|u, \zeta = v|Q \) and \( \chi' = t'|u \) with \( t \sim_v t' \);
9.a \( \chi = P|u, \zeta = P|w \) and \( \chi' = P|u' \) with \( u \sim_w u' \);
9.b \( \chi = P|u, \zeta = v|w \) and \( \chi' = \text{target}(v)|u' \) with \( u \sim_w u' \);
9.c \( \chi = t|u, \zeta = P|w \) and \( \chi' = t|u' \) with \( u \sim_w u' \);
10.a \( \chi = t|u, \zeta = v|w \) and \( \chi' = t'|u' \) with \( t \sim_v t' \) and \( u \sim_w u' \);
11.a \( \chi = t\ell, \zeta = v\ell \) and \( \chi' = t'|u' \) with \( \ell(v) \in \text{Act} \) and \( t \sim_v t' \);
11.b \( \chi = t|f, \zeta = v|f \) and \( \chi' = t'|f \) with \( \ell(v) \in \text{Act} \) and \( t \sim_v t' \);
11.c \( \chi = \text{Act}, \zeta = \ell v \) and \( \chi' = t' \) with \( \ell(v) \in \text{Act} \) and \( t \sim_v t' \);
11.d \( \chi = \ell v, \zeta = v \ell r \) and \( \chi' = t' \) with \( \ell(v) \in \text{Act} \) and \( t \sim_v t' \).

The numbers of the above statements correspond to the numbers of the rules in Definition 20. For example, Statement 2.a or 2.b holds if \( \chi \sim_\zeta \chi' \) stems from Rule 2.

It suffices to prove that each statement above implies \( \chi \sim_\zeta \chi' \) under the assumptions \( t \sim_v t' \implies t \sim_\psi t' \) and \( u \sim_w u' \). This gives us a structural induction proof of Theorem 56. Namely, cases for Statements 1.a, 2.a, 2.b, 5.a, 6.a, 7.a and 7.b – where the two assumptions will not be used – form the induction base, while the other cases represent the induction step with the two assumptions being the induction hypothesis.

By Definition 51, in each case we need to prove
(a) \( \text{source}(\chi) = \text{source}(\zeta) \),
(b) \( \text{source}(\chi') = \text{target}(\zeta) \),
(c) \( \chi \sim_\psi \zeta \),
(d) for all \( \zeta \in \zeta(\chi) \) with \( \zeta \sim_d \zeta \), one has \( \zeta \circ_\chi \zeta \in \zeta(\chi') \), and
(e) \( \ell(\chi) = \ell(\chi') \cup \exists b \in B. \{\ell(\chi), \ell(\chi')\} = \{b?, b\} \).

Below we use the number of statements for cases.

**Case 1.a:**
- (a) is given in the statement.
- From \( \ell(\zeta) \in B : \cup F \) we have \( \text{target}(\zeta) = \text{source}(\zeta) \). With \( \text{source}(\zeta) = \text{source}(\chi) \) and \( \chi' = \chi \) we have (b).
- From \( \ell(\zeta) \in B : \cup F \) we have \( \alpha_\zeta(\zeta) = \emptyset \). Thus (c) trivially holds.
- Suppose \( \zeta \in \zeta(\chi) \). From \( \ell(\zeta) \in B : \cup F \) we have \( \zeta \circ_\chi \zeta = \zeta \). Using \( \chi' = \chi \) we have (d).
- From \( \chi' = \chi \) we have \( \ell(\chi) = \ell(\chi') \). Thus (e) holds.

**Case 2.a:**
- \( \text{source}(\chi) = b!P = \text{source}(\zeta) \).
- \( \text{source}(\chi') = P = \text{target}(\zeta) \).
- We have \( \ell(\chi) = b? \). Then \( n_\zeta(\chi) = \emptyset \). Thus (c) trivially holds.
- We have \( \langle bP \rangle \in \alpha_\zeta(\zeta) \) and \( \forall \zeta \in \zeta(\chi), \zeta \not\in_d \langle bP \rangle \). Thus (d) trivially holds.
- We have \( \ell(\chi) = b? \) and \( \ell(\chi') \in \{b?, b\} \). Thus (e) holds.

**Case 2.b:**
- \( \text{source}(\chi) = \alpha P = \text{source}(\zeta) \).
- \( \text{source}(\chi') = P = \text{target}(\zeta) \).
- We have \( \ell(\chi) = b? \). Then \( n_\zeta(\chi) = \emptyset \). Thus (c) trivially holds.
- We have \( \langle bP \rangle \in \alpha_\zeta(\zeta) \) and \( \forall \zeta \in \zeta(\chi), \zeta \not\in_d \langle bP \rangle \). Thus (d) trivially holds.
- We have \( \ell(\chi) = b? \) and \( \ell(\chi') \in \{b?, b\} \). Thus (e) holds.

**Case 3.a:**
- \( \text{source}(\chi) = P + Q = \text{source}(\zeta) \).
Thus (d) holds.

We have $|\varsigma| = |\varsigma(t)|$ and $\varsigma(t) \in \alpha(\varsigma)$. Then $\varsigma = \eta_{\varsigma} \varsigma(t)$ and $\varsigma(t) \in \alpha(\varsigma)$. From $t \sim_{\varsigma} t'$ we have $\varsigma(t) = \varsigma(t')$. Thus (e) holds.

Suppose $\varsigma \in \varsigma(t)$ and $\varsigma \sim_{\varsigma} \varsigma(t)$. Then $\varsigma = \eta_{\varsigma} \varsigma(t)$ for some $\varsigma(t) \in \varsigma(t)$. From $t \sim_{\varsigma} t'$ we have $\varsigma(t) = \varsigma(t')$. Thus (d) holds.

The proof is similar to that for Case 3.a and is omitted.

Case 4.a: The proof is similar to that for Case 3.a and is omitted.

Case 4.b: The proof is similar to that for Case 3.b and is omitted.

Case 5.a:

source($\chi$) = $P + Q$ = source($\zeta$).

source($\chi'$) = target($v$) = target($\zeta$).

We have $\ell(\chi) \in \mathcal{R}$. Then $n_\varsigma(\chi) = \emptyset$. Thus (c) trivially holds.

Suppose $\varsigma \in \varsigma(\chi)$ and $\varsigma \sim_{\varsigma} \varsigma(t)$. Then $\varsigma = \eta_{\varsigma} \varsigma(t)$ for some $\varsigma(t) \in \varsigma(t)$. From $t \sim_{\varsigma} t'$ we have $\varsigma(t) = \varsigma(t')$. Thus (d) holds.

The proof is similar to that for Case 5.a and is omitted.

Case 6.a: The proof is similar to that for Case 5.a and is omitted.

Case 7.a:

source($\chi$) = $P|Q = source(\zeta)$.

source($\chi'$) = $P|target(w) = target(\zeta)$.

We have that all synchrons in $n_\varsigma(\chi)$ are $|\varsigma$-prefixed and all synchrons in $\alpha(\varsigma)$, if any, are $|\varsigma$-prefixed. Thus (c) holds.

Suppose $\varsigma \in \varsigma(\chi)$ and $\varsigma \sim_{\varsigma} \varsigma(t)$. Then $\varsigma = \eta_{\varsigma} \varsigma(t)$ for some $\varsigma(t) \in \varsigma(t)$. If $\ell(\varsigma) \in \tilde{\mathcal{S}}$, then $\varsigma \sim_{\varsigma} \varsigma(t) = \varsigma(t)$. Otherwise, we have that all synchrons in $\alpha(\varsigma)$ are $|\varsigma$-prefixed. Using that $\varsigma \sim_{\varsigma} \varsigma(t) = \varsigma(t)$, we have $\varsigma \sim_{\varsigma} \varsigma(t) = \varsigma(t)$. Thus (d) holds.

We have $\ell(\chi) = \ell(t) \in \ell(\chi')$. Thus (e) holds.

Case 7.b: The proof is similar to that for Case 7.a and is omitted.

Case 8.a:

source($\chi$) = $P|Q = source(\zeta)$.

source($\chi'$) = target($v$)|$Q = target(\zeta)$.  

R.J. van Glabbeek, P. Höfner and W. Wang 31
Suppose \( \zeta \in n_\chi(\chi) \) and \( v \in a_\chi(\zeta) \). Then \( \zeta = |_l^v \zeta \) and \( v = |_l^v v \) for some \( \zeta \in n_\chi(t) \) and \( v \in a_\chi(v) \). Then \( \zeta \sim_d v \). Thus \( (e) \) holds.

Suppose \( \zeta \in s_\chi(\chi) \) and \( \sim_d \zeta \). Then \( \zeta = |_l^v \zeta \) for some \( \zeta \in n_\chi(t) \) with \( \zeta \sim_d v \).

If \( \ell(\zeta) = \ell(v) \in \mathcal{B} \cup \hat{\mathcal{F}} \), then \( \zeta \sim_d = \zeta = |_l^v \zeta \in \approx(t) \). Also, from \( t \sim_v t' \) we have \( t' = t \). Thus \( (d) \) holds.

Case 8.a: The proof is similar to that for Cases 7.b and 8.a/b, and is omitted.

Case 8.b: The proof is similar to that for Case 8.a and is omitted.

Case 8.c: The proof is similar to that for Case 8.c and is omitted.

Case 8.d: The proof is similar to that for Cases 8.a and 8.b, and is omitted.

Case 8.e: The proof is similar to that for Case 8.a and is omitted.

Case 9.a: The proof is similar to that for Case 9.a and is omitted.

Case 9.b: The proof is similar to that for Case 9.b and is omitted.

Case 9.c: The proof is similar to that for Case 9.c and is omitted.

Case 10.a: The proof is similar to that for Cases 10.a and 10.b, and is omitted.

Case 11.a: The proof is similar to that for Case 11.a and is omitted.

Case 11.b: The proof is similar to that for Case 11.b and is omitted.

Case 11.c: The proof is similar to that for Case 3.a and is omitted.

Case 11.d: The proof is similar to that for Case 11.c and is omitted.

\[ \sim' \subseteq \sim. \] I.e., if \( \chi \sim'_\zeta \chi' \) then \( \chi \sim_\zeta \chi' \).

**Proof.** First suppose \( \ell(\zeta) \in \mathcal{B} \cup \hat{\mathcal{F}} \). From \( \chi \sim'_\zeta \chi' \) we have \( \text{source}(\chi') = \text{target}(\zeta) = \text{source}(\zeta) = \text{source}(\chi) \). By Definition 20(1) and Lemma 31, it suffices to show \( \zeta = \zeta(\chi') = \zeta(\chi) \).

By Definition 51 and Definition 40, \( \zeta(\chi') \geq \zeta(\chi) \). Suppose \( \zeta \in \zeta(\chi') \setminus \zeta(\chi) \), then \( \ell(\chi') \in \mathcal{R} \cup \hat{\mathcal{F}} \). and \( \ell(\zeta) \in \mathcal{R} \cup \hat{\mathcal{F}} \) by Lemma 52. Then \( \zeta(\chi) \) is not \( \mathcal{P} \)-complete by Definition 36; we have a contradiction with Theorem 37. So \( \zeta(\chi') = \zeta(\chi) \).

Now suppose \( \ell(\zeta) \in \text{Act} \). We proceed by structural induction on \( \zeta(\zeta) \), using the same well-founded order \( < \) on sets of synchrons as in the proof of Theorem 37.

**Induction base:** Suppose \( \zeta(\zeta) = \{ \ell(\zeta) \} \) for some \( \alpha \in \text{Act} \) and \( Q \in \mathcal{P} \). Then \( \zeta = (\ell(\zeta) \ldots \ell(\zeta)) \) and \( \text{source}(\chi) = \text{source}(\zeta) = \alpha.Q \). By Definition 51(3) we have \( \chi \sim' \zeta \). Since all synchrons in \( \chi \)
will be affected by ζ, nς(χ) must be empty; i.e., ℓ(χ) ∈ R? ∪ R. So either (1) α = b? and
χ = (c→)P or (2) α ≠ b? and χ = bα.P, with b ∈ R. In both cases, by Definition 51(5), we
have ℓ(χ′) ∈ {b?, b!}. Thus χ ↝ ρ χ′ by Definition 20(2).

Induction step: Given ζ ∈ Tr, we assume that (IH) Υ ↝ ρ ζ′, Υ′ → Υ ↝ ρ ζ′, for all
Τ, ζ′, Υ′ ∈ Tr such that ζ(ζ′) ≤ ρ ζ(ζ′).

Suppose ζ(ζ) = +1Σn for some Σn. Then ζ = v + Q and source(χ) = source(ζ) = P + Q for
some P, Q ∈ P and v ∈ en(P) with ζ(ς) = Σn. So either (1) χ = t + Q, (2) χ = P + u or (3)
χ = t + u, with t ∈ en(P) and u ∈ en(Q).

In Cases (1) and (3), by Definition 20(3) and (IH), it suffices to prove t ↝ u χ′.

source(t) = source(v) follows from source(χ) = source(ζ).

source(χ′) = target(v) follows from source(χ′) = target(ζ) and ℓ(ζ) ∈ Act.

t ↝ u v follows from χ ↝ ρ χ′.

From ℓ(ζ) ∈ Act, we have aς(v) ≠ ∅ or aς(ζ). Using that +1ς @ +1υ = ς @υ whenever
ς ↝ u υ, we have ℓ(t) @υ = ℓ(χ) @υ ⊆ ς(χ′).

ℓ(t) = ℓ(χ′) ∨ ∃b ∈ R. {ℓ(t), ℓ(χ′)} = {b?, b!} follows from ℓ(χ) = ℓ(χ′) ∨ ∃b ∈ R.

In Case (1), we have ℓ(χ′) = ℓ(χ) by (IH) and Definition 20(8).

In Case (2), as in Case (1), using that |u@ς|v = |u@ς|v, we have that χ′ = target(υ)|u′
for some u′ ∈ en(Q) with ς(u′) = ς(u). By Lemma 31, we have u′ = u. Thus χ ↝ ρ χ′ by
Definition 20(7).

In Case (3), we have ς(χ′) @ς(ζ) = |u|ς(υ) ∪ |u|ς(υ) ⊆ ς(χ′) by Definition 51(4). Then
ς′ = ℓ(t)′ for some ℓ(t) ∈ en(target(υ)) and u′ ∈ en(Q) with ς(ℓ(t)) = ς(ℓ(t)) @υ and ς(u′) = ς(u).

Note that ς(ℓ(t)) won’t be empty regardless of whether ℓ(t) ∈ R? ∪ R. If ς(ℓ(t)) ⊊ ς(υ), then
either, when ℓ(t) ∈ C ∪ C ∪ C ∪ C ∪ C ∪ C, we have ℓ(υ′) = τ by Lemma 35, preventing ℓ(t)′, u′
from synchronising, or, when ℓ(t) ∈ B? ∪ R? ∪ R, Definition 36 and Theorem 37 are violated.

Hence we have ς(υ′) = ς(υ) and thus, by Lemma 31, u′ = u. By Definition 20(8) and (IH), it
suffices to prove t ↝ u χ′. All conditions except Item 5 of Definition 51 are trivially satisfied.

We now show that Condition 5 also holds for t, v, ℓ(t).
If $\ell(t) \in \{b?, b:\}$ and $\ell(u) \in \{b?, b:\}$ for some $b \in \mathcal{B}$, then $\ell(\chi) \in \{b?, b:\}$. By Definition 51(5) we have $\ell(\chi') \in \{b?, b:\}$. Thus $\ell(t') \in \{b?, b:\}$ by Lemma 35.

Suppose $\varsigma(\zeta) = |r\Sigma_R|$ for some $\Sigma_R$. The proof is similar to that of the previous case.

Suppose $\varsigma(\zeta) = |L\Sigma_L \cup |r\Sigma_R|$ for some non-empty $\Sigma_L, \Sigma_R$. The proof is similar to that of the previous two cases.

Suppose $\varsigma(\zeta) = \langle \Sigma' \rangle$ for some $L \subseteq \mathcal{C} \cup \mathcal{F}$ and $\Sigma'$. The proof is similar to that for the case where $\zeta = v|Q$ and $\chi = t|Q$.

Suppose $\varsigma(\zeta) = [f]\Sigma'$ for some relabelling $f$ and $\Sigma'$. The proof is similar to that of the previous case.

Suppose $\varsigma(\zeta) = A:\Sigma'$ for some $A \in \mathcal{A}$ and $\Sigma'$. The proof is similar to that for the case where $\zeta = v + Q$ and $\chi = t + Q$.

Suppose $\varsigma(w) = ^{s}\Sigma'$ for some $r \in \mathcal{F}$ and $\Sigma'$. The proof is similar to that of the previous case.
