We present a density-functional theory for the one dimensional harmonically trapped Bose-Fermi mixture with repulsive contact interactions. The ground state density distribution of each component is obtained by solving the Kohn-Sham equations numerically based on the Local Density Approximation and the exact solution for the homogeneous system given by Bethe ansatz method.

I. INTRODUCTION

Ultracold atomic gases provide a highly controllable testing ground to study fundamental problems in quantum many body physics [1] and many experimental observations can be compared directly with exactly solvable theories. The degenerate quantum gases with multi-component in low spatial dimensions, especially in one dimension (1D), become one of the growing interesting topics [2]. Multi-component gases can be mixture of the same species of atoms with different hyperfine states, i.e. spinor condensate, or mixture of different species of atoms. The competition between the intra- and inter-species interaction makes the mixture system more complicated and there exhibit richer physical phenomena than its single-component counterpart. Bose-Fermi mixture is originally realized in experiments as a result of sympathetic cooling technique, i.e., cooling the fermions to quantum degeneracy through the mediation of bosons [3–7]. Then many theoretical studies have been performed on three dimensional mixture, dealing with the phase separation [8], pairing [9], superfluids and Mott insulators transition [10], BEC and Bardeen-Cooper-Schrieffer crossover [11], etc. On the other hand, 1D systems attract attentions for the simplicity of theoretical models and for the significance of quantum correlation effects therein [12]. Experimentally the 1D systems can be realized by confining the cold atoms in two dimensional optical lattices or in strong anisotropic magnetic trap [13]. The interaction among the atoms can be tuned in the whole regime of interaction strength via the magnetic Feshbach resonance and controlling the transverse confinement of magnetic trap [14]. Interestingly enough, the properties of these system, including the ground state, elementary excitations as well as thermodynamics, are sometimes fairly well captured by the exactly solvable models studied a few decades ago [13].

Many theories have studied the 1D Bose-Fermi mixture both homogeneous and trapped gas in external potentials. When the system is homogeneous, Das [10] early plots the ground state phase diagram based on the mean-field theory, which predicts the occurrence of phase separation (i.e., demixing) of the two components. Luttinger liquid formalism shows that for strong enough repulsion the two components of the mixture, with bosons either a quasicondensate or impenetrable particles, repel each other sufficiently to demix [17]. But the exact Bethe ansatz solution for the 1D mixture with equal mass and equal coupling constants points out the absence of demixing [18, 19]. It indicates that mean-field theory and Luttinger liquid theory are reliable only for very weak interaction. With the system loaded in optical lattices, the phase diagram and correlation functions have been investigated with the bosonization method [20] and quantum Monte Carlo (MC) simulation [21]. For the trapped system, the local density approximation (LDA) on the Bethe ansatz solution shows that the harmonic trap 1D mixture would partially demix for strong repulsive interaction [19]. The finite temperature Yang-Yang thermodynamics and the quantum criticality analysis based on thermodynamic Bethe ansatz (TBA) both support the description of phase separation [22]. In the infinitely strong interaction limit, i.e. the Tonks-Girardeau (TG) regime, Bose-Fermi mapping method [23] gives a result that the density profiles display no demixing among the two component, where the exact ground state is highly degenerate and the most symmetrical one is chosen [24–26]. Later detailed calculations are done for all degenerate manifolds of the ground state [27] and the conclusion of nondemixing remains for the mixture in TG limit.

So far a method is not available for 1D trapped Bose-Fermi mixture suitable for the whole repulsive interaction regime. Numerical simulations such as Density Matrix Renormalization Group (DMRG) and quantum
MC are however limited to few atom numbers in lattice models [21, 27]. In this paper, we develop Hohenberg-Kohn-Sham Density-functional theory (DFT) to investigate the ground state properties of 1D harmonically trapped Bose-Fermi mixture. It is well known that DFT is a successful and widely used approach for treating the electron systems with long range Coulomb interaction [28, 29]. Recently it has been successfully generalized to cold atom systems with short-range contact interaction for three dimensional bosonic atoms [30, 31] and three dimensional Bose-Fermi mixture [32]. In the framework of DFT, in order to investigate the ground state properties of an inhomogeneous interacting system, a homogeneous interacting system is often needed in the process of local density approximation (LDA) for the exchange correlation energy [28]. Because Bethe ansatz method can give exact solution for 1D homogeneous systems, several authors developed the DFT based on Bethe ansatz results to solve the 1D Bosons [31, 33, 34] and 1D Fermi cold atom systems [35, 36]. Here we apply this method for 1D Bose-Fermi mixture. As can be seen below, the key points of our scheme include a suitable fitting formula for the ground state energy and appropriate choices of the functional orbitals for boson and fermions.

The paper is organized as follows. In Sec. II we derive the universal Kohn-Sham equations with LDA for 1D Bose-Fermi mixture and then present the expression of exchange-correlation energy. From the exact result of Bethe ansatz for homogeneous gas with equal masses of atoms and equal interaction of boson-boson and boson-fermion we find a fitting formula for the ground state energy to simplify the numerical iterations. Then the equations are solved numerically and the ground state energy and density distribution are discussed in Sec. III. Finally we conclude our result in the last section.

II. THEORY

A. Kohn-Sham equations

We consider a 1D trapped mixture of \( N_B \) bosons and \( N_F \) spin-polarized fermions with two-body contact interactions. \( N = N_B + N_F \) is the total atom number. The system is described by the Hamiltonian

\[
H = \sum_{i=1}^{N_B} \left[ -\frac{\hbar^2}{2m_B} \frac{d^2}{dx_i^2} + V_B(x_i) \right] \\
+ \sum_{j=1}^{N_F} \left[ -\frac{\hbar^2}{2m_F} \frac{d^2}{dx_j^2} + V_F(x_j) \right] \\
+ \frac{g_{BB}}{2} \sum_{i,\nu=1}^{N_B} \delta(x_i - x_\nu) \\
+ \frac{g_{BF}}{2} \sum_{i=1}^{N_B} \sum_{j=1}^{N_F} \delta(x_i - x_j).
\]

Here \( m_B, m_F \) are boson and fermion masses, \( V_B(x), V_F(x) \) are external potentials, and \( g_{BB}, g_{BF} \) are the effective 1D Bose-Bose and Bose-Fermi interaction parameters, which can be tuned experimentally [14, 27]. The Fermi-Fermi interaction is not considered because the Pauli exclusion principle suppresses the contact s-wave scattering and their p-wave scattering can be neglected.

According to the Hohenberg-Kohn theorem I of DFT [28], the ground state density of a bound system of interacting particles in some external potential determines this potential uniquely. It thus gives us the full Hamiltonian \( H \) and particle number \( N \). Hence the density determines implicitly all properties derivable from \( H \) through the solution of the time-independent or time-dependent Schrödinger equation. Though proved originally for Fermions, the theorem can be straightforwardly generalized to Bosons as well as the mixture of Bosons and Fermions studied here. Denote the densities of bosons and fermions as \( n_B(x) \) and \( n_F(x) \), respectively, the total density is then obviously \( n(x) = n_B(x) + n_F(x) \). The number of Bosons and Fermions are conserved separately, i.e. \( \int n_B(x) \, dx = N_B \), \( \int n_F(x) \, dx = N_F \) and \( \int n(x) \, dx = N \). The ground state energy, defined as \( \langle g|H|g \rangle \) the ground state of system, is a functional of the densities \( E_0 [n_B(x), n_F(x)] \), which can be decomposed as

\[
E_0 = T^{ref}_B [n_B, n_F] + T^{ref}_F [n_B, n_F] \\
+ \int dx n_B(x) V_B(x) + \int dx n_F(x) V_F(x) \\
+ \frac{g_{BB}}{2} \int dx n_B^2(x) + g_{BF} \int dx n_B(x) n_F(x) \\
+ E_{xc} [n_B, n_F].
\]

The first two terms are Bose and Fermi kinetic energies of a reference noninteracting system. The next two terms in the second row are external potential energies and those in the third row are Hartree-Fock energies (i.e., the mean-field approximation of the interaction energy). The last term is the exchange correlation energy which includes all the contributions to the interaction energy beyond mean-field theory.

We assume the Bosons are in a quasi-condensate state and Fermions are in normal state. Thus we introduce a single Bose functional orbital \( \phi(x) \) and \( N_F \) Fermi functional orbitals \( \psi_j(x) (j = 1 \cdots N_F) \) which are orthogonal and normalized. This is different from the way of Ref. [33] where only one condensed orbital of fermionic pair is considered for the mixture of bosons and paired two-component fermions in superfluid state or BCS state. With \( \phi(x) \) and \( \psi_j(x) \), the densities are expressed as

\[
n_B(x) = N_B \phi^*(x) \phi(x), \\
n_F(x) = \sum_{j=1}^{N_F} \psi_j^*(x) \psi_j(x).
\]
and the kinetic energies are
\[
T_B^{\text{ref}} = -N_B \int dx \phi^* (x) \frac{\hbar^2}{2m_B} \frac{d^2}{dx^2} \phi (x),
\]
\[
T_F^{\text{ref}} = - \sum_{j=1}^{N_F} \int dx \psi_j^* (x) \frac{\hbar^2}{2m_F} \frac{d^2}{dx^2} \psi_j (x).
\]

As far as the exchange correlation energy \(E_{xc} [n_B, n_F]\) is concerned, when the confinement is weak, we adopt the Local Density Approximation (LDA), i.e., the system can be assumed locally homogeneous at each point \(x\) in the external trap. In this way \(E_{xc}\) is approximated with an integral over the exchange-correlation energy per atom of a homogeneous interacting mixture \(\varepsilon_{xc}^\text{hom} (n_B, n_F)\)
\[
E_{xc} \approx \int dx n (x) \varepsilon_{xc}^\text{hom} (n_B, n_F),
\]
where the densities \(n_B, n_F\) are taken at point \(x\).

For such a homogeneous interacting mixture,
\[
\varepsilon_{xc}^\text{hom} = \varepsilon^\text{hom} - \varepsilon_M^\text{hom} - \kappa_s^\text{hom},
\]
where \(\varepsilon^\text{hom}\) is the ground state energy per atom; \(\varepsilon_M^\text{hom} = g_{BB} n_B^2 / 2 + g_{BF} n_B n_F / n\) is the mean field interaction energy per atom; \(\kappa_s^\text{hom} = \hbar^2 \pi^2 n_F^3 / 6m_F n\) is the kinetic pressure terms, i.e., the total kinetic energy divided by the total number of fermions and bosons in a noninteracting homogeneous mixture. Here the kinetic energy of the bosons is easily shown to be zero and the kinetic energy comes solely from the exclusive quantum state occupation of fermions.

Hohenberg-Kohn theorem II \(\cite{28}\) guarantees that the ground state density distributions is determined by variationally minimizing \(E_0\) with respect to \(n_B (x)\) and \(n_F (x)\), which is equivalent to a variational calculation of \(\varepsilon^\text{hom}\) with respect to the Bose and Fermi functional orbitals \(\phi^*, \psi_j^*\). After substituting \(\varepsilon^\text{hom}\) into \(\varepsilon_M\) and substituting \(\varepsilon^\text{hom}\) into \(\varepsilon_M^\text{hom}\), we carry out the functional derivatives
\[
\delta \left( E_0 - \epsilon n_B \right) \int dx \phi^* (x) (\phi - 1) / \delta \phi^* = 0,
\]
\[
\delta \left( E_0 - \sum_{j=1}^{N_F} n_j \left( \psi_j^* dx \psi_j - 1 \right) / \delta \psi_j^* = 0,
\]
where \(\epsilon\) and \(n_j (j = 1, 2, \cdots N_F)\) are Lagrange multipliers conserving the normalization of \(\phi (x)\) and \(\psi_j (x)\). Then we can get the Kohn-Sham equations (KSEs)
\[
\left( - \frac{\hbar^2}{2m_B} \frac{d^2}{dx^2} + V_B (x) + \mu_B^\text{hom} \left( [n_B, n_F] ; x \right) \right) \phi (x) = \epsilon \phi (x),
\]
\[
\left( - \frac{\hbar^2}{2m_F} \frac{d^2}{dx^2} + V_F (x) - \frac{\hbar^2}{2m_F} \pi^2 n_F^2 (x) + \mu_F^\text{hom} \left( [n_B, n_F] ; x \right) \right) \psi_j (x) = \eta_j \psi_j (x).
\]

Here \(\mu_B^\text{hom} = \partial (n_B^\text{hom}) / \partial n_B\) and \(\mu_F^\text{hom} = \partial (n_F^\text{hom}) / \partial n_F\) are Bose and Fermi chemical potentials of a homogeneous interacting mixture. Physically \(\epsilon\) and \(n_j\) are the lowest eigenvalues of KSE. In \(\varepsilon_{xc}\), the sum in \(n_F (x)\) runs over the occupied orbitals \(\psi_j\) with lowest \(n_j\).

Left multiplying \(\psi_j^*\) on both sides of \(\varepsilon_{xc}\), performing summation over \(j\) and integrating over \(x\), we get an expression of \(T_F^{\text{ref}}\) defined in \(\varepsilon_{xc}\). Analogously from the normalization of \(\phi (x)\) we may get an expression for \(T_F^{\text{ref}}\) defined in \(\varepsilon_{xc}\). Inserting these two kinetic terms into \(\varepsilon_{xc}\), the ground state energy \(\varepsilon_{xc}\) is expressed as a function of \(\epsilon\) and \(n_j\)
\[
E_0 = N_B \epsilon + \sum_{j=1}^{N_F} n_j
\]
\[
\quad + \int n (x) \varepsilon_{xc}^\text{hom} (x) dx - \int n_B (x) \mu_B^\text{hom} (x) dx
\]
\[
\quad - \int n_F (x) \mu_F^\text{hom} (x) dx + \frac{\hbar^2 \pi^2}{2m_B} \int n_F^2 (x) dx(11)
\]

If \(\varepsilon_{xc} [n_B, n_F]\) are known, we can solve the KSEs together with \(\varepsilon_{xc}\) to find the density distributions \(n_B (x), n_F (x)\) and then calculate the ground state energy \(E_0\) from \(\varepsilon_{xc}\). In the following we present the result of \(\varepsilon_{xc} [n_B, n_F]\) by means of the Bethe ansatz method.

B. Ground state energy of homogeneous system

In the absence of an external trap the system is homogeneous, which can be solved exactly via Bethe ansatz method for a much restrictive but simple case
\[
g_{BB} = g_{BF} = g > 0,
\]
\[
m_B = m_F = m.
\]

It describes the situation that the interactions of Boson-Boson and Boson-Fermion are repulsive with the same strength, and the masses of Boson and Fermion are the same too. Detailed possible ways to realize this situation in cold atom experiments have been considered previously \(\cite{19}\). The first condition can be satisfied using the combination of Feshbach resonance (to control the
interactions) and appropriate choice of the tuning of the trapping laser frequencies (to adjust the the ratio of the radial confinement of Bosons and Fermions). The second condition is approximately satisfied with a mixture of two isotopes of a species of atoms. Isotope mixture is widely used in experiment for it can avoid the gravitational sag of an external potential caused by different masses. The experiments have realized 3D isotope mixtures $^{6}$Li+$^{7}$Li [4], $^{173}$Yb+$^{174}$Yb [6], $^{40}$K+$^{41}$K [7] and we see no obvious obstacles in 1D. Under these two conditions, the Hamiltonian of 1D homogeneous Bose-Fermi mixture is

$$H = -\frac{\hbar^2}{2m} \sum_{i=1}^{N} \frac{d^2}{dx_i^2} + g \sum_{i<j} \delta (x_i - x_j).$$

This model is solved by means of Bethe ansatz method by Lai and Yang in 1971 for the 1D mixture of bosons and spin-$1/2$ fermions [18]. Imambekov and Demler investigated the ground state properties in detail for the 1D mixture of bosons and spin-1/2 fermions [19]. Imambekov and Demler in-vestigated the ground state properties in detail for the 1D mixture of bosons and spin-polarized fermions [19] and extensive studies have been done in [22, 39, 41] including the thermodynamics and correlation functions. Here we briefly review the main results of [18, 19, 41] which are readily used as the homogeneous reference system in our DFT theory. Under the periodic boundary condition and in the thermodynamical limit (the system size and the number of atoms are infinitely large but the atomic densities are kept finite), the ground state Bethe ansatz integral equations are

$$\rho (k) = \frac{1}{2\pi} \left[ 1 + \int_{-B}^{B} \frac{c(\Lambda) d\Lambda}{c^2/4 + (\Lambda - k)^2} \right],$$

$$\sigma (\Lambda) = \frac{1}{2\pi} \int_{-Q}^{Q} \frac{c(\Lambda) d\Lambda}{c^2/4 + (\Lambda - k)^2}.$$  \tag{14}

where $c = mg/\hbar^2$, $k$ and $\Lambda$ are the quasi-momenta and spectral parameters and $\rho (k)$ and $\sigma (\Lambda)$ denote their corresponding density distributions. The integration limits $B$ and $Q$ are determined by the normalization condition

$$n_B = \int_{-B}^{B} \sigma (\Lambda) d\Lambda,$$

$$n = \int_{-Q}^{Q} \rho (k) dk.$$  \tag{15}

The ground state energy per atom is written in our notation as

$$\varepsilon_{\text{hom}} (n_B, n_F, g) = \frac{1}{n} \int_{-Q}^{Q} \frac{\hbar^2 k^2}{2m} \rho (k) dk.$$  \tag{16}

For convenience, let us define the fraction of Bosons $\alpha = n_B/n$ and the dimensionless Lieb-Liniger parameter $\gamma = mg/ (\hbar^2 n)$. We then introduce variables $x = k/Q$ and $y = \Lambda/B$ such that $\rho (k) = \rho (xQ) = g_c (x)$ and

$$\sigma (\Lambda) = \sigma (yB) = g_s (y),$$

and (14)-(16) are transformed into

$$g_c (x) = \frac{1}{2\pi} \left[ 1 + \frac{1}{\lambda_s} \int_{-1}^{1} \frac{g_s (y) dy}{1/4 + (y/\lambda_s - x/\lambda_c)^2} \right],$$

$$g_s (y) = \frac{1}{2\pi} \int_{-1}^{1} \frac{g_c (x) dx}{1/4 + (y/\lambda_s - x/\lambda_c)^2},$$  \tag{17}

with

$$\lambda_c = \gamma \int_{-1}^{1} g_c (x) dx,$$

$$\lambda_s = \frac{\gamma}{\alpha} \int_{-1}^{1} g_s (y) dy,$$  \tag{18}

and

$$\varepsilon_{\text{hom}} (n, \gamma, \alpha) = \frac{\hbar^2 n^2}{2m} \varepsilon (\gamma, \alpha).$$  \tag{19}

Here the function

$$\varepsilon (\gamma, \alpha) = \frac{\gamma^3}{\lambda_c} \int_{-1}^{1} x^2 g_c (x) dx$$  \tag{20}

can be solved numerically with the combination of (17) and (18) by the iteration method. In the limiting cases of $\alpha = 0, 1$, the system is purely fermions or purely bosons. $\varepsilon (\gamma, 0) = \pi^2/3$ is a constant while $\varepsilon (\gamma, 1)$ coincides with $\varepsilon_{\text{Lin-Lin}} (\gamma)$ in the Lieb-Liniger model [42]. When the interaction is weak, $\gamma \ll 1$, the mean field result of (19) is already available in [16, 19]; when the interaction is strong, $\gamma \gg 1$, one can neglect the dependence of the first integrand in (17) on $x$ and $g_c (x)$ can be approximated as a constant $g_c$. Therefore we get the asymptotic behavior of the function $e (\gamma, \alpha)$ for $\gamma$

$$e (\gamma \to 0, \alpha) = \frac{\pi^2}{3} (1 - \alpha)^3 + (2\alpha - \alpha^2) \gamma,$$

$$e (\gamma \to +\infty, \alpha) = \frac{\pi^2}{3} (1 - 4F (\alpha)/\gamma + 12F^2 (\alpha)/\gamma^2)$$  \tag{21}

where $F (\alpha) = \alpha + \sin (\alpha \pi)/\pi$. In the limiting case of $\gamma = 0$, $e (0, \alpha) = \pi^2 (1 - \alpha)^3/3$, therefore $\varepsilon_{\text{hom}} (n, 0, \alpha) = \hbar^2 \pi^2 n_F^2/6mn = \kappa_{\text{hom}}$, the energy comes solely from the kinetic energy of free fermions. In the Tonks-Girardeau limit, $e (+\infty, \alpha) = \pi^2/3$, which means the energy of Bose-Fermi mixture with infinitely strong repulsive interactions is equal to the energy of all atoms treated as free fermions.

For practical use, we need calculate $e (\gamma, \alpha)$ for a lot of points $(\gamma, \alpha)$. If we use numeric iteration method for every point, it will be very time-consuming. To avoid this, we managed to retrieve a parametization formula for $e (\gamma, \alpha)$ based on the above limiting cases, which reads as

$$\tilde{e} (\gamma, \alpha) = \frac{\pi^2}{3} (1 - \alpha)^3 \left[ f_1 (\gamma) (1 + f_2 (\gamma) (1 - \alpha)^2 - (1 + f_2 (\gamma)) (1 - \alpha)^3) \right].$$  \tag{22}
Here $f_1 (\gamma)$ is the approximation of $\epsilon_{L-L}(\gamma)$. We give

$$f_1 (\gamma) = \frac{\pi^2}{3} \gamma^3 + a_2 \gamma^2 + a_1 \gamma$$

(23)

with $b_1 = 11.37$, $b_2 = 4.68$, $a_1 = 12 + b_1 - 4b_2$, $a_2 = -4 + b_2$ and $b_0 = \pi^2 a_1 / 3$, which exhibits the same asymptotic behavior as $\epsilon_{L-L}(\gamma)$ in the weak and strong interaction cases to the order of $\gamma$ and $1/\gamma^2$, respectively. The function $f_2 (\gamma)$ is determined by the numerical iteration result for some sampled values of $\gamma$, and we fit it as

$$f_2 (\gamma) = c_0 \exp (c_1 \gamma) - (c_0 + 1) \exp (c_2 \gamma)$$

(24)

with $c_0 = 0.21$, $c_1 = -0.02$, $c_2 = -1.45$. $\epsilon (\gamma, \alpha)$ gives the exact behavior at the limits $\alpha = 0$, $\gamma = 0$, $+\infty$ and approximates to $\epsilon_{L-L}(\gamma)$ at the limit $\alpha = 1$. In intermediate value of $\alpha$ and $\gamma$, $\epsilon (\gamma, \alpha)$ deviates with a maximum relative error of 0.03 from the numerical result at $\gamma \approx 2.5$, $\alpha \approx 0.9$. In Fig. 1, we exhibit the result of exact numerical result of $\epsilon (\gamma, \alpha)$ compared with the fitting formulas $\epsilon (\gamma, \alpha)$ for various interaction strength $\gamma$ and the fraction of Bosons $\alpha$. Clearly the fitting formulas represent quite well the Betha-Ansatz result for the whole range of interaction and arbitrary fraction of bosonic atoms in the mixture. These formulas are then adopted in the following solution of the KSEs equations.

From $\epsilon_{\text{hom}} (n, \alpha, \gamma)$, the ground state Bose and Fermi chemical potentials can be obtained as

$$\mu_{B, \text{hom}} (n, \alpha, \gamma) = \frac{\hbar^2 n^2}{2m} f_B (\gamma, \alpha),$$

$$\mu_{F, \text{hom}} (n, \alpha, \gamma) = \frac{\hbar^2 n^2}{2m} f_F (\gamma, \alpha),$$

(25)

where

$$f_B (\gamma, \alpha) = 3e - \gamma \frac{\partial e}{\partial \gamma} + (1 - \alpha) \frac{\partial e}{\partial \alpha},$$

$$f_F (\gamma, \alpha) = 3e - \gamma \frac{\partial e}{\partial \gamma} - \alpha \frac{\partial e}{\partial \alpha},$$

(26)

with $f_B (0, \alpha) = 0$, $f_B (0, \alpha) = \pi^2 (1 - \alpha)^2$, and $f_B (+\infty, \alpha) = f_F (+\infty, \alpha) = \pi^2$.

III. NUMERICAL RESULTS

Inserting (25) into the KSEs (9) and (10), and assuming Bosons and Fermions suffer from the same harmonic external potentials $V_B (x) = V_F (x) = m \omega^2 x^2 / 2$, with $\omega$ is frequency, we can get the ground state density profiles of each component by solving the KSEs together with the constraint (3) by means of numerical iteration. The ground state energy follows immediately from (11). Here we introduce the length unit $a = \sqrt{\hbar / m \omega}$ and a dimensionless interacting parameter $U = g / a \hbar \omega$ such that the space dependent Lieb-Liniger parameter is expressed as $\gamma(x) = U / an(x)$. Before going into the details of the DFT result, we first discuss the KSEs for some limiting cases.

When there is no interactions in the mixture, $U = 0$, KSEs correctly reduce to the equations for noninteracting Bosons and noninteracting Fermions in the harmonic trap. The densities of bosonic and fermionic components are respectively

$$n_B (x) = \frac{N_B}{a \sqrt{\pi}} \exp \left( - \frac{x^2}{a^2} \right),$$

(27)

$$n_F (x) = \frac{1}{a \sqrt{\pi}} \exp \left( - \frac{x^2}{a^2} \right) \sum_{l=0}^{N_F-1} \frac{H_l^2 (x/a)}{2^l l!},$$

(28)

where $H_l (x/a)$ is the Hermite polynomials. Here the noninteracting Bose density profile (see the topmost black line in Fig. 2) is a standard Gaussian-like shape and Fermi density profile (see the red dotted line in Fig. 2) is characterized by a half ellipse-like shape with $N_F$ oscillations.
The ground state energies of these two components are

$$ E_{0B} = \frac{N_B}{2} \hbar \omega, $$

$$ E_{0F} = \sum_{l=0}^{N_F-1} \left( l + \frac{1}{2} \right) \hbar \omega $$

and the total ground state energy is $E_0 = E_{0B} + E_{0F}$.

When the interaction is weak, neglecting $E_{xc}$ in (2), the KSEs reduce to our familiar mean-field formulas

$$ -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \frac{1}{2} m \omega^2 x^2 + g (n_B + n_F) \phi = \epsilon \phi, $$

$$ -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \frac{1}{2} m \omega^2 x^2 + g n_B \psi_j = n_j \psi_j. $$

For bosons it is nothing but the Gross-Pitaevskii equation for dilute gas. The equation for fermions, on the other hand, reminds us the superfluid theory of the mixture of bosons and paired BCS states of the two-component fermions where only one Fermionic orbital is considered.

When the interaction is strong, for system of large atom numbers $N_B, N_F \gg 1$, one can safely use the Thomas-Fermi approximation (TFA), i.e., the kinetic energies $T^{ref}_B$ and $T^{ref}_F$ in the energy functional (2) are approximated to zero and $\int n(x) \kappa_s^{hom}(x) \, dx$, respectively. Minimizing $E_0$ directly with respect to $n_B(x)$ and $n_F(x)$, we get the TFA formulas

$$ \frac{1}{2} m \omega^2 x^2 + \mu^{hom}_B \langle n_B, n_F; x \rangle = \mu^0_B, $$

$$ \frac{1}{2} m \omega^2 x^2 + \mu^{hom}_F \langle n_B, n_F; x \rangle = \mu^0_F, $$

where $\mu^0_B$ and $\mu^0_F$ are constants fixed by the normalization conditions $\int n_B(x) \, dx = \text{N}_B$ and $\int n_F(x) \, dx = \text{N}_F$. Eqs. (32) are explained as the LDA of the chemical potentials at point $x$ in (19) and have been used extensively. That means, in slowly varying external harmonic trap chemical potentials at point $x$ are related to those in the trap center $x = 0$ ($\mu^0_B$ and $\mu^0_F$).

When repulsive interactions are infinitely strong, $\mu^{hom}_B = \mu^{hom}_F = h^2 \pi^2 n^2/2m$, (32) reduces to a single equation

$$ \frac{1}{2} m \omega^2 x^2 + \frac{h^2 \pi^2}{2m} n(x) = \mu^0, $$

with $\mu^0$ is decided by $\int n(x) \, dx = N$. This gives us the explicit result for total density distribution

$$ n(x) = \sqrt{\frac{2N - x^2/a^2}{\pi a}}, $$

and ground state energy

$$ E_0 = \frac{\text{N}^2}{2} \hbar \omega. $$
We see that they are exactly the density distribution and energy of \( N \) free fermions in a harmonic trap. Equation \( \text{Eq.} \), however, gives nothing about the densities of Bose and Fermi components. The method here is insufficient for the infinitely strong interaction. We may, on the other hand, resort to the Bose-Fermi mapping method \([23, 24]\) which gives the Bose and Fermi density profiles as

\[
n_{B,F}(x) = \frac{N_{B,F}}{N\sqrt{\pi}} \exp\left(-x^2/\alpha^2\right) \sum_{n=0}^{N-1} \frac{H_n^2(x)}{2^n n!}.
\]

The two components are nondemixing in agreement with the generalized Bethe ansatz wave function \([22]\).

The DFT results are summarized in Figs. 2-8. First, for a pure bosonic system, equation \( \text{Eq.} \) is just the generalized Gross-Pitaevskii equation appeared in Refs. \([31, 32]\). We show the density profiles for \( N_B = 10 \) bosons in Fig. \( \text{Fig.} \) for the cases of \( U = 0, 0.1, 0.5, 1, 5, 10 \) and \( +\infty \), respectively. With the increasing of \( U \), the density profiles vary from a standard Gaussian-like to a non-oscillating half-ellipse shape. Comparing the density profiles of Bosons at \( U = +\infty \) and the noninteracting fermions, we find that they match each other quite well except the density oscillations. The results mean the density distribution of Bosons with infinitely strong repulsive delta interaction is basically the same as that of a noninteracting Fermi gas which is consistent with the theory of Bose-Fermi mapping theory \([24]\). Our theory fails to reproduce the density oscillation due to the impenetrable property of 1D system with strong interaction because we adopt one single functional orbital \( \phi(x) \) for the 1D Bose liquid. The exact oscillations reflecting the structure of the occupied orbitals should be quested from the real wave function such as by the exact diagonalization method \([15]\). In the limit of large particle number the differences between the oscillating and non-oscillating profiles become imperceptible.

The ground state energy evolution as a function of \( U \) is illustrated in Fig. \( \text{Fig.} \). We can see that with the increase of \( U \), the kinetic energy \( T^{\text{eff}} \) decreases slowly indicating that the interaction restrains the movement of atoms. The external potential energy \( E_{\text{pot}} \) increases as a result of wider and wider occupied regime of the trap. Both of these two energies evolve to constant energies. The Hartree-Fock energy \( E_{HF} \) increases almost linearly while the exchange correlation energy \( E_{xc} \) decreases in the whole interaction regime. These two terms play more and more important roles in the DFT theory for stronger interaction and they approximately cancel each other. All these energies contribute to the total energy \( E_0 \), which starting from the noninteracting value \( 5\hbar \omega \) approaches the strongly interacting limit \( 50\hbar \omega \). For \( U < 0.9 \), the exchange correlation energy is much less than the total energy, \( E_{xc}/E_0 < 0.1 \), which can be seen as the effective regime of mean field theory. For a TG gas with \( U = +\infty \) and a chemical potential \( \mu_B^{\text{hom}} = \hbar^2 \pi^2 n^2 / 2m \), numerically solving equation \( \text{Eq.} \) gives \( E_0 = 50.5024 \hbar \omega \) which lies slightly above \( 50\hbar \omega \) because the introduced Bose functional orbital \( \phi(x) \) is only an assistant variational function instead of the true wave function of the interacting Bose system.

We now turn to illustrate the main result of a mixture of \( N_B = 10 \) bosons and \( N_F = 10 \) fermions. The densities of non-interacting mixture \([27, 28]\) are taken as the starting point of the iteration of KSEs \([27]\) for a small interaction parameter (e.g. \( U = 0.1 \)). The eigenvalues

\[
\begin{align*}
\text{Fig. 4: (Color Online) Density distributions of a mixture of } N_B = 10 \text{ bosons and } N_F = 10 \text{ fermions for different interaction parameter } U = 0.1, 1, 5 \text{ (left) and } U = 20, 100, +\infty \text{ (right).}
\end{align*}
\]

\[
\begin{align*}
\text{Fig. 5: (Color Online) The total density profiles } n \text{ as a function of } x \text{ for a } N_B = N_F = 10 \text{ mixture with } U = +\infty \text{. The result of KSEs (black solid line), TFA (blue dashed line) and Bose-Fermi Mapping (red dotted line) are compared and the inset shows a zoom into the structure of the oscillations.}
\end{align*}
\]
\[ \epsilon_j \] and functional orbitals \( \phi, \psi_j \) are found by iterating to the desired degree of accuracy. The new densities are initial densities for the next iteration for a larger interaction parameter, and so on. The density profiles for different \( U \) are displayed in Fig. 3. It shows that with increasing \( U \), the peak of the total density \( n(x) \) decreases monotonically and atoms tend to occupy wider regime. The density of Fermi component changes smoothly in amplitude, while Bose component becomes more and more flat and ripples begin to appear for stronger interaction. At weak interaction, \( U = 0.1, 1 \) as in Fig. 3(a) and (b), both Bosons and Fermions are located in the center of the trap. For an intermediate interaction strength, e.g. \( U = 5 \) as in Fig. 3(c), some fermions are excluded from the center of the trap while Bosons are held mainly in the center. We notice that oscillations emerge in the Bose density curves reflecting the strong correlation with Fermions. When \( U \) becomes further stronger, \( U = 20, 100 \) as in Fig. 3(d) and (e), more Fermions are repelled out from the center and a clear signature of phase separation of bosons and fermions is seen in the figures. High density of discrete bosons are surrounded by fermions, which nevertheless still have chance to squeeze between the opening space of bosons. The total density profile approaches half ellipse-like for \( U = +\infty \) as shown in Fig. 3(f). We may have a close inspection of the case of infinitely strong interaction. In Fig. 4, the DFT result of the total density is compared with those from TFA and Bose-Fermi mapping. It is clear that the agreement is fairly good except tiny difference in the number, position and amplitude of the oscillations which are enlarged in the inset of Fig. 4. Again for large atom number the differences between the oscillating and non-oscillating curves is unperceivable.

\[ \epsilon_j, \eta_j \] and functional orbitals \( \phi, \psi_j \) are found by iterating to the desired degree of accuracy. The new densities are initial densities for the next iteration for a larger interaction parameter, and so on. The density profiles for different \( U \) are displayed in Fig. 3. It shows that with increasing \( U \), the peak of the total density \( n(x) \) decreases monotonically and atoms tend to occupy wider regime. The density of Fermi component changes smoothly in amplitude, while Bose component becomes more and more flat and ripples begin to appear for stronger interaction. At weak interaction, \( U = 0.1, 1 \) as in Fig. 3(a) and (b), both Bosons and Fermions are located in the center of the trap. When \( U \) becomes further stronger, \( U = 20, 100 \) as in Fig. 3(d) and (e), more Fermions are repelled out from the center and a clear signature of phase separation of bosons and fermions is seen in the figures. High density of discrete bosons are surrounded by fermions, which nevertheless still have chance to squeeze between the opening space of bosons. The total density profile approaches half ellipse-like for \( U = +\infty \) as shown in Fig. 3(f). We may have a close inspection of the case of infinitely strong interaction. In Fig. 4, the DFT result of the total density is compared with those from TFA and Bose-Fermi mapping. It is clear that the agreement is fairly good except tiny difference in the number, position and amplitude of the oscillations which are enlarged in the inset of Fig. 4. Again for large atom number the differences between the oscillating and non-oscillating curves is unperceivable.
wave function is essentially replaced by a Slater determinant of single-particle Schrödinger equation in the trap potential, to give a nondemixing result at finite large interactions. They further tested this nondemixing result with numerical DMRG simulations for a lattice model of $N_B = N_F = 2$ mixture [27]. We observe, however, obvious signature of phase separation in Fig. 4 of [27] for relatively large interaction $U = 100$. The intrinsic nature of the phase separation and nondemixing in TG limit originates from the Bethe ansatz and Bose-Fermi mapping techniques respectively. We expect experimental verification of the nature of spatial configuration about trapped ultracold atomic mixtures.

Finally we discuss the effect of another system parameter, i.e. mean value of the fraction of bosonic atoms number $\bar{\alpha} = N_B/N$, on the density profiles. Fig. 7 shows the density of each component and the total density of $N = 20$ atoms in the mixture with $\bar{\alpha} = 0.25, 0.75$ and interaction parameters $U = 1, 10$. Fig. 5 compares their energies. Bosons will dominate the total density profile when more bosons are put into the mixture for weak as well as strong interaction. When more fermions are prepared in the gas, bimodal distribution is clearly seen the total density where bosonic Gaussian shape is superimposed onto the fermionic shell-like structure. In the strong interaction limit the total density approaches to the typical half-ellipse no matter how many bosons or fermions are involved in the mixture. The number of fermions contribute to the ground state energy more effectively in the weak interaction case. This situation changes for strong interaction where the energies for all values of $\bar{\alpha}$ approximate to the limit value of the fully fermionization of the system.

\section{IV. Conclusion}

In conclusion, using the DFT we study the ground state energy and density distribution of the Bose-Fermi mixture in a quasi 1D harmonic trap. Based on the Bethe ansatz solution for the mixture, we managed to obtain a fitting formula for the function $e(\gamma, \alpha)$ for the ground state energy of homogeneous system. The KSEs are obtained from the variational minimization of the energy functional of trapped mixture with respect to the densities of bose and fermi components. We found that when the interaction between the atoms varies from zero to positive infinity, the ground state energy of the mixture would evolve to the constants of the noninteracting Fermions and the total density approached a half ellipse profile. More and more fermions are expelled out of the trap center, while bosons occupy the central region. Phase separation of boson and fermion components occurs for strong interaction in agreement with the the result Bethe ansatz method plus LDA. The calculation here applies equally to the pure bosonic case, different fraction of bosons, as well as in the TG limit. Our DFT theory is also suitable for mixtures in optical lattice and could be extended to study the dynamical and thermodynamic phenomena of the mixture.
