NO-synthesis/arginasins System in Plasma and Blood Lymphocytes in Women with Primary Infertility and Recurrent Pregnancy Loss with Ascariasis Presence

Valentyna Sklyarova, Rostyslav Chajkivskyy, and Pavlo Sklyarov

Abstract—

Materials and methods: This is an investigation of 49 cases with confirmed ascariasis and pathology of reproductive system in the Lviv City Center for Family Planning and Human Reproduction Lviv Ukraine between January 2013 and December 2015.

Purpose: The aim of the study was to investigate changes in the L-arginine / NO synthase / arginase system in women with primary infertility and recurrent pregnancy loss with ascariasis presence in Ukraine.

Results: In women with recurrent pregnancy loss and women with primary infertility were observed significant activation of iNOS in lymphocyte lysates, an increase in nitrite anion production, and a decrease in L-arginine content in the blood plasma and ascariasis compared with RPL and PI patients without ascariasis.

Conclusion: Ascariasis can be factor of the development of inflammation.

Index Terms— NO; Ascariasis; Infertility; Recurrent Pregnancy Loss.

I. INTRODUCTION

The L-arginine/ NO synthase/arginase system is key in the functioning of endothelial cells and is involved in the regulation of numerous processes in the body, including mechanisms of reproduction [13]. L-arginine is an essential amino acid necessary for spermatogenesis, embryonic and fetal development, growth and development of the fetus, as well as maintaining vascular tone and hemodynamics [4]. NO synthesized from L-arginine may be involved in follicular maturation and ovulation, as well as in the regulation of ovarian vessel tone and endometrium [1]. That is, the balance between the content of L-arginine in the blood plasma and the production of nitrogen oxide by endothelial cells is one of the factors involved in supporting the reproduction processes [15]. Blood lymphocytes maintain the immunological status of the organism due to their phagocytic activity, synthesis of pro- and anti-inflammatory cytokines and NO secretion [2], [11], [12]. It has been noted that the activity of NO synthase and arginase in peripheral blood lymphocytes changes in conditions of autoimmune diseases in humans [5], and the concentration of L-arginine in blood plasma is significantly reduced upon infection and inflammation [3]. Ascariasis is one of the most common human parasitic infections in the world [6]. The persistence of ascarid eggs in the lower parts of the female reproductive system, as well as the presence of parasites there, can cause various local disorders, as well as affect the state of vascular endothelial cells, NO synthase / arginase, the activity of liperoxidation processes in lymphocytes and blood plasma [7].

The aim of the study was to investigate changes in the L-arginine / NO synthase / arginase system in women with primary infertility and recurrent pregnancy loss with ascariasis presence in Ukraine.

II. MATERIALS AND METHODS

The studies performed in Lviv City Center for Family Planning and Human Reproduction, the Departments of Family Medicine and Clinical Affairs and Biochemistry of Danylo Halytsky National Medical University, Lviv, Ukraine. We examined 53 patients with recurrent pregnancy loss (RPL), including 28 women without ascariasis (A) (subgroup L) and 25 women with ascariasis (subgroup K), and 51 patients with primary infertility (PI): 27 women without ascariasis (subgroup P) and 24 women with presence of acarida invasions (subgroup S). Control group consistent 24 gynecological and somatically healthy women without pathology of reproduction. Biochemical research methods have included the determination of relevant targets in blood plasma and lymphocyte lysates.

The activity of NO synthases in lymphocyte lysates was determined according to the method of VV Sumbayev [8].

For the determination of antibodies to parasites (Toxocara canis, Giardia lamblia and Ascaris lumbricoides), kits of Vitrotest Anti (Ramintech, Ukraine) were used.

Parasitological examination included coproscopy and enterobiosis examination. Each stool sample was developed using the methods of Kato, Füleborn, and Schulman [17]. Enterobiosis examination was performed using the adhesive tape method (according to Graham) and the method of perianal scraping (according to Torgushin) [18].

Statistical processing of results was performed using SPSS 7.0 and Microsoft Excel 2000. A literature review was conducted.

### III. RESULTS

In plasma of healthy women the concentration of nitrogen oxide was 21.2 ± 1.4 μmol/l, the total content of nitrate and nitrite of anions was - 23.2 ± 1.9 μmol/l, arginase activity was within the normal range (Tables 1, 2).

**TABLE 1 - CHANGES IN ARGINASE ACTIVITY, NITRITE ANION CONTENT AND BLOOD PLASMA L-ARGININE CONCENTRATIONS IN WOMEN WITH RECURRENT PREGNANCY LOSS AND PRIMARY INFERTILITY AND ASCARIASIS (M ± M)**

| Examined groups | Arginase μmol/min·ml | L-arginine μg/ml | Nitrite anion μmol/l |
|-----------------|----------------------|----------------|-------------------|
| Control group (n = 24) | 0.28±0.05 | 25.1±6.3 | 14.8±0.9 |
| Subgroup P (n = 27) | 0.25±0.08 | 24.7±7.8 | 17.2±1.8 |
| Subgroup S (n = 24) | 0.23±0.05 | 21.4±3.1 | 20.6±0.4** |
| Subgroup L (n = 28) | 0.27±0.08 | 24.1±1.6 | 15.4±1.3 |
| Subgroup K (n = 25) | 0.22±0.05 | 20.7±2.9 | 21.2±0.7* |

Note 1. * - a significant difference (p <0.05) between the female subgroup K (RPL and A) and the control group.
Note 2. ^ is a significant difference (p <0.05) between the female subgroup S (RPL and A) and the subgroup P (non A).
Note 3. # is the difference (p <0.05) between the female subgroup K (RPL and A) and the subgroup L (non-A).

The concentration of L-arginine, a precursor for NO synthase and arginase in the blood of control women, was significantly higher (3.4-fold, p <0.01) than in lymphocyte lysates.

The ratio between the plasma L-arginine concentration and the lymphocyte lysate in the blood of control women was 3.37. The sharp gradient between plasma L-arginine concentration and lysate indicates the high level of amino acid utilization and its need for lymphocyte metabolism.

Nitrite-anion content in blood plasma exceeded its concentration in lymphocyte lysate by 70% (p <0.05). Arginase activity was slightly higher in lymphocyte lysates.

Therefore, the content of nitrite anion in the blood plasma and in the lymphocyte lysate is due to its synthesis from L-arginine eNOS localized in vascular endothelial cells and lymphocytes. The ratio of nitrite anion content in blood plasma and lysate was 1.43. Plasma arginase activity and lymphocyte lysate were not significantly different in healthy women.

The results of studies show that the state of NO synthase system in nonpregnant healthy women were characterized by the dominance of the activity of eNOS in lymphocytes, due to the absence in the blood of factors that activate iNOS, primarily microbial lipopolysaccharides, pro-inflammatory cytokines and hypoxia. iNOS activity in lymphocyte lysates was low (Table 2).

The activity of arginase did not change, and the concentration of L-arginine in the blood plasma decreased by 69% (p <0.05), and in the lymphocyte lysate remained unchanged.

**TABLE 2 - CHANGES IN ARGINASE ACTIVITY, NITRITE ANION CONTENT AND L-ARGININE CONCENTRATION IN LYMPHOCYTE LYSATES IN WOMEN WITH RECURRENT PREGNANCY LOSS AND PRIMARY INFERTILITY AND ASCARIASIS (M ± M)**

**Examined groups** | Arginase μmol/min·ml | L-arginine μg/ml | Nitrite anion μmol/l |
|---------------------|----------------------|----------------|-------------------|
| Control group (n = 24) | 0.20±0.06 | 84.6±7.2 | 21.2±1.4 |
| Subgroup P (n = 27) | 0.21±0.04 | 79.4±5.5 | 23.6±1.4 |
| Subgroup S (n = 24) | 0.18±0.05 | 61.2±5.2** | 26.8±0.5** |
| Subgroup L (n = 28) | 0.22±0.05 | 80.8±5.3 | 23.5±0.8 |
| Subgroup K (n = 25) | 0.19±0.04 | 67.7±5.8** | 25.9±0.8** |

Note 1. * - a significant difference (p <0.05) between the S (RPL and A) women and the control group.
Note 2. ^ is a significant difference (p <0.05) between the female subgroup S (RPL and A) and the subgroup P (non A).
Note 3. # is the difference (p <0.05) between the female subgroup K (RPL and A) and the subgroup L (non-A).

This indicates that the concentration of L-arginine in the cytoplasm of lymphocytes is maintained at a stable level and with the increase of eNOS activity increases the supply of L-arginine from the blood plasma (Table 3).

In women with RPL without ascarida invasion, the indicators of L-arginine content, anion nitrite, and arginase activity were not significantly different from those of control women. However, women in this group in lymphocyte lysate increased eNOS activity by 58% (p <0.05), compared with healthy subjects. The activity of iNOS and arginase did not change significantly. In women with PI without ascaridia, NO-synthase activity rates were at the level of data in patients with RPL.

**Table 3 - CHANGES IN THE ACTIVITY OF NO SYNTHASES IN LYMPHOCYTE LYSATE IN WOMEN WITH RECURRENT PREGNANCY LOSS AND PRIMARY INFERTILITY AND ASCARIASIS (M ± m)**

| Examined groups | NO synthase nmol/min·ml | iNOS nmol/min·ml | eNOS nmol/min·ml |
|-----------------|-------------------------|----------------|-----------------|
| Control group (n = 24) | 0.76±0.17 | 0.08±0.01 | 0.07±0.18 |
| Subgroup P (n = 27) | 1.15±0.27 | 0.07±0.02 | 1.06±0.25 |
| Subgroup S (n = 24) | 1.20±0.09* | 0.78±0.08** | 0.42±0.15 |
| Subgroup L (n = 28) | 1.22±0.3* | 0.08±0.02 | 1.13±0.18 |
| Subgroup K (n = 25) | 1.21±0.17* | 0.68±0.07* | 0.53±0.13 |

Note 1. * - a significant difference (p <0.05) between the S (RPL and A) women and the control group.
Note 2. ^ is a significant difference (p <0.05) between the female subgroup S (RPL and A) and the subgroup P (non A).
Note 3. # is the difference (p <0.05) between the female subgroup K (RPL and A) and the subgroup L (non-A).

In women with primary infertility and ascarida invasion, plasma nitrite anion content increased by 14% (p <0.05) and L-arginine concentration decreased by 20% (p <0.05). At the same time, the lymphocyte lysate also increased the content of nitrite anion (by 20%, p <0.05), there was a tendency to decrease L-arginine and sharply increased the activity of iNOS (p <0.01) and decreased the activity of eNOS (p < 0.05). Women with PI and ascaris showed a 28% increase in nitrite anion content (p <0.05), 8.5-fold increase in iNOS activity (p <0.01).

The results obtained indicate that the presence of ascarida in women with primary infertility or with recurrent pregnancy loss causes a pro-inflammatory systemic reaction, which is manifested in an increase in nitrite-anion production due to increased activity of iNOS. secretory excretory products produced by ascarids are active substances that can directly or with the participation of pro-inflammatory cytokines activate iNOS of endothelial cells and lymphocytes. These processes are particularly dangerous in small vessels and capillaries of the uterus and...
