ABSTRACT

Background: Epidermal inclusion cyst, smegma stones and urethral calculi of the penis are rare and may result as a late complication of hypospadias repair. This study reported the presentation and management of these late complications.

Methods: A prospective observational study included male patients aged more than 6 years of age, who had undergone hypospadias repair 3-15 years back and presented with slow growing, non-tender, mobile, firm to hard swelling. Histopathological and radiographic examination were done and surgery was used for management of epidermal inclusion cyst, urethral calculi and smegma stone. Patients were followed up for one year, postoperatively.

Results: Out of 15 patients, two (13.3%), four (26.7%) and nine (60%) patients were diagnosed with smegma stones, epidermal inclusion cyst and urethral calculi, respectively. The median (range) age of patients was 17 (8-30) years. Patients were presented with slow growing, non-tender, mobile swelling measuring from 1 cm x 3 cm to 2 cm x 1.5 cm. The average size of epidermal inclusion cyst, and urethral calculi was 2 cm x 2.5 cm x 1.5 cm, and 2 cm x 3 cm, respectively. Treatment were complete excision of cyst and removal of smegma stones by surgery and urethral calculi by dorsal urethrotomy. All patients had an uneventful postoperative period and were asymptomatic up to one year of follow-up.

Conclusion: Results suggest that these complications can be managed with complete excision and surgical removal and care must be taken while performing the hypospadias repair to avoid these unusual late complications in patients.

Keywords: Epidermal inclusion cyst, penile swelling, smegma stone, urethral calculi

INTRODUCTION

Epidermal inclusion cyst or epidermoid cyst is a cutaneous lesion which develops out of the ectodermal tissue and can develop on any part of the body. However, the penile localization of this cyst is very rare.1-3

Epidermal inclusion cyst is mostly reported as a congenital or idiopathic finding diagnosed during childhood but there are very limited reports of development of epidermal inclusion cyst as a complication of hypospadias repair.
Additionally, smegma stones and urethral calculi are uncommon complications of hypospadias repair. These occur either by rolling in the epidermis at the time of hypospadias surgery or possibly by implantation of smegma in the surgical wound. The urethral diverticulum may cause stasis of urine, and infection leading to the development of urethral calculi.4,5

The present study aimed to report the presentation and management of uncommon late complications (smegma stones, urethral calculi and epidermal inclusion cyst) of hypospadias repair in patients with history of hypospadias repair.

METHODS

A prospective observational study was conducted in the Department of Surgery, Dr. S. N. Medical College, Jodhpur, Rajasthan, India between December 2016 and December 2018.

All male patients aged more than 6 years of age, who had undergone hypospadias repair 3-15 years back, with slow growing, non-tender, mobile, firm to hard swelling measuring from 1 cm x 3 cm to 2 cm x 1.5 cm size were included in the study. Histopathological examination was carried out for diagnosis of epidermal inclusion cyst. Urethral calculi and smegma stone of distal penile shaft were diagnosed with radiographic examination. Epidermal inclusion cyst and smegma stone were removed with surgery while urethral stones were removed with dorsal urethrotomy. Patients were followed up for one year, postoperatively.

RESULTS

Total of 15 male patients who had undergone hypospadias repair 3-15 years back and presented with slow growing, non-tender, mobile, firm to hard swelling measuring from 1 cm x 3 cm to 2 cm x 1.5 cm size were included in the study. The median (range) age of patients was 17 (8-30) years (Table 1).

Table 1: Baseline characteristics of patients with hypospadias repair.

| Patient’s characteristics | N=15 |
|---------------------------|------|
| Median age in years (range) | 17 (8-30) |
| Diagnosis of complications | Histopathological examination |
| Epidermal inclusion cyst | Radiographic examination |
| Smegma stones | Radiographic examination |
| Urethral calculi | |
| Range of size of swelling (cm) | (1 cm x 3 cm) - (2 cm x 1.5 cm) |

Out of 15 patients, four (26.7%) patients had one-year history of oval shape swelling in the penile skin at the dorsolateral aspect of left side just proximal to corona-glandis along the hypospadias scar (Figure 1).

Complications of hypospadias repair

| Percentage of patients |
|-----------------------|
| Urethral calculi | 60 |
| Epidermal inclusion cyst | 26.7 |
| Smegma stones | 13.3 |

Figure 1: Complications in patients with hypospadias repair.

Figure 2. A representative photo of patient present with cystic swelling of penis distal shaft of penis

Figure 3. Operative photo: (A and B) excision of epidermal cyst, (C) repair of surgical wound with Vicryl 4-0 suture and (D) pathological specimen of epidermal inclusion cyst.

They had painless slow growing penile swelling. Clinical and physical examination showed non-tender, mobile
swelling of average size of 2 cm x 2.5 cm x 1.5 cm (Figure 2). Surgical excision of the swellings was performed which were provisionally diagnosed as epidermal inclusion cysts. Histopathological examination of the excised cysts confirmed diagnosis of epidermal inclusion cyst (Figure 3A-D).

Other nine (60%) patients had a history of splaying and weak urinary stream, gradually increasing painless penile swelling at the distal part of the penile shaft (Figure 1). They had undergone repair of congenital mid penile hypospadias 5-15 years back. Clinical and physical examination showed hard penile lumps, average 2 cm x 3 cm in size, non-tender, mobile swelling on the ventral aspect of distict part of the penis (Figure 4A). Radiographic examination showed two radio-opaque shadows in the distal part of the penis and were diagnosed as urethral calculi. These patients underwent dorsal urethrotomy for the removal of urethral calculi with hairs (Figure 4B-D).

Remaing two (13.3%) patients were presented with gradual increasing painless, non-tender swelling of distal penile ((Figure 1; Figure 5A-C) and had history of repair of congenital hypospadias. Radiographic examination reported diagnosis of smegma stone of distal penile shaft and were surgically removed.

All patients had an uneventful postoperative period. Patients were discharged from hospital after first dressing between second to fifth postoperative day. All were asymptomatic up to one year of follow-up. Passage of urine in good stream and wounds were healthy.

**DISCUSSION**

Epidermal inclusion cyst, smegma stone, and urethral stone are rare and can occur after a minor surgical operation like circumcision or hypospadias repair and penile reconstructive surgery. Several mechanisms have been put forward to explain the development of epidermal inclusion cyst in patients with hypospadias repair. These mechanisms include: implantation and proliferation of epidermal element in the dermis; epidermal tissue could have been implantation during the procedure; sequestration of epidermal rests during embryonic life; occlusion of the pilosebaceous unit, or it could be the result of traumatic implantation of epithelial elements. Clinically, these cysts are generally small, slow growing, soft, freely movable.

In the present study, size of penile swelling was measuring from 1 cm x 3 cm to 2 cm x 1.5 cm. The epidermal cyst generally has no symptoms and patient may seek medical advice only in case of any complications or difficulty in having sexual intercourse. The diagnosis of epidermal inclusion cyst primarily depends on clinical evaluation and ultrasound or computed tomography (CT) examinations.

In the present study, patients had a history of hypospadias repair in the past which could be the causes of inclusion cyst, urethral stone and smegma stone. The diagnosis was confirmed by history, clinical examination, X-ray of penile soft tissues; however, we did not perform the ultrasound or CT examination.

In all these patients, surgical excision and removal is the treatment of choice. There is a rare possibility of malignancy in these patients and the differentiation from congenital swelling of the penis must also be considered. Size of the swelling, the rate of growth, the potential for urethral obstruction, and difficulty in sexual intercourse are indications for surgical excision. In this study, the epidermal inclusion cysts were treated with complete excision. However, urethral calculi and smegma stones were managed by surgically removing these stones. It has
been demonstrated that complete excision, removal and, careful follow-up is enough to manage this type of cases.\textsuperscript{10,11} Other treatment modalities like aspiration or drainage of epidermal inclusion cyst may not be effective and may increase the risk of recurrence.

A previous study by Howe et al. reported their experience of management of 220 adolescents and adults with complications of hypospadias repair during childhood. They concluded that complications of childhood hypospadias repair may present later in life as some urethroplasties deteriorate with time and suggested that parents of children with repaired proximal hypospadias should come for follow-up as their child transitions to adolescence.\textsuperscript{12}

A case report by Giambanco et al. suggested surgical excision of epidermal inclusion cyst after urethroplasty must be performed as quickly as possible to avoid occurrence of postoperative complications.\textsuperscript{13} Another very recent case report by Gular et al. concluded that epidermal inclusion cyst as a complication of hypospadias surgery is a very rare situation and histopathological diagnosis and surgical excision is sufficient for treatment.\textsuperscript{14} The present study results corroborate these findings.

The key limitation of the present study is its very small sample size.

**CONCLUSION**

Epidermal inclusion cyst, smegma stones, and urethral stones are unusual complications of hypospadias repair. Care must be taken while performing hypospadias repair to avoid these complications.
