Abstract
Gestation outside the uterine cavity in which the implantation occurs in any tissue other than the endometrium is referred as ectopic pregnancy. The most place for occurring ectopic pregnancy (97% of cases) is the fallopian tubes including ampulla (55%), isthmus (25%), and fimbria (17%), and in 3% of patients ectopic pregnancy occurs in the abdominal cavity, ovary, or cervix. The tubal twin ectopic pregnancy is a rare condition, and the first unilateral tubal twin was reported by De Ott in 1891, and the first live twin tubal ectopic pregnancy was reported in 1944 [2]. A live tubal twin ectopic pregnancy is a very rare condition and among >100 reports of tubal twin pregnancies, till now, only 8 cases were live [3]. Early diagnosis and treatment of women with tubal twin ectopic pregnancy is very important and may decrease the risk of tubal rupture. I present three cases of tubal twin ectopic gestation. In the first case, spontaneous unilateral live tubal twin ectopic gestation. The second and third cases spontaneous ruptured twin ectopic gestation. All three cases were successfully managed and there was no history of assisted reproductive technique fertilization or pelvic inflammatory disease.

Objective
The above case report was to describe the ultrasonography findings of tubal twin ectopic gestation, to describe various surgical techniques in management of the condition.

Introduction
Gestation outside the uterine cavity in which the implantation occurs in any tissue other than the endometrium is referred as ectopic pregnancy. The most place for occurring ectopic pregnancy (97% of cases) is the fallopian tubes including ampulla (55%), isthmus (25%), and fimbria (17%), and in 3% of patients ectopic pregnancy occurs in the abdominal cavity, ovary, or cervix.[1] The tubal twin ectopic pregnancy is a rare condition, and the first unilateral tubal twin was reported by De Ott in 1891, and the first live twin tubal ectopic pregnancy was reported in 1944 [2]. A live tubal twin ectopic pregnancy is a very rare condition and among >100 reports of tubal twin pregnancies, till now, only 8 cases were live.[3] Early diagnosis and treatment of women with tubal twin ectopic pregnancy is very important and may decrease the risk of tubal rupture. The present report describes a successful management of spontaneous twin tubal ectopic pregnancies with no history of assisted reproductive technique fertilization or pelvic inflammatory disease. Objective of the above case report was to describe the ultrasonography findings of tubal twin ectopic gestation, to describe various surgical techniques in management of the condition.

CASE: 1

Case Presentation
A 35 year old female G2P1L1A0, came to casualty at midnight with pain in abdomen since three days with 8 weeks of amenorrhea and bleeding per vaginum since morning. She had history of two spontaneous abortions. Upon examination, her vitals were stable. Abdomen examination was unremarkable. Upon per vaginum examination the cervical movement was tender, the uterus was bulky and soft, and bogginess and tenderness were felt in the right adnexa. However, her urine pregnancy test was positive. Ultrasonography with doppler study showed a uterus of 8.3x 5.4x 4.2 cms with endometrial thickness of 10 mm and there was evidence of large heterogeneous lesion in the right adnexa of a size 7.1x 5.1 cms, with sac like structure within which two foetal poles measuring 1.4 cm = 7 weeks and five days. Fetal cardiac activity was appreciated. Mild free fluid was seen in the abdomen. An impression of live twin ectopic pregnancy in the right adnexa was made with mild free fluid in an abdomen. A pseudosac like structure was noticed in endometrial cavity. Both ovaries were visualised separately from the right adnexal mass.
In view of the Twin live ectopic pregnancy she was immediately operated. Intraoperatively, the ampullary part of the right fallopian tube was found showed a sac like structure. A right salpingotomy was done. She was discharged on the 7th day. On cut section of the sac there was evidence of two embryos. Pathological evaluation of the surgical specimen showed a diamniotic monochorionic twin’s pregnancy within the fallopian tube and measurement of the twin feti estimated their gestational age at 7 weeks.

**Figure 1:** Shows Right adnexal sac with Twin live ectopic gestation of approximately 7wks 5 days. No intrauterine pregnancy. Both ovaries are separately visualised.

**Figure 2:** Pathological evaluation of the surgical specimen showed a diamniotic monochorionic twins pregnancy.
CASE 2

A 30 year old female, G2L1A0 came to casualty with severe pain in abdomen since two days with 6 weeks of amenorrhea and bleeding per vaginum since morning. She had one living issue with full term normal deliveries. Upon examination, her vitals were stable. Abdomen examination was unremarkable. However, her urine pregnancy test was positive. Spontaneous pregnancy there was no history of induction of ovulation by drugs or artificial reproductive techniques.

The patient was taken for ultrasonography

Transvaginal Sonography showed a heterogeneous mass in right adnexa measuring approximately 7.3 x 4.6 cm. The mass showed irregular Gestational sac measuring approximately 0.3 cm corresponding to 5 weeks and another irregular sac measuring 0.5 cm corresponding to 5 weeks 2 days. Right ovary was visualised separately from this mass.

Left ovary was visualised and appears normal. Moderate hemoperitoneum was seen. Uterus was bulky however there was no intrauterine gestational sac.

The diagnosis of right adnexal ruptured ectopic gestation was made.

Preliminary investigations were done and patient was taken up for laparotomy in view of right adnexal mass and hemoperitoneum.

Per operatively gross morphology was: Right adnexal complex mass with moderate hemoperitoneum. Right salpingostomy was performed. Patient’s post-operative period was uneventful.

Histopathology report came out to be right adnexal two gestational sacs were noted.

CASE 3

A 36 year old female, G3L2A0 came to casualty with severe pain in abdomen since three to four days with 6 weeks of amenorrhea and bleeding per vaginum since morning. Upon examination, her vitals were stable. Abdomen examination was unremarkable. Upon per vaginum examination the cervical movement was tender, the uterus was bulky and soft, and bogginess and tenderness were felt in the both adnexae. However, her urine pregnancy test was positive.

Spontaneous pregnancy there was no history of induction of ovulation by drugs or artificial reproductive techniques.

The patient was taken for ultrasonography

Transvaginal Sonography showed a heterogeneous mass in right adnexa with irregular Gestational sac measuring approximately 1.0 cm corresponding to 5 weeks 5 days. Right ovary was visualised separately from this mass.

Left adnexa irregular Gestational sac measuring approximately 0.8 cm corresponding to 5 weeks 4 days. Left ovary was visualised separately from this mass. Mild to Moderate hemoperitoneum was seen. Uterus was bulky however there was no intrauterine gestational sac.

The diagnosis of Bilateral adnexal ruptured ectopic gestation was made.

Preliminary investigations were done and patient was taken up for laparotomy in view of bilateral adnexal masses and hemoperitoneum.

Per operatively gross morphology was: Bilateral adnexal complex masses with moderate hemoperitoneum. Bilateral salpingostomy was performed. Patient’s post-operative period was uneventful.

Histopathology report came out to be gestational sacs in bilateral adnexa.

Figure 3: Trans vaginal Sonography shows Right adnexa heterogenous mass with two irregular sacs and hemoperitoneum. Left ovary is visualised.
However, live unilateral tubal twin ectopic pregnancy is a very rare condition and occurs in about 1:125,000 of pregnancies.[9] Several risk factors for tubal ectopic pregnancy were identified including active and passive cigarette/tobacco smoking, tubal damage as a result of surgery or infection (particularly Chlamydia trachomatis), and in vitro fertilization.[7] Furthermore, some authors indicated that the number of prior deliveries, ectopic pregnancy, and spontaneous or induced abortions were strongly associated with occurrence of ectopic pregnancy.[10,11] No such risk factors were present in our patients. It has been demonstrated that the history of ectopic pregnancy leads to an increased recurrence rate of about 10% and 25% for one and two/more previous ectopic pregnancy, respectively.[12]

A history of pelvic pain along with amenorrhea and vaginal bleeding is found in 45% of ectopic pregnancies [2] and probability of ectopic pregnancy in a patient with only abdominal pain and vaginal bleeding is 39%. The likelihood of ectopic pregnancy rises to 54% if the patient has other risk factors, including history of tubal surgery, previous ectopic pregnancy, or pelvic inflammatory disease.[1]

In addition, ultrasound evaluations have facilitated the early EP diagnosis which may lead to a reduction in maternal mortality and morbidity. Also, use of β-hCG assay, especially serial measurements, may improve these evaluations. Studies demonstrated that a β-hCG value of above 1500 mIU/ml corresponds to an approximately 91.5% detection of gestational sacs. [13] However, ultrasonographic findings of suspected adnexal mass and free liquid in the Douglas pouch along with an increased β-hCG levels, especially in association of risk factors, can help the early diagnosis of EP and reduce the related mortality and morbidity.

Twin-ectopic gestations are extremely rare. More than 100 twin tubal pregnancies have been reported, but 13 cases with cardiac activities demonstrated in both fetuses have been diagnosed [14]. The first case of a twin-ectopic pregnancy was described in 1994 [15]. Unilateral twin ectopic pregnancies occur in 1:200 ectopic pregnancies [16]. Most cases are monochorionic and monozygotic [17]. A rare case of diaminic dichorionic unilateral twin ectopic pregnancy was reported by Ghiike et al. and it appears this patient also had a diamniotic dichorionic twin [18]. They result from the abnormal implantation and maturation of the conceptus outside the endometrial cavity. Diagnosis is made by transvaginal ultrasound and it is crucial to make the diagnosis as soon as possible so that conservative tubal surgery can be planned.

It is reported that the incidence of tubal rupture in was about 32% and the risk of rupture rises about 2.5% for every 24 h period when untreated.[19] Until date, the surgical approach is the most reported option in literature to treat the unilateral tubal twin pregnancies.[20] There have been 4 cases of tubal twin pregnancies (3 unilateral, 1 bilateral) that methotrexate treatment has been tried,[21,22,23,24] However, Arik et al. suggested that the nonsurgical treatment may be favored in tubal twin EPs in case of stable maternal vital signs and negative fetal cardiac activities.[24] The tubal twin EP is a major health risk for women of childbearing capacity which may lead to life-threatening complications if not treated properly. Therefore, twin EP must be considered base on physical condition and occurs in about 1:125,000 of pregnancies.

Twin-ectopic gestations are extremely rare. More than 100 twin tubal pregnancies have been reported, but 13 cases with cardiac activities demonstrated in both fetuses have been diagnosed [14]. The first case of a twin-ectopic pregnancy was described in 1994 [15]. Unilateral twin ectopic pregnancies occur in 1:200 ectopic pregnancies [16]. Most cases are monochorionic and monozygotic [17]. A rare case of diaminic dichorionic unilateral twin ectopic pregnancy was reported by Ghiike et al. and it appears this patient also had a diamniotic dichorionic twin [18]. They result from the abnormal implantation and maturation of the conceptus outside the endometrial cavity. Diagnosis is made by transvaginal ultrasound and it is crucial to make the diagnosis as soon as possible so that conservative tubal surgery can be planned.

It is reported that the incidence of tubal rupture in was about 32% and the risk of rupture rises about 2.5% for every 24 h period when untreated.[19] Until date, the surgical approach is the most reported option in literature to treat the unilateral tubal twin pregnancies.[20] There have been 4 cases of tubal twin pregnancies (3 unilateral, 1 bilateral) that methotrexate treatment has been tried,[21,22,23,24] However, Arik et al. suggested that the nonsurgical treatment may be favored in tubal twin EPs in case of stable maternal vital signs and negative fetal cardiac activities.[24] The tubal twin EP is a major health risk for women of childbearing capacity which may lead to life-threatening complications if not treated properly. Therefore, twin EP must be considered base on physical examination and existence of risk factors and should be carefully looked for on ultrasound scanning, due to the potential mortality and morbidity associated with this condition.

Treatment of an ectopic pregnancy depends on its clinical presentation, size, and complications, and may entail conservative, medical, or surgical intervention. Successful laparoscopic management of tubal twin pregnancy and operative laparoscopic salpingectomy reported [25]. Salpingectomy is the management of choice in cases of large size of ectopic and ruptured ectopic gestation.

**Conclusion**

A spontaneous twin tubal pregnancy can occur in patients who have no known predisposing factor. Early diagnosis has made this disorder amenable to appropriate treatment. The high-resolution transvaginal sonography is very helpful in the diagnosis of this condition. Twin-ectopic gestations are extremely rare but there are treatment options. These have typically been classified as either conservative or surgical.
