Abstract

Fresh two-dimensional (2D) molybdenum disulfide (MoS$_2$) can absorb the hydrocarbon contamination from the ambient air and cause surface aging. Thus, understanding how the surface aging process of MoS$_2$ affects the interaction with biomolecules is crucial for its applications in the biomedical field. Here, we employed atomistic molecular dynamics simulations to investigate the interactions of fresh and aged MoS$_2$ nanosheets with POPE lipid membranes. Our results show that even though both the fresh and aged MoS$_2$ nanosheets are capable of spontaneous insertion into the POPE bilayer membrane, the fresh MoS$_2$ nanosheet displays significantly more robust interaction than the aged one. The potential mean force (PMF) calculations further confirm that the fresh MoS$_2$ nanosheet is more energetically favorable than the aged one in penetrating into the POPE lipid membranes, with the former having $\sim$17 kJ/mol stronger binding affinity than the later. This work provides a deeper understanding of the surface-aging-dependent interaction of MoS$_2$ nanosheet with biomolecules, which might help the design of better MoS$_2$-based nanodevices with appropriate surface properties.
**Introduction**

Molybdenum disulfide (MoS₂) is a member of the so-called transition-metal dichalcogenide (TMD) family, which has received great attention lately due to their unique physical and chemical properties. Previous studies have shown wide applications of MoS₂ nanosheets in optoelectronics,¹ field emission transistors,² gas sensors³⁻⁴ and hydrogen storage.⁵ More recently, MoS₂ nanosheets have also shown increasing interest in the biomedical field. For example, it has been reported that their strong near-infrared (NIR) absorption feature enables them to be used for photothermal therapy in cancer treatment.⁶⁻⁷ Also, the moderate direct bandgap of MoS₂ nanosheet has been explored for protein and DNA detections.⁸⁻⁹ While the strong absorbance of X-ray by Mo atoms makes it an appealing contrast agent in X-ray computed tomography imaging.⁷

Recent studies also demonstrate that the functionalized MoS₂ nanosheets have high inhibitory and bactericidal activities against ESKAPE pathogens by destructing their cell membranes.¹⁰ On the other hand, Yang et al. proposed that the antibacterial effects of MoS₂ nanosheets to the *Escherichia coli* (*E. coli*) is attributed by the chemical oxidation and membrane stress mechanisms.¹¹ In addition, MoS₂ nanosheets can also disrupt the integrity of the cell membranes and extract the phospholipids from the membrane bilayers.¹² These investigations have shown that the MoS₂ nanosheets hold strong interactions with cell membranes and other biomolecules, which makes them appealing to studies of nanotoxicity (and potential nanomedicine as antibacterial agents).

It is worth noting that the freshly prepared MoS₂ nanosheets (fresh MoS₂) can absorb hydrocarbons when they are exposed to air and induce surface aging (named as aged MoS₂), which thereby affects the surface hydrophobicity and topology and causes changes in the water contact angles (WCA) on the MoS₂ surface as evidenced by a series of variable values measured by different experiments.¹³⁻¹⁶ More importantly, the surface aging process of a MoS₂ nanosheet may result in a potential
effect on its interaction with biomolecules at the bio-nano interface, which is yet unknown to a large extent.

In this paper, we employ molecular dynamics (MD) simulations to investigate the underlying mechanism of the interactions between the MoS$_2$ nanosheets (with fresh vs. aged) and the POPE lipid membrane, aiming to understand how the surface aging process of MoS$_2$ affects interactions with biomolecules. Based on MD simulations, together with free energy calculations, we found that the fresh MoS$_2$ nanosheet presents a stronger binding affinity to the POPE lipid membranes than the aged one. The results suggest that the surface aging process of MoS$_2$ could affect the interaction with biomolecules.

**Results and Discussion**

Here, we applied the MD simulations to investigate the interactions of fresh and aged MoS$_2$ nanosheets with POPE lipid membrane. In order to efficiently model both fresh and aged MoS$_2$ surfaces, we have developed a simplified model by only adjusting the Lennard-Jones parameter, $\varepsilon_S$, (the depth of the potential well of a sulfur atom)$^{17}$, which demonstrates a surprisingly linear relationship between the $\varepsilon_S$ and water contact angle (WCA). In this study, the surface-aging dependent interaction of a MoS$_2$ nanosheet with membranes can thus be “achieved” using this simple MoS$_2$ force field model.$^{17-18}$ **Table 1** lists two sets of force field parameters for the fresh and aged MoS$_2$ nanosheets, respectively.

The initial configuration of a MoS$_2$ nanosheet and POPE lipid membrane is illustrated in **Fig. 1** (details can be seen in the Methods section). **Fig. 2** shows the final conformations of the fresh and aged MoS$_2$ nanosheets inserting into the lipid membrane from three independent trajectories. As can be clearly seen from **Fig. 2** that both the fresh and aged MoS$_2$ nanosheets finally bury themselves into the lipid
membranes with their orientations perpendicular to the membrane surfaces. In addition, both MoS$_2$ nanosheets (with fresh vs. aged) are mostly in direct contact with the hydrophobic tail of the lipid molecules and parallel to the tail chains. The results reveal that both the fresh and aged MoS$_2$ nanosheets can penetrate into the POPE lipid bilayer membrane, independent of their surface properties.

To better understand the interaction process, we further analyzed the time evolution of the atom contact number between the MoS$_2$ nanosheets (fresh vs. aged) and lipid membrane (Fig. 3a and c). Here, the atom contact number was recorded when the distance between a MoS$_2$ nanosheet and any heavy atom of lipid molecules is less than 0.5 nm. In addition, the binding conformations of the fresh and aged MoS$_2$ with the POPE membrane at four key snapshots were also illustrated in Fig. 3b and d. Initially, in the case of the fresh MoS$_2$ nanosheet, it moved freely in the water and has intermittent contacts with the lipid membrane, yielding an atom contact number less than 20 (0-5 ns). At $t = 5$ ns, fresh MoS$_2$ started to contact the membrane with a point-to-face orientation pointing to the target membrane. At $t = 18$ ns, the fresh MoS$_2$ has changed its binding conformation into a face-to-face orientation with an increase in atom contact number close to 100. At $t = 22$ ns, the fresh MoS$_2$ nanosheet has changed its conformation and is to tilt itself with one of the vertexes inserting into the membrane, along with a transient decrease in contact number compared to the value at 18 ns. Starting from $t = 22$ ns, the fresh MoS$_2$ continued to penetrate into the membrane with a dramatic increase in the atom contact number. After 65 ns, the interactions between the fresh MoS$_2$ and POPE membrane reached an equilibrium state with limited fluctuation in contact number (~275). As for the aged MoS$_2$, the general trend in the change of atom contact numbers and binding conformations is similar to the aforementioned fresh nanosheet as evidenced by the illustrations in Fig. 3e and d. These results suggest that both the MoS$_2$ nanosheets (fresh vs. aged) are capable of penetrating into the POPE lipid membranes.
We then analyzed the time evolution of the interaction energy between the MoS₂ nanosheets (fresh vs. aged) and lipid membrane to further illustrate the insertion processes. As can be seen from Fig. 4a and b, the van der Waals (vdW) force dominates the interaction energies in both fresh and aged MoS₂ nanosheets with POPE lipid membrane. Moreover, the vdW interaction energy of fresh MoS₂ is lower than that of aged MoS₂ in interacting with the POPE lipid membrane, whereas the Coulombic (Coul) interaction energy of fresh MoS₂ is slightly higher than that of aged MoS₂ (Fig. S1). Further analysis showed that the atom contact number between the fresh MoS₂ and head group is lower than that between the aged MoS₂ and head group. Conversely, the opposite trend is observed for the fresh and aged MoS₂ with the tail groups (Fig. 4c). In addition, Fig. 4d showed that the distance between the center of mass (COM) of the fresh MoS₂ and lipid membrane is shorter than that of the aged MoS₂ with the membrane, indicating that the fresh MoS₂ might have more damage to the cell membrane.

Additionally, we also calculated the binding free energies between the MoS₂ nanosheets (fresh vs. aged) and POPE lipid membranes by monitoring the relative free energy when pulling the MoS₂ nanosheets along the Z-direction perpendicular to the membrane, using the potential of mean force (PMF) method (details can be found in the Methods section). As seen in Fig. 5 that the free energy of the fresh MoS₂ is ~17 kJ/mol stronger than the aged one, which indicates that the fresh MoS₂ nanosheet is more energetically favorable to penetrate into the cell membrane than the aged one, though both the fresh and aged MoS₂ nanosheets exhibit spontaneous penetrating behaviors to the POPE membrane. Besides, the minimum of the PMF curves corresponds to the COM distance of 0.8 nm and 1.1 nm for the fresh and aged MoS₂, respectively, in agreement with Fig. 4d and consistent with the indication that the fresh MoS₂ might have more damage to the cell membrane.
Conclusion

In this work, we employed atomistic molecular dynamics simulations to investigate the interactions between MoS\textsubscript{2} nanosheets (with fresh vs. aged) and the POPE lipid membrane, aiming to understand how the surface aging process of a MoS\textsubscript{2} nanosheet affects its interaction with cell membranes. Our results show that even though both the fresh and aged MoS\textsubscript{2} nanosheets are able to insert into POPE bilayers, the fresh MoS\textsubscript{2} nanosheet presents significantly more robust interaction with the membrane than the aged one. Free energy calculations computed by the potential mean force (PMF) further verify that the membrane insertion process of the fresh MoS\textsubscript{2} nanosheet is more energetically favorable than the aged one, with the former showing \(\sim17\) kJ/mol more binding affinity than the latter. Our findings reveal that MoS\textsubscript{2} has a surface-aging-dependent interaction with cell membranes, which may be beneficial to future applications in biomedicine.

Methods

Molecular dynamics simulation

In this work, the triangular MoS\textsubscript{2} nanosheet (side length of 2.89 nm) was used due to its small size and was also proved to have the capacity in penetrating into the bilayer.\textsuperscript{19} The membrane with surface dimensions of 6.25 \(\times\) 6.25 nm\textsuperscript{2} was constructed by using CHARMM-Gui (http://www.charmm-gui.org), yielding 168 palmitoyloleoylphosphatidylethanolamine (POPE) lipids.\textsuperscript{20} Two types of MoS\textsubscript{2} nanosheets (with fresh vs. aged) were placed above the lipid membrane with a minimum distance of about 1.2 nm (as shown in Fig. 1). Two systems were placed in the same box (6.25 \(\times\) 6.25 \(\times\) 12.73 nm), containing 10473 water molecules, 48 Na ions and 48 Cl ions.

All MD simulations are carried out with the software package GROMACS (version 5.1.4).\textsuperscript{21} VMD software was utilized to visualize MD trajectories and draw snapshots.\textsuperscript{22} The force field parameters of the fresh and aged MoS\textsubscript{2} nanosheets were employed based on our previous works.\textsuperscript{17-18} The CHARMM 36 force field \textsuperscript{23-25} and
TIP3P water model were adopted for POPE molecules and water molecules, respectively. Following similar protocols in our previous studies, periodic boundary conditions of these systems were treated in all directions (x, y and z). The temperature and pressure were fixed at 300 K and 1 atm using v-rescale thermostat and semi-isotropic Parrinello-Rahman algorithm. The long-range electrostatic interactions were treated with the PME method, and the van der Waals (vdW) interactions were calculated with a cutoff distance of 1.2 nm. The geometrical properties of solute bonds associated with hydrogen were kept constant at their equilibrium values with the LINCS algorithm, and water geometry was also constrained using the SETTLE algorithm. All simulations were performed for 200 ns and data were collected every 10 ps.

**Potential of mean force (PMF)**

The PMF profiles of the fresh and aged MoS$_2$ nanosheets along the z-direction perpendicular to the membrane surface were calculated using umbrella sampling simulations. The distance (d) to the center of the membrane was restrained at a reference distance ($d_0$) with a harmonic force

$$F = k \times (d - d_0)$$

where $k$ is the force constant (2000 kJ mol$^{-1}$ nm$^{-2}$). The spacing of the sampling windows was 0.1 nm. For each $d_0$, the system was equilibrated for 2 ns, followed by a 10-ns productive run. The free energy profiles were obtained by the Weighted Histogram Analysis Method.
