Regret and Cumulative Constraint Violation Analysis for Distributed Online Constrained Convex Optimization

Xinlei Yi ©, Xiuixian Li ©, Senior Member, IEEE, Tao Yang ©, Senior Member, IEEE, Lihua Xie ©, Fellow, IEEE, Tianyou Chai ©, Life Fellow, IEEE, and Karl Henrik Johansson ©, Fellow, IEEE

Abstract—This article considers the distributed online convex optimization problem with time-varying constraints over a network of agents. This is a sequential decision making problem with two sequences of arbitrarily varying convex loss and constraint functions. At each round, each agent selects a decision from the decision set, and then only a portion of the loss function and a coordinate block of the constraint function at this round are privately revealed to this agent. The goal of the network is to minimize the network-wide loss accumulated over time. Two distributed online algorithms with full-information and bandit feedback are proposed. Both dynamic and static network regret bounds are analyzed for the proposed algorithms, and network cumulative constraint violation is used to measure constraint violation, which excludes the situation that strictly feasible constraints can compensate the effects of violated constraints. In particular, we show that the proposed algorithms achieve $O(T^{\max\{\kappa,1-\kappa\}})$ static network regret and $O(T^{1-\kappa/2})$ network cumulative constraint violation, where $T$ is the time horizon and $\kappa \in (0, 1)$ is a user-defined tradeoff parameter. Moreover, if the loss functions are strongly convex, then the static network regret bound can be reduced to $O(T^\kappa)$. Finally, numerical simulations are provided to illustrate the effectiveness of the theoretical results.

Index Terms—Cumulative constraint violation, distributed optimization, online optimization, regret, time-varying constraints.

I. INTRODUCTION

Online convex optimization is a promising framework for machine learning and has wide applications, such as online binary classification [1], dictionary learning [2], and online display advertising [3]. It can be traced back at least to the 1990s [4], [5], [6]. Simply speaking, online convex optimization is a sequential decision making problem with a sequence of arbitrarily varying convex loss functions. At each round, a decision maker selects a decision from the decision/constraint set and then the loss function at this round is revealed. The goal of the decision maker is to minimize the loss accumulated over time. For an online convex optimization algorithm, the standard performance metric is regret, which is the performance gap between the decision sequence induced by the algorithm and a benchmark in hindsight. If the benchmark is the optimal static (dynamic) decision sequence, then regret is called static (dynamic) regret.

Over the past decades, online convex optimization has been extensively studied, e.g., [7], [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18]. In these studies, the proposed algorithms usually are projection-based and the results basically ensure that sublinear static regret can be achieved. For example, the projection-based online gradient descent algorithm proposed in [7] achieved an $O(\sqrt{T})$ static regret bound, where $T$ is the time horizon. This is a tight bound up to constant factors [8]. The static regret bound can be reduced under more stringent strong convexity conditions on the loss functions [8], [10], [12], [13]. Note that the projection operator is performed at each round. It could yield heavy computation and/or storage burden when the constraint set is determined by a set of functional constraints. To tackle this challenge, online convex optimization with long term constraints was considered, e.g., [18], [19], [20], [21], [22], [23]. In this new problem, the constraints are relaxed to be soft long term constraints. In other words, instead of requiring the constraints to be satisfied at each round, the constraints should be satisfied in the long term on average. In addition to regret,
the other performance metric in this case is constraint violation, which is the violation of the cumulative constraint functions. The problem can be further extended to a more general scenario where the constraint functions are time-varying and revealed to the decision maker after the decision is chosen, e.g., [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34].

Distributed optimization methods are becoming core aspects of various important applications in view of flexibility and scalability to large-scale datasets and systems, and from the perspective of data privacy and locality [35]. Motivated by this, a distributed variation of the classic online convex optimization was considered, e.g., [36], [37], [38], [39], [40], [41], [42], [43], [44], [45]. In this setting, at each round the loss function is decomposed across a network of agents. Each agent selects a decision from the decision set and then its own portion of the loss function, i.e., the local loss function, at this round is revealed to itself only. The goal of the network is to minimize the network-wide loss accumulated over time, and the performance metric for a distributed algorithm is, hence, measured by network regret, i.e., the average of all individual regrets. Each agent’s individual regret is the difference between the cumulative global losses evaluated at this agent’s decision sequence and a benchmark in hindsight. In order to avoid the potential computation and/or storage challenge caused by the projection operator when using projection-based algorithms, distributed online convex optimization with long-term constraints was considered in [46], [47], and [48]. For this problem, network constraint violation can be similarly defined and also is a performance metric. For example, in [46], an $O(T^{0.5+\beta})$ static network regret bound and an $O(T^{1-\beta/2})$ network constraint violation bound were achieved, where $\beta \in (0, 0.5)$ is a user-defined parameter, which enables the tradeoff between these two bounds. In [49], the abovementioned distributed online convex optimization with long-term constraints was extended to a more general scenario where the constraint functions are time-varying and at each round only a coordinate block of the constraint function is privately revealed to each agent after its decision is chosen, and an $O(T^{\text{max}(\kappa, 1-\kappa)} + T^\kappa T_f)$ network regret bound and an $O(T^{\sqrt{2.2+2\kappa-2\kappa^2}} + T^{1+\kappa-b} P_f)$ network constraint violation bound were achieved, where $a, b \in (0, 1)$ with $a > b$ are user-defined tradeoff parameters and $P_f \geq 0$ is the path-length of the benchmark (see Theorem 1). Other forms of distributed variation of the centralized online convex optimization have also been considered, e.g., [50], [51], [52], [53], [54], [55], [56].

It should be pointed out that the commonly used (network) constraint violation metrics have a potential drawback since they implicitly allow constraint violations at some rounds to be compensated by strictly feasible decisions at other rounds. In order to avoid this drawback, a more strict metric, cumulative constraint violation, i.e., the constraint violation accumulated over time, was considered in [21], [23], [47], and [48]. For example, in [21], the centralized online convex optimization with long-term constraints was considered, and an $O(T^{\text{max}(\kappa, 1-\kappa)})$ static regret bound and an $O(T/\kappa)^{1/2}$ cumulative constraint violation bound were achieved, where $\kappa \in (0, 1)$ is a user-defined tradeoff parameter. These results were extended to the distributed setting with quadratic loss functions and linear constraint functions in [47], and further to the distributed setting with arbitrary convex loss and constraint functions in [48].

In this article, same as [49], we study the general online constrained convex optimization problem. However, different from [49], we adopt a more strict metric, network cumulative constraint violation. Moreover, we consider both full-information and bandit feedback scenarios. The full-information feedback means that the expressions or (sub)gradients of the loss and constraint functions are revealed, while the bandit feedback means that only the values of the loss and constraint functions are revealed at the sampling instance. We propose two distributed online algorithms to solve the problem, which have a good property that they do not use the time horizon or any other parameters related to the loss or constraint functions to design the algorithm parameters. We have the following contributions.

1) To the best of authors’ knowledge, this article is the first to consider cumulative constraint violation for distributed online convex optimization with time-varying constraints, see Remark 1 for more detailed explanations.

2) We show in Theorems 1 and 3 that the proposed algorithms achieve an $O(T^{\text{max}(\kappa, 1-\kappa)} + T^\kappa T_f)$ network regret bound and an $O(T/\kappa)^{1/2}$ network cumulative constraint violation bound. These bounds recover the results achieved by the centralized online algorithms proposed in [7], [11], and [31], and are smaller than the bounds achieved in [49] although the standard network constraint violation metric rather than the more strict metric was used in [49], see Remarks 3 and 6 for more detailed explanations.

3) We show in Corollaries 1 and 2 that the proposed algorithms achieve an $O(T^{\text{max}(\kappa, 1-\kappa)} + T^\kappa T_f)$ static network regret bound and an $O(T/\kappa)^{1/2}$ network cumulative constraint violation bound. These bounds generalize the results in [9], [14], [19], [20], [21], [25], [46], [47], and [48] to more general settings, and also improve the results in [46], see Remarks 4 and 7 for more detailed explanations.

4) When the loss functions are strongly convex, we show in Theorems 2 and 4 that the static network regret bound can be improved to $O(T^\kappa)$. This result generalizes the result in [46] to more general settings, see Remark 5 for more detailed explanations.

In conclusion, as explained at the end of Section III, the results in this article can be viewed as nontrivial extensions of existing results. The detailed comparison of this article to some of the related works is summarized in Table 1.\footnote{In this table, we do not list the dynamic regret since most of the listed works do not consider that.}

The rest of this article is organized as follows. Section II formulates the considered problem. Sections III and IV provide distributed online algorithms with full-information and bandit feedback, respectively, and analyze their regret and cumulative constraint violation bounds. Section V gives simulation examples. Finally, Section VI concludes this article.

**Notations:** All inequalities and equalities throughout this article are understood componentwise. $R^p$ and $R^p_+$ stand for the set of $p$-dimensional vectors and nonnegative vectors, respectively. $N_+$ denotes the set of all positive integers. $[n]$ represents the set $\{1, \ldots, n\}$ for any positive integer $n$. $\| \cdot \|$ and $\langle \cdot, \cdot \rangle$ stands for the Euclidean norm (1-norm) for vectors and the induced 2-norm (1-norm) for matrices. $B^p$ and $S^p$ are the unit ball and sphere centered around the origin in $R^p$ under Euclidean norm, respectively. $x^\top$ denotes the transpose of a vector or a matrix. $\langle x, y \rangle$ represents the standard inner product of two vectors $x$ and $y$.
$y, 0_m$ denotes the column zero (one) vector with dimension $m$, col($z_1, \ldots, z_n$) is the concatenated column vector of $z_i \in \mathbb{R}^{m_i}, i \in [n]$. The notation $A \otimes B$ denotes the Kronecker product of matrices $A$ and $B$. For a set $\mathcal{K} \subseteq \mathbb{R}^P$, $\mathcal{P}_\mathcal{K}(\cdot)$ denotes the projection operator, i.e., $\mathcal{P}_\mathcal{K}(x) = \arg\min_{x \in \mathcal{K}} \|x - y\|_2, \forall x \in \mathbb{R}^P$. For simplicity, $[\cdot]_+$ is used to denote $\mathcal{P}_{\mathcal{R}_+^{\mathbb{R}^P}}(\cdot)$. For a scalar function $f : \mathbb{R}^p \to \mathbb{R}$, let $\partial f(x)$ denote the (sub)gradient of $f$ at $x$, and let $\partial [f(x)]_+$ denote the (sub)gradient of $[f(x)]_+$ at $x$, i.e.,

$$\partial [f(x)]_+ = \begin{cases} 0_p, & \text{if } f(x) < 0 \\ \partial f(x), & \text{otherwise.} \end{cases}$$

For a vector function $f = [f_1, \ldots, f_d]^\top : \mathbb{R}^p \to \mathbb{R}^d$, its (sub)gradient at $x$ is written as $\partial f(x) = [\partial f_1(x), \ldots, \partial f_d(x)]^\top \in \mathbb{R}^{p \times d}$. Similarly, the (sub)gradient of $[f(x)]_+ = [\partial [f_1(x)]_+, \ldots, \partial [f_d(x)]_+]$ at $x$ is written as $\partial [f(x)]_+ = [\partial [f_1(x)]_+, \ldots, \partial [f_d(x)]_+] \in \mathbb{R}^{p \times d}$.

### II. Problem Formulation

In this section, we formulate the considered problem and provide the motivating examples at the end of this section.

We consider distributed online convex optimization with time-varying constraints. Specifically, consider a network of $n$ agents indexed by $i \in [n]$, which can communicate with each other according to a time-varying directed graph which will be described shortly. Let $\{f_{i,t} : \mathcal{X} \to \mathbb{R}\}$ and $\{g_{i,t} : \mathcal{X} \to \mathbb{R}^m\}$ be sequences of local convex loss and constraint functions over time $t = 1, 2, \ldots$, respectively, where $\mathcal{X} \subseteq \mathbb{R}^n$ is a known convex set, $p$ and $m$ are positive integers, and $g_{i,t} \leq 0_m$ is the local constraint. At time $t$, each agent $i$ selects a decision $x_{i,t} \in \mathcal{X}$. After the selection, the agent receives full-information or bandit feedback about the loss function $f_{i,t}$ and constraint function $g_{i,t}$, which is held privately by this agent. The objective is to design distributed sequential decision selection algorithms such that the network-wide loss accumulated over time is minimized. Similar to [46], [47], [48], [49], we use network regret and cumulative constraint violation to measure performance of such an algorithm. Specifically, network regret and cumulative constraint violation are defined as

$$\text{Net-Reg}\{(x_{i,t}, y_{T}) : \frac{1}{n} \sum_{t=1}^{T} \sum_{i=1}^{n} f_i(x_{i,t}) - \sum_{t=1}^{T} f_i(y_t) \}$$

and

$$\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g_i(x_{i,t})\|_2$$

respectively, where $T$ is the time horizon, $y_{T} = \{y_1, \ldots, y_T\}$ is a benchmark, and

$f_i(x) = \frac{1}{n} \sum_{j=1}^{n} f_{j,t}(x)$

$g_i(x) = \text{col}(g_{i,1}(x), \ldots, g_{i,T}(x))$

are the global loss and constraint functions, respectively.

In the literature, there are two commonly used benchmarks. One is the optimal dynamic decision sequence

$x_{t,T} = (x_{t,1}, \ldots, x_{t,T})$

where $x_{t,T} \in \mathcal{X}$ denotes the minimizer of $f_t(x)$ constrained by $g_t(x) \leq 0_m$ with $m = \sum_{t=1}^{n} m_t$. In other words, $x_{t,T}$ is the best choice by knowing the functions $f_t$ and $g_t$ in advance. In order to guarantee that the optimal dynamic decision sequence always exists, we assume that for any $T \in \mathbb{N}_+$, the set of all the feasible decision sequences

$$\mathcal{X}_T = \{(x_1, \ldots, x_T) : \forall t \in [T] \}$$

is nonempty. In this case, $\text{Net-Reg}\{(x_{i,t}, y_{T}) : \forall t \in [T]\}$ is called the dynamic network regret. Another benchmark is the optimal static decision sequence

$x_{t,T} = (x_{t,1}, \ldots, x_{t,T})$

where $x_{t,T} \in \mathcal{X}$ denotes the minimizer of $\sum_{t=1}^{T} f_t(x)$ constrained by $g_t(x) \leq 0_m$, $\forall t \in [T]$. Similar to above, in order to guarantee that the optimal static decision sequence always exists, we assume that for any $T \in \mathbb{N}_+$, the set of all the feasible static decision sequences

$$\tilde{\mathcal{X}}_T = \{(x, \ldots, x) : \forall t \in [T] \} \subseteq \mathcal{X}_T$$

is nonempty.
is nonempty. In this case, $\text{Net-Reg}(\{x_{i,t}\}, \tilde{x}_{[T]})$ is called the static network regret. The network cumulative constraint violation $\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g(x_{i,t})\|_+$ is more strict than the network constraint violation $\frac{1}{n} \sum_{i=1}^{n} \|\sum_{t=1}^{T} g(x_{i,t})\|_+$. Since

$$
\frac{1}{n} \sum_{i=1}^{n} \left\| \sum_{t=1}^{T} g(x_{i,t}) \right\|_+ \leq \frac{1}{n} \sum_{i=1}^{n} \left\| \sum_{t=1}^{T} g(x_{i,t}) \right\|_+
$$

For simplicity purposes, we use standard constraint violation metrics to refer to the metrics that take the summation over rounds before the projection, such as the network constraint violation $\frac{1}{n} \sum_{i=1}^{n} \left\| \sum_{t=1}^{T} g(x_{i,t}) \right\|_+$. The standard constraint violation metrics are commonly used in the literature, e.g., [19], [20], [25], [26], [27], [28], [29], [30], [31], [46], [49], but have the drawback that they implicitly allow constraint violations at some rounds to be compensated by strictly feasible decisions at other rounds. It is straightforward to see that the network cumulative constraint violation $\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g(x_{i,t})\|_+$ does not have such a drawback.

Note that each agent alone cannot compute network regret and cumulative constraint violation since it does not know other agents’ local loss and constraint functions. Agents can use a consensus protocol to collaborate. Therefore, agents need to communicate with each other. We assume that agents are allowed to share their decisions through a communication network modeled by a time-varying directed graph. Specifically, let $G_t = (V, E_t)$ denote the directed graph at the $t$th round, where $V = [n]$ is the agent set and $\mathcal{E}_t \subseteq V \times V$ be the edge set. A directed edge $(j, i) \in \mathcal{E}_t$ means that agent $j$ can receive data from agent $i$ at the $t$th round. Let $\mathcal{N}_i^\text{in}(G_t) = \{j \in [n] \mid (j, i) \in \mathcal{E}_t\}$ and $\mathcal{N}_i^\text{out}(G_t) = \{j \in [n] \mid (i, j) \in \mathcal{E}_t\}$ be the sets of in- and out-neighbors, respectively, of agent $i$ at the $t$th round. A directed path is a sequence of consecutive directed edges. A directed graph is said to be strongly connected if there is at least one directed path from any agent to any other agent in the graph. The adjacency (mixing) matrix $W_t \in \mathbb{R}^{n \times n}$ fulfills $|W_{t}|_{ij} > 0$ if $(i, j) \in \mathcal{E}_t$ or $i = j$, and $|W_{t}|_{ij} = 0$ otherwise.

We make the following standing assumption on the loss and constraint functions.

**Assumption 1:**

1. The set $X$ is convex and closed. Moreover, it contains the ball of radius $r(X)$ centered at the origin and is contained in the ball of radius $R(X)$, i.e.,

$$r(X)B^p \subseteq X \subseteq R(X)B^p.$$  \hspace{1cm} (5)

2. For any $i \in [n]$, $t \in \mathbb{N}_+$, the functions $f_{i,t}$ and $g_{i,t}$ are convex. Moreover, there exists a constant $F_1$ such that

$$\|f_{i,t}(x) - f_{i,t}(y)\| \leq F_1$$  \hspace{1cm} (6a)

$$\|g_{i,t}(x)\| \leq F_1 \quad \forall i \in [n], t \in \mathbb{N}_+, x, y \in X.$$  \hspace{1cm} (6b)

3. For any $i \in [n]$, $t \in \mathbb{N}_+$, $x \in X$, the subgradients $\partial f_{i,t}(x)$ and $\partial g_{i,t}(x)$ exist. Moreover, there exists a constant $F_2$ such that

$$\|\partial f_{i,t}(x)\| \leq F_2$$  \hspace{1cm} (7a)

$$\|\partial g_{i,t}(x)\| \leq F_2 \quad \forall i \in [n], t \in \mathbb{N}_+, x \in X.$$  \hspace{1cm} (7b)

The following assumption is made on the graph.

**Assumption 2:** For any $t \in \mathbb{N}_+$, the directed graph $G_t$ satisfies the following conditions.

a) There exists a constant $\omega \in (0, 1)$, such that $|W_{t}|_{ij} \geq \omega$ if $|W_{t}|_{ij} > 0$.

b) The mixing matrix $W_t$ is doubly stochastic, i.e.,

$$\sum_{i=1}^{n} |W_{t}|_{ij} = \sum_{j=1}^{n} |W_{t}|_{ij} = 1, \forall i, j \in [n].$$

c) There exists an integer $B > 0$ such that the directed graph $(V, \cup_{t=0}^{B} \mathcal{E}_{t+B})$ is strongly connected.

**Remark 1:** To the best of authors’ knowledge, this article is the first to consider cumulative constraint violation for distributed online convex optimization with time-varying constraints. The problem considered in this article is a distributed variation of the centralized online convex optimization with time-varying constraints considered in [25], [26], [27], [28], [29], [30], and [31]. The same distributed online constrained convex optimization problem had also been considered in [49], but in [49], the standard network constraint violation metric was used. It should be pointed out that the considered problem is more general than the distributed problems considered in [46], [47], and [48]. Specifically, in [46] and [48], the global constraint function is time-invariant and known by each agent in advance, and in [46], the standard network constraint violation metric was used. In [47], the local loss functions are quadratic and the global constraint function is time-invariant, linear, and known by each agent in advance. It should also be highlighted that the considered problem in this article and the distributed online optimization with time-varying coupled inequality constraints considered in [54] and [55] are different kinds of distributed problems. Specifically, in [54] and [55] at the $t$th round the global loss function is $\sum_{t=1}^{n} f_{i,t}(x_i)$ and the constraints are $\sum_{i=1}^{n} g_{i,t}(x_i) \leq 0_{m}$, where $x_i \in \mathbb{R}^p$ with $p_i$ being a positive integer. Therefore, the algorithms proposed in [54] and [55] cannot be used to solve the problem considered in this article. Moreover, the standard constraint violation metric was used in [54] and [55] and it is unclear how to extend the results to the more strict constraint violation metric.

Noting that the problem considered in this article incorporates the problems considered in [25], [26], [27], [28], [29], [30], [31], [46], and [47], the examples studied in these papers, such as online job scheduling [26], online network resource allocation [28], mobile fog computing in Internet of Things [29], online linear regressions [47], and online spam filtering task [48], motivate this article. We omit the details of these motivating examples due to space limitations. In the simulations, we use the distributed online linear regression problem with time-varying linear inequality constraints as an example to compare the performance of different algorithms.

### III. DISTRIBUTED ONLINE ALGORITHM WITH FULL-INFORMATION FEEDBACK

In this section, we consider the distributed online constrained convex optimization problem formulated in Section II with full-information feedback. We first propose a distributed online algorithm, and then derive network regret and cumulative constraint violation bounds for this algorithm.

#### A. Algorithm Description

Recall that at the $t$th round, the global loss and constraint functions are given in (3) and (4), respectively. The associated
regularized convex–concave function is
\[ A_t(x_t, q_t) := f_t(x_t) + q_t^T [g_t(x_t)] + \frac{\beta_{t+1}}{2} ||q_t||^2 \]
where \( x_t \in \mathbb{X} \) and \( q_t \in \mathbb{R}^m_t \) represent the primal and dual variables, respectively, and \( \beta_{t+1} \) is the regularization parameter. Here, the clipped constraint function \([g_t(x_t)]_+\) is used, which is essential for analyzing cumulative constraint violation. The primal and dual variables can be updated by the standard primal–dual algorithm
\[ x_{t+1} = P_X \left( x_t - \alpha_{t+1} \frac{\partial A_t(x_t, q_t)}{\partial x} \right) \]
\[ q_{t+1} = \left[ q_t + \gamma_{t+1} \frac{\partial A_t(x_t, q_t)}{\partial q} \right]_+ \]
where \( \alpha_{t+1} > 0 \) and \( \gamma_{t+1} > 0 \) are the stepsizes used in the primal and dual updates, respectively, and
\[ \omega_{t+1} = \frac{1}{n} \sum_{i=1}^n \partial f_i(x_t) + \partial [g_t(x_t)]_+ q_t. \]

We then modify the centralized algorithm (8) and (9) to a distributed manner. We use \( x_{i,t} \) to denote the local copy of the primal variable \( x_t \) and rewrite the dual variable in an agent-wise manner, i.e., \( q_t = \text{col}(q_{1,t}, \ldots, q_{n,t}) \) with each \( q_{i,t} \in \mathbb{R}^{m_i} \). Then, for each agent \( i \), \( z_{i,t+1} \) computed by the consensus protocol (11) is used to track the average estimation \( \frac{1}{n} \sum_{i=1}^n x_{i,t} \) and, thus, can be used to estimate \( x_t \). Moreover, \( \omega_{i,t+1} \) defined in (12) can be understood as a part of \( \omega_{t+1} \) that is available to agent \( i \). In this case, each \( x_{i,t+1} \) is updated by (13), which is similar to the updating rule (8), and the updating rule (9) can be executed in an agent-wise manner as
\[ q_{i,t+1} = \left[ (1 - \beta_{t+1}\gamma_{t+1}) q_{i,t} + \gamma_{t+1} [g_t(x_{i,t})]_+ \right]_+. \]

In order to avoid using the upper bounds of the loss and constraint functions and their subgradients to design the algorithm parameters \( \alpha_t, \beta_t, \gamma_t \), inspired by the algorithms proposed in [26], [27], and [54], we slightly modify the dual updating rule (10) as (14). As a result, the updating rule (8) and (9) can be executed in a distributed manner, which is given in pseudocode as Algorithm 1.

**Algorithm 1: Distributed Online Algorithm with Full-Information Feedback.**

**Input:** non-increasing and positive sequences \( \{\alpha_t\}, \{\beta_t\} \) and \( \{\gamma_t\} \).

**Initialize:** \( x_{1,1} \in \mathbb{X} \) and \( q_{1,1} = 0, m \), for all \( i \in [n] \).

**for** \( t = 1, \ldots \) **do**

**for** \( i = 1, \ldots, n \) **in parallel** **do**

- Broadcast \( x_{i,t} \) to \( N^m_t(G_t) \) and receive \( j, x_{j,t} \) from
- Observe \( \partial f_i(x_{i,t}), \partial q_{i,t}(x_{i,t}), \) and \( g_{i,t}(x_{i,t}) \);

**Update**

\[ z_{i,t+1} = \frac{\sum_{j=1}^n [W_{ij}] j x_{j,t}}{\sum_{j=1}^n [W_{ij}]}. \]

\[ \omega_{i,t+1} = \partial f_{i,t}(x_{i,t}) + \partial [g_{i,t}(x_{i,t})]_+ q_{i,t}. \]

\[ x_{i,t+1} = P_X(z_{i,t+1} - \alpha_{t+1} \omega_{i,t+1}). \]

\[ q_{i,t+1} = \left[ (1 - \beta_{t+1}\gamma_{t+1}) q_{i,t} + \gamma_{t+1} [g_{i,t}(x_{i,t})]_+ + \partial [g_{i,t}(x_{i,t})]_+ \right]_+ (x_{i,t+1} - x_{i,t}). \]

**end for**

**end for**

**Output:** \( \{x_{i,t}\} \).

We first characterize dynamic network regret and cumulative constraint violation bounds based on some natural vanishing stepsize sequences in the following theorem.

**Theorem 1:** Suppose Assumptions 1 and 2 hold. For all \( i \in [n] \), let \( \{x_{i,t}\} \) be the sequences generated by Algorithm 1 with
\[ \alpha_t = \frac{\alpha_0}{t^k}, \quad \beta_t = \frac{1}{t^n}, \quad \gamma_t = \frac{1}{t^{1-k}} \forall t \in \mathbb{N}_+, \]
where \( \alpha_0 > 0 \) and \( k \in (0, 1) \). Then, for any \( T \in \mathbb{N}_+ \) and any benchmark \( y_{[T]} \in \mathbb{X}_T \)
\[ \text{Net-Reg} (\{x_{i,t}\}, y_{[T]}): O \left( \frac{\alpha_0 T^{1-k} + T^n (1 + P_T)}{\alpha_0} \right). \]
\[ \frac{1}{n} \sum_{i=1}^n \|g_t(x_{i,t})\| = \mathcal{O}(\sqrt{\alpha_0 + 1/T^{2-k}}) \]
where \( P_T = \sum_{t=1}^T ||y_{t+1} - y_t|| \) is the path-length of the benchmark \( y_{[T]} \).

**Proof:** The explicit expressions of the right-hand sides of (16) and (17), and the proof are given in Appendix B.

**Remark 3:** It should be pointed out that the sequences in (15) do not use the time horizon \( T \) or any other parameters related to the loss or constraint functions. The intuition of designing the sequences in (15) is to make the network regret and cumulative constraint violation bounds provided in Lemma 7 in Appendix B as small as possible. The idea is original to [54] and has also been used in [49] and [55]. The omitted constants in the right-hand sides of (16) and (17) depend on the user-defined tradeoff parameter \( \kappa \), the number of agents \( n \), the constants related to the loss and constraint functions as assumed in Assumption 1, and the constants related to the communication network connectivity as assumed in Assumption 2. Theorem 1 shows that Algorithm 1 achieves improved performance compared
with the dynamic network regret bound $O(T^{\max(a,1-a+b)} + T^a P_T)$ and the standard network constraint violation bound $O(\sqrt{T^{\max(2\beta,2-\beta,2\beta-2a)} + T^{1+b} P_T})$ achieved by the distributed online algorithm proposed in [49], where $a, b \in (0, 1)$ and $a > b$. If setting $\alpha_0 = 1$ and $\kappa = 0.5$ in Theorem 1, the dynamic regret bound $O(\sqrt{T(1 + P_T)})$ for centralized online convex optimization achieved in [7] is recovered. If the path-length $P_T$ is known in advance, then setting $\alpha_0 = \sqrt{T + P_T}$ and $\kappa = 0.5$ in Theorem 1 recovers the dynamic regret bound $O(\sqrt{T(1 + P_T)})$. This is the optimal dynamic regret bound for centralized online convex optimization as shown in [15] and [23].

We then provide static network regret and cumulative constraint violation bounds for Algorithm 1 by replacing $y[t]$ with the static sequence $\tilde{x}_{[T]}$ in Theorem 1.

**Corollary 1:** Under the same conditions as stated in Theorem 1 with $\alpha_0 = 1$, for any $T \in \mathbb{N}_+$, it holds that

$$\text{Net-Reg}\{\{x_{i,t}\}, \tilde{x}_{[T]}\} = O(T^{\max(\kappa,1-\kappa)})$$

(18)

$$\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g_t(x_{i,t})\| = O(T^{1-\kappa/2}).$$

(19)

**Remark 4:** The results presented in Corollary 1 generalize the results in [20], [21], [25], and [47]. Specifically, by setting $\kappa = 0.5$ in Corollary 1, the result in [25] is recovered, although the algorithm proposed in [25] is centralized and the standard constraint violation metric rather than the more strict metric is used. The bounds presented in (18) and (19) are consistent with the result in [20], [21], and [48], although the proposed algorithm in [20] and [21] is centralized, the constraint functions in [20], [21], and [48] are time-invariant and known in advance, and the standard constraint violation metric is used in [20]. The same performance was also achieved in [47] when the loss functions are quadratic and the constraint functions are time-invariant, linear, and known in advance. Corollary 1 also shows that Algorithm 1 achieves improved performance compared with the static network regret bound $O(T^{0.5+\beta})$ and the standard network constraint violation bound $O(T^{-\beta/2})$ achieved by the distributed online algorithm proposed in [46], where $\beta \in (0, 0.5)$, although the global constraint functions in [46] are time-invariant and known in advance by each agent.

The static network regret bound in Corollary 1 at least is $O(\sqrt{T})$ and it can be reduced to strictly less than $O(\sqrt{T})$ if the local loss functions $f_{i,t}(x)$ are strongly convex.

**Assumption 3:** For any $i \in [n]$ and $t \in \mathbb{N}_+$, the functions $f_{i,t}(x)$ are strongly convex with convex parameter $\mu > 0$ over $\mathbb{R}$, i.e., for all $x, y \in \mathbb{R}$,

$$f_{i,t}(x) \geq f_{i,t}(y) + \langle x - y, \partial f_{i,t}(y) \rangle + \frac{\mu}{2} \|x - y\|.$$  

(20)

**Theorem 2:** Suppose Assumptions 1–3 hold. For all $i \in [n]$, let $\{x_{i,t}\}$ be the sequences generated by Algorithm 1 with

$$\alpha_t = \frac{1}{\sqrt{t}}, \beta_t = \frac{1}{t^\kappa}, \gamma_t = \frac{1}{\sqrt{t}}, \quad \forall t \in \mathbb{N}_+$$

(21)

where $c \in \max(\kappa, 1 - \kappa), 1$ and $\kappa \in (0, 1)$. Then, for any $T \in \mathbb{N}_+$, it holds that

$$\text{Net-Reg}\{\{x_{i,t}\}, x_{[T]}^*\} = O(T^c)$$

(22)

$$\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g_t(x_{i,t})\| = O(T^{1-\kappa/2}).$$

(23)

**Proof:** The explicit expressions of the right-hand sides of (22) and (23), and the proof are given in Appendix C. 

**Remark 5:** Theorem 2 shows that under the strongly convex assumption Algorithm 1 achieves the same static network regret and constraint violation bounds as the distributed algorithm proposed in [46]. However, in [46], the standard constraint violation metric rather than the more strict metric is used, and the global constraint functions are time-invariant and known in advance by each agent. Moreover, in [46], the convex parameter and the upper bound of the subgradients of the loss and constraint functions need to be known in advance to design the algorithm parameters. However, the bounds presented in (22) and (23) are larger than the bounds achieved by the centralized and distributed algorithms, respectively, proposed in [21] and [48] for strongly convex loss functions. We think this is acceptable since Algorithm 1 is suitable for a more general scenario where not only the constraints are time-varying but also each agent only knows a coordinate block of the constraint function at each round. Moreover, it does not use any parameters related to the loss and constraint functions. In contrast, the algorithms proposed in [21] and [48] use the upper bound of the subgradients of the loss and constraint functions to design the stepsizes, and it is unclear whether the results in [21], [48] can still be achieved or not after extending the algorithms to suit the general scenario as considered in this article. It is our ongoing work to design new distributed online algorithms such that they can achieve the same regret and cumulative constraint violation bounds as achieved by the centralized algorithm proposed in [21].

Before ending this section, we would like to present some discussions on the stepsizes. Algorithm 1 uses vanishing stepsizes as shown in (15) and (21), while there are some online algorithms, such as the online algorithms proposed in [11], [12], [43], and [45], used constant stepsizes. However, using vanishing stepsizes does not mean that Algorithm 1 cannot be used for infinite horizons, since the results stated above hold for any time horizons, which guarantee that Algorithm 1 can be used for infinite horizons. By the way, it should be mentioned that [11], [12], [43], [45] all assumed that the cost functions are smooth, i.e., the gradients of the cost functions are Lipschitz continuous. Such an assumption is rarely used in the papers considered vanishing stepsizes. Moreover, to the best of authors’ knowledge, in the study of online convex optimization with long term constraints, there are no studies that consider vanishing stepsizes. We think that one possible reason for this is as follows. In the analysis in [11], [12], [43], and [45], the inequality that $f_t(x_t) - f_t(x_t^*) \geq 0$ is explicitly or implicitly used. For example, that inequality has been explicitly used below (32) in the proof of [11] and implicitly used to yield (29) in [45]. However, when studying online convex optimization with long term constraints that inequality may not hold since when choosing $x_t$ the constraints can be violated. Therefore, it is challenging to design online algorithms with vanishing stepsizes for online convex optimization with long term constraints and analyze their performance.

Moreover, we would like to point out that compared with related studies, the consideration of the more strict constraint violation metric is a contribution but not the key contribution of this section and does not cause significant challenges for the performance analysis either. Actually, some existing results can be extended to the scenario under the more strict constraint violation metric when using the clipped constraint functions to replace the original constraint functions. Instead, the key
contributions of this section are (a) proposing a distributed algorithm for the general online constrained convex optimization problem, which incorporates various problems studied in the literature as special cases and (b) showing the proposed algorithm achieves the same or even better performance measured by regret and the more strict constraint violation metric as explained in the above remarks, which also make the proofs more challenging. Simply speaking, the main challenge in the proofs is how to handle the error caused by the inconsistency in the local decisions at each round. It should be mentioned that due to the distributed setting the proofs are much more complicated than that for the centralized algorithms. Moreover, the proofs are different from [46], [47], and [48] since we achieve strictly better results than [46] as explained in Remark 4, and our algorithm is different from the algorithms in [47] and [48] even when considering the same problem settings as [47], [48]. Similar discussions also hold for the results in the following section. In conclusion, the results in this article can be viewed as nontrivial extensions of existing results.

IV. DISTRIBUTED ONLINE ALGORITHM WITH BANDIT FEEDBACK

To handle the situations where the entire function and gradient information are not available, in this section, we focus on the bandit feedback, where at each round each agent can sample the values of its local loss and constraint functions at two points.

A. Algorithm Description

Under the bandit feedback setting each agent $i$ does not know the subgradients $\partial f_i(x_{i,t})$ and $\partial g_i(x_{i,t})$. Inspired by the two-point gradient estimator proposed in [9] and [14], these subgradients can be estimated by

$$
\hat{\partial f_i}(x_{i,t}) = \frac{P}{\delta_t} (f_{i,t}(x_{i,t} + \delta_t u_{i,t}) - f_{i,t}(x_{i,t})) u_{i,t} \in \mathbb{R}^p
$$

and

$$
\hat{\partial g_i}(x_{i,t}) = \frac{P}{\delta_t} ([g_i(x_{i,t} + \delta_t u_{i,t})]_+ - [g_i(x_{i,t})]_+)^T \otimes u_{i,t} \in \mathbb{R}^{p \times m_i},
$$

where $u_{i,t} \in \mathbb{S}^p$ is a uniformly distributed random vector, $\delta_t \in (0, r(X)\xi_t)$ is an exploration parameter, $\xi_t \in (0, 1)$ is a shrinkage coefficient, and $r(X)$ is a known constant given in the first part in Assumption 1.

Combining our Algorithm 1 with the above two-point gradient estimators, our algorithm for the bandit setting is outlined in pseudocode as Algorithm 2.

| Algorithm 2: Distributed Online Algorithm With Bandit Feedback. |
|---------------------------------------------------------------|
| **Input:** non-increasing sequences $\{\alpha_t\}, \{\beta_t\}, \{\gamma_t\} \subseteq (0, +\infty), \{\xi_t\} \subseteq (0, 1), \text{ and } \{\delta_t\} \subseteq (0, r(X)\xi_t).$ |
| **Initialize:** $x_{i,1} \in (1 - \xi_1)X$ and $q_{i,1} = 0_m$, for all $i \in [n]$. |

| **Output:** $\{x_{i,t}\}$. |

B. Performance Analysis

This section analyzes network regret and cumulative constraint violation bounds for Algorithm 2.

Similar to the performance analysis for Algorithm 1. We have the following results.

**Theorem 3:** Suppose Assumptions 1 and 2 hold. For all $i \in [n]$, let $\{x_{i,t}\}$ be the sequences generated by Algorithm 2 with

$$
\alpha_t = \frac{\alpha_0}{t^{\kappa}}, \beta_t = \frac{1}{t^{\kappa}}, \gamma_t = \frac{1}{t^{1-\kappa}}, \xi_t = \frac{1}{t + 1}, \delta_t = \frac{r(X)}{t + 1}, t \in \mathbb{N}_+
$$

where $\alpha_0 > 0$ and $\kappa \in (0, 1)$. Then, for any $T \in \mathbb{N}_+$ and any benchmark $y[T] \in \mathcal{Y}_T$

$$
\mathbb{E}[\text{Net-Reg}(\{x_{i,t}\}, y[T])] = \mathcal{O} \left( \alpha_0 T^{1-\kappa} + \frac{T^\kappa (1 + P_T)}{\alpha_0} \right)
$$

(29)

$$
\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \mathbb{E}[\|g_i(x_{i,t})\|_+] = \mathcal{O} \left( \sqrt{\alpha_0 + 1}T^{\frac{\kappa}{\kappa - 1}} \right).
$$

(30)

**Proof:** The explicit expressions of the right-hand sides of (29) and (30), and the proof are given in the online version [57] due to space limitations.

**Remark 6:** By setting $\alpha_0 = \sqrt{1 + P_T}$ and $\kappa = 0.5$ in Theorem 3, the dynamic regret bound achieved by the centralized online algorithm with two-point bandit feedback proposed in [11] is recovered, although [11] only considered the static set constraint. Moreover, in this case, the dynamic regret and
constraint violation bounds achieved by the centralized online algorithm with two-point bandit feedback proposed in [31] are also recovered.

Replacing $y_{[T]}$ with the static sequence $\hat{x}_{[T]}$ in Theorem 3 gives static network regret and cumulative constraint violation bounds for Algorithm 2.

**Corollary 2:** Under the same conditions as stated in Theorem 3 with $\alpha_0 = 1$, for any $T \in \mathbb{N}_+$, it holds that

$$E[\text{Net-Reg}(\{x_{i,t}\}, \hat{x}_{[T]})] = O(T^{\max\{\kappa, 1-\kappa\}})$$

$$\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} E[\|g_t(x_{i,t})\|] = O(T^{1-\kappa/2}).$$

**Remark 7:** Corollary 2 shows that the results achieved by Algorithm 2 are more general than the results achieved by the online algorithms with two-point bandit feedback proposed in [9], [14], [19], and [47]. Specifically, by setting $\kappa = 0.5$ in Corollary 2, the results in [9], [14], and [19] are recovered, although the algorithms proposed in [9], [14], and [19] are all centralized, and the work in [9] and [14] only considered the static set constraint, and Mahdavi et al. [19] considered static inequality constraints and full-information feedback for the loss functions. The same bounds as presented in (31) and (32) were also achieved by the distributed online algorithm with two-point bandit feedback proposed in [47] when the loss functions are quadratic and the constraint functions are time-invariant, linear, and known in advance.

If Assumption 3 also holds, then the static network regret bound can be further reduced.

**Theorem 4:** Suppose Assumptions 1–3 hold. For all $i \in [n]$, let $\{x_{i,t}\}$ be the sequences generated by Algorithm 2 with

$$\alpha_t = \frac{1}{t^c}, \quad \beta_t = \frac{1}{t^p}, \quad \gamma_t = \frac{1}{t^{1-\kappa}}$$

$$\xi_t = \frac{1}{t+1}, \quad \delta_t = \frac{t(X)}{t+1}, \quad t \in \mathbb{N}_+$$

where $c \in [\max\{\kappa, 1-\kappa\}, 1)$ and $\kappa \in (0, 1)$. Then, for any $T \in \mathbb{N}_+$, it holds that

$$E[\text{Net-Reg}(\{x_{i,t}\}, \hat{x}_{[T]})] = O(T^c)$$

$$\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} E[\|g_t(x_{i,t})\|] = O(T^{1-\kappa/2}).$$

**Proof:** The explicit expressions of the right-hand sides of (34) and (35), and the proof are given in the online version [57] due to space limitations.

**Remark 8:** By comparing Theorem 1, Corollary 1, and Theorem 2 with Theorem 3, Corollary 2, and Theorem 4, respectively, we can see that the same network regret and cumulative constraint violation bounds are achieved under the same assumptions. In other words, in an average sense, the distributed online algorithm with two-point bandit feedback (Algorithm 2) is as efficient as the distributed online algorithm with full-information feedback (Algorithm 1).

**V. SIMULATIONS**

In this section, we evaluate the performance of Algorithms 1 and 2 with Algorithm 3 solving the distributed online linear regression problem with time-varying linear inequality constraints.

In this problem, the local loss and constraint functions are $f_{i,t}(x) = \frac{1}{2}(H_{i,t}x - z_{i,t})^2$ and $g_{i,t}(x) = A_{i,t}x - a_{i,t}$, respectively, where $H_{i,t} \in \mathbb{R}_+^{d_i \times p}$, $z_{i,t} \in \mathbb{R}_+^{d_i}$, $A_{i,t} \in \mathbb{R}_+^{m_i \times p}$, and $a_{i,t} \in \mathbb{R}_+^{m_i}$ with $d_i \in \mathbb{N}_+$. Moreover, the constraint set is $\mathcal{X} \subseteq \mathbb{R}_+^p$. At each time $t$, an undirected random graph is used as the communication graph. Specifically, connections between agents are random and the probability of two agents being connected is $\rho$. To guarantee that Assumption 2 holds, edges $(i, i+1)$, $i \in [n-1]$ are also added and $[W_i]_{ij} = \frac{1}{n}$ if $(i, j) \in \mathcal{E}_t$ and $[W_i]_{ii} = 1 - \sum_{j \neq i} [W_i]_{ij}$.

We set $n = 100$, $\rho = 0.1$, $d_i = 4$, $p = 10$, $m_i = 2$, and $\mathcal{X} = [-5, 5]^p$. Each component of $H_{i,t}$ is generated from the uniform distribution in the interval $[-1, 1]$ and $z_{i,t} = H_{i,t}1_p + z_{i,t}$, where $z_{i,t}$ is a standard normal random vector. Each component of $A_{i,t}$ and $a_{i,t}$ is generated from the uniform distribution in the interval $[0, 2]$ and $[0, 1]$, respectively.

Noting that there are no other distributed online algorithms to solve the considered problem due to the time-varying constraints, we compare our Algorithms 1 and 2 with the centralized algorithms with full-information feedback proposed in [25], [26], and [27] and the centralized algorithm with two-point bandit feedback proposed in [31]. Figs. 1 and 2 illustrate the evolutions of the average cumulative loss $\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} f_{i,t}(x_{i,t})/T$ and the average cumulative constraint violation $\frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \|g_{i,t}(x_{i,t})\|/T$, respectively. Fig. 1 shows that the algorithms with the same kind of information feedback have almost the same average cumulative loss and the algorithms with full-information feedback have smaller average cumulative loss, which are in accordance with the theoretical results. Fig. 2 shows that our proposed algorithms have smaller average cumulative constraint violation, which also matches the theoretical results since the standard constraint violation metric rather than the more strict metric was used in [25], [26], [27], and [31].

**VI. CONCLUSION**

In this article, we considered the distributed online convex optimization problem with time-varying constraints over a network of agents, which incorporates various problems studied in the literature. We proposed two distributed online algorithm to
Evolutions of $T^{-1} \sum_{i=1}^{n} \sum_{t=1}^{T} ||g(t_i, x_i)||_2^2 / T$.

Fig. 2. Evolutions of $T^{-1} \sum_{i=1}^{n} \sum_{t=1}^{T} ||g(t_i, x_i)||_2^2 / T$.

solvethis problem and analyzennetwork regret and cumulative constraint violation bounds for the proposed algorithms under different conditions. Our results can be viewed as nontrivial extensions of existing results, where we considered distributed and time-varying settings and used the more strict constraint violation metric. In the future, we will design new distributed online algorithms such that the static network regret bound can be further reduced under the strongly convex condition and the network cumulative constraint violation bound can be reduced when the constraint functions satisfy Slater’s condition. We will also consider how to reduce communication complexity.

APPENDIX A

A. Useful Lemmas

The following results are used in the proofs.

Lemma 1: (see [58], [59]) Let $W_t$ be the adjacency matrix associated with a time-varying graph satisfying Assumption 2. Then

$$\left| |\Psi_t|_{ij} - \frac{1}{n} \right| \leq \lambda \tau^{t-n} \quad \forall i, j \in [n], \quad \forall t \geq s \geq 1$$

(36)

where $\Psi_t = W_1 W_{t-1} \cdots W_s$, $\tau = (1 - w/4n^2)^{-2} > 1$, and $\lambda = (1 - w/4n^2)^{1/2} \in (0, 1)$.

Lemma 2 (Lemma 3 in [53]): Let $K$ be a nonempty closed convex subset of $\mathbb{R}^P$ and let $a, b, c$ be three vectors in $\mathbb{R}^P$. The following statements hold.

a) If $a \leq b$, then

$$||a||_1 \leq ||b||_1 \quad \text{and} \quad ||a||_+ \leq ||b||_+.$$  

(37)

b) If $x_1 = P_K(c - a)$, then for any $y \in K$, it holds that

$$2\langle x_1 - y, a \rangle \leq ||y - c||^2 - ||y - x_1||^2 - ||x_1 - c||^2.$$  

(38)

Lemma 3: Let $f: K \to \mathbb{R}^m$ be a vector function with $K \subset \mathbb{R}^P$ being a convex and closed set. Moreover, there exists $r(\mathbb{K}) > 0$ such that $r(\mathbb{K}) \mathbb{B}_P \subseteq K$. Denote

$$\hat{f}(x) = \frac{\partial}{\delta} \left( f(x + \delta u) - f(x) \right) \otimes u \quad \forall x \in (1 - \xi)K$$

and $f(x) = E_{u \in B}[f(x + \delta u)] \quad \forall x \in (1 - \xi)K$.

where $u \in \mathbb{S}^P$ is a uniformly distributed random vector, $\delta \in (0, r(\mathbb{K}) \xi], \xi \in (0, 1)$, and the expectation is taken with respect to uniform distribution. The following statements hold.

a) The function $f$ is differentiable on $(1 - \xi)K$ and

$$\nabla f(x) = E_{u \in B}[\partial f(x)] \quad \forall x \in (1 - \xi)K.$$  

b) If $f$ is convex on $K$, then $f$ is convex on $(1 - \xi)K$ and

$$f(x) \leq f(\hat{x}) \quad \forall x \in (1 - \xi)K.$$  

c) If $f$ is Lipschitz-continuous on $K$ with constant $L_0(f) > 0$, then $f$ is Lipschitz-continuous on $(1 - \xi)K$ with constants $L_0(f)$.

Moreover, for all $x \in (1 - \xi)K$

$$||f(x) - f(x)|| \leq \delta L_0(f), \quad ||\nabla f(x)|| \leq p L_0(f).$$  

d) If $f$ is bounded on $K$, i.e., there exists $F_0(f) > 0$ such that

$$||f(x)|| \leq F_0(f), \quad \forall x \in K,$$

then

$$||f(x)|| \leq F_0(f) \quad \forall x \in (1 - \xi)K.$$  

e) If $f$ is strongly convex with constant $\mu > 0$ over $K$, then

$$f(\hat{x}) \leq f(x) + \frac{\mu}{2} ||x - \hat{x}||^2.$$  

Proof: The proof is given in the online version [57].

B. Proof of Theorem 1

Denote $\bar{x}_t = \frac{1}{n} \sum_{i=1}^{n} x_{i,t}, \epsilon_{i,t} = x_{i,t} - z_{i,t}, \Delta_i(t) = \Delta_i(t)(\mu_i) = \frac{1}{2 \tau^2} ||\epsilon_{i,t} - \mu_i||^2 - (1 - \beta_i \gamma_t) ||\epsilon_{i,t} - \mu_i||^2 + (\partial \epsilon_{i,t}(x_{i,t-1}))^T (x_{i,t} - x_{i,t-1}), \xi_1 = 2 F_1 + F_2 R(\mathbb{X})^2, \xi_2 = \frac{\tau}{\lambda (1 - \tau)} \sum_{i=1}^{n} ||x_{i,t}||_1, \xi_3 = 2 F_2 + 2 \frac{F_2 R(\mathbb{X})^2}{\tau (1 - \tau)}, \xi_4 = 2 F_2 \xi_3 + 2 F_2 \xi_4, \xi_5 = 40 \xi_5, \mu_{ij} = \frac{\xi_1}{\tau + \xi_1 (1 + 2 \alpha_1 \gamma)}.$

To prove Theorem 1, we need some preliminary results. First, we quantify the disagreement among agents.

Lemma 4: If Assumption 2 holds. For all $i \in [n]$ and $t \in \mathbb{N}_+$, $x_{i,t}$ generated by Algorithm 1 satisfy

$$||x_{i,t} - \bar{x}_t|| \leq \tau \lambda^{t-2} \sum_{j=1}^{n} ||x_{j,t}||_1 + \frac{1}{n} \sum_{j=1}^{n} ||\epsilon_{j,t-1}||_1$$

$$+ ||\epsilon_{i,t-1}||_1 + \tau \sum_{s=1}^{t-2} \lambda^{t-s-2} \sum_{j=1}^{n} ||\epsilon_{j,s}||_1.$$  

(39)

Proof: The proof is given in the online version [57].

Then, we present a result on the evolution of local dual variables, which is critical to the analysis.

Lemma 5: Suppose Assumptions 1 and 2 hold and $\gamma_i \beta_i \leq 1$, $t \in \mathbb{N}_+$. For all $i \in [n]$ and $t \in \mathbb{N}_+$, the sequences $q_{i,t}$ generated by Algorithm 1 satisfy

$$\Delta_i(t)(\mu_i) \leq \xi_1 \gamma_t + \mu_i (q_{i,t-1})^T (x_{i,t-1}) + \frac{1}{2} \beta_i ||\mu_i||^2 + F_2 ||\mu_i|| ||x_{i,t} - x_{i,t-1}||.$$  

(40)

Proof: We use the following mathematical induction to prove

$$||\beta_i q_{i,t}|| \leq F_1.$$  

(41)

It is straightforward to see that $||\beta_i q_{i,1}|| \leq F_1$, $\forall i \in [n]$ since $q_{i,1} = 0_m, \forall i \in [n]$. Assume now that it is true at time slot $t$ for all $i \in [n]$, i.e., $||\beta_i q_{i,t}|| \leq F_1$. We show that it remains true at time slot $t + 1$.

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
Noting that $[g_{i,t}]_+$ is convex since $g_{i,t}$ is convex and that $\partial [g_{i,t}(x_{i,t})]_+$ is the subgradient of $[g_{i,t}]_+$ at $x_{i,t}$, we have

$$b_{i,t+1} \leq [g_{i,t}(x_{i,t+1})]_+. \quad (42)$$

Then, we have

$$\|g_{i,t+1}\| = \|(1 - \beta_{i,t+1} \gamma_{i,t}) g_{i,t} + \gamma_{i,t+1} b_{i,t+1}\| \leq \|(1 - \beta_{i,t+1} \gamma_{i,t}) g_{i,t} + \gamma_{i,t+1} [g_{i,t}(x_{i,t+1})]_+\| \leq (1 - \gamma_{i,t+1} \beta_{i,t+1}) \|g_{i,t}\| + \gamma_{i,t+1} \|g_{i,t}(x_{i,t+1})\| \leq (1 - \gamma_{i,t+1} \beta_{i,t+1}) \frac{F_1}{\beta_{i,t+1}} + \gamma_{i,t+1} F_1 \forall i \in [\mathcal{H}]$$

where the first inequality holds due to (14); the first inequality holds due to (37) and (42); the third inequality holds due to $\|\beta_{i} q_{i,t}\| \leq F_1$ and (6b); and the last inequality holds since the sequence $\{\beta_{i}\}$ is nonincreasing and $\gamma_{i,t} \beta_{i,t} \leq 1$. Thus, the result follows.

We then prove (40).

For any $\mu_{i} \in \mathbb{R}_+^m$, from that the projection $[\cdot]_+$ is nonexpansive and (14), we have

$$\|g_{i,t} - \mu_{i}\|^2 = \|[(1 - \beta_{i,t} \gamma_{i,t}) q_{i,t-1} + \gamma_{i,t} b_{i,t}]_+ - [\mu_{i}]_+\|^2 \leq \|(1 - \beta_{i,t} \gamma_{i,t}) q_{i,t-1} + \gamma_{i,t} b_{i,t} - \mu_{i}\|^2 \leq 2\gamma_{i,t} \|\beta_{i,t} q_{i,t-1} - \mu_{i}\|^2 + 2\gamma_{i,t} \|b_{i,t} - \beta_{i,t} q_{i,t-1}\|^2 + 2\gamma_{i,t} \|\beta_{i,t} q_{i,t-1} - \mu_{i}\|^2$$

$$= \|g_{i,t-1} - \mu_{i}\|^2 + 2\gamma_{i,t} \|b_{i,t} - \beta_{i,t} q_{i,t-1}\|^2 + 2\gamma_{i,t} \|\beta_{i,t} q_{i,t-1} - \mu_{i}\|^2 - 2\gamma_{i,t} \|\beta_{i,t} q_{i,t-1} - \mu_{i}\|^2 \leq \|g_{i,t-1} - \mu_{i}\|^2$$

We have

$$\|\beta_{i,t} - \beta_{i,t-1}\| \leq \|\beta_{i,t}\| + \|\beta_{i,t-1}\| \leq \|g_{i,t-1}(x_{i,t-1})\| + (\partial [g_{i,t-1}(x_{i,t-1})]_+)^T (x_{i,t-1} - x_{i,t-1})$$

$$\leq \|g_{i,t-1}(x_{i,t-1})\| + \|\partial [g_{i,t-1}(x_{i,t-1})]_+\| \|x_{i,t} - x_{i,t-1}\| + F_1 \leq 2F_1 + F_2 R(\mathcal{X}) \quad (43)$$

where the second inequality holds due to (41); the third inequality holds since $\{\beta_{i}\}$ is a nonincreasing sequence; and the last inequality holds due to (5), (6b), and (7b).

We have

$$-2\beta_{i,t} \gamma_{i,t} (q_{i,t-1} - \mu_{i})^T q_{i,t-1} \leq \beta_{i,t} \gamma_{i,t} \|\mu_{i}\|^2 - \|q_{i,t-1} - \mu_{i}\|^2. \quad (45)$$

From (7b), we have

$$-2\gamma_{i,t} \|\partial [g_{i,t-1}(x_{i,t-1})]_+\|^2 \leq 2\gamma_{i,t} F_2 \|\beta_{i,t}\| \|x_{i,t} - x_{i,t-1}\|. \quad (46)$$

Finally, from (43) to (46), we have (40).

Next, we provide network regret bound at one slot.

**Lemma 6:** Suppose Assumptions 1 and 2 hold. For all $i \in [\mathcal{H}]$, let $\{x_{i,t}\}$ be the sequences generated by Algorithm 1 and $\{y_t\}$ be an arbitrary sequence in $\mathcal{X}$, then

$$\frac{1}{n} \sum_{i=1}^{n} f_i(x_{i,t}) - f_i(y_t) \leq \frac{1}{n} \sum_{i=1}^{n} q_{i,t}(x_{i,t}) - b_{i,t+1} - \frac{1}{n} \sum_{i=1}^{n} \frac{1}{2\alpha_{t+1}} \|\epsilon_{i,t}\|^2$$

$$+ \frac{1}{n} \sum_{i=1}^{n} F_2 (\|x_{i,t} - \bar{x}_{i,t}\| + \|x_{i,t} - x_{i,t+1}\|) \leq \frac{1}{n} \sum_{i=1}^{n} \left(\|y_t - z_{i,t+1}\|^2 - \|y_{i,t} - z_{i,t+2}\|^2 \right) \quad (47)$$

**Proof:** From the third part in Assumption 1 and [10, Lemma 2.6], it follows that for all $i \in [n]$, $t \in \mathbb{N}_+$, $x, y \in \mathcal{X}$

$$|f_{i,t}(x) - f_{i,t}(y)| \leq F_2 \|x - y\| \quad (48a)$$

$$\|g_{i,t}(x) - g_{i,t}(y)\| \leq F_2 \|x - y\|. \quad (48b)$$

We have

$$\frac{1}{n} \sum_{i=1}^{n} f_i(x_{i,t}) - f_i(y_t) = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{1}{n} \sum_{j=1}^{n} f_j(x_{i,t}) \right) \leq \frac{1}{n} \sum_{i=1}^{n} f_i(x_{i,t}) + \frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} (f_j(x_{i,t}) - f_j(x_{j,t})) \leq \frac{1}{n} \sum_{i=1}^{n} f_i(x_{i,t}) + \frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} F_2 \|x_{i,t} - x_{j,t}\| \leq \frac{1}{n} \sum_{i=1}^{n} f_i(x_{i,t}) + \frac{2F_2}{n} \sum_{i=1}^{n} \|x_{i,t} - \bar{x}_{i,t}\| \quad (49)$$

where the first inequality holds due to (48a).

Noting that $f_i$ is convex, from (7a), we have

$$f_i(x_{i,t}) - f_i(y_t) \leq (\partial f_i(x_{i,t}), x_{i,t} - y_t) = (\partial f_i(x_{i,t}), x_{i,t} - x_{i,t+1}) + (\partial f_i(x_{i,t}), x_{i,t+1} - y_t) \leq F_2 \|x_{i,t} - x_{i,t+1}\| + (\partial f_i(x_{i,t}), x_{i,t+1} - y_t). \quad (50)$$

For the second term of (50), from (12), we have

$$\|\partial f_i(x_{i,t}), x_{i,t+1} - y_t\| \leq \|\omega_{i,t+1}, x_{i,t+1} - y_t\| + \|\partial [g_{i,t}(x_{i,t})]_+ + q_{i,t}, y_t - x_{i,t}\| + \|\partial [g_{i,t}(x_{i,t})]_+ + q_{i,t}, x_{i,t} - x_{i,t+1}\|. \quad (51)$$

Noting that $\partial [g_{i,t}(x_{i,t})]_+$ is the subgradient of the convex function $[g_{i,t}]_+$ at $x_{i,t}$, from $q_{i,t} \geq 0, \forall i \in [\mathcal{H}], \forall i \in [n]$, we have

$$\|\partial [g_{i,t}(x_{i,t})]_+ + q_{i,t}, y_t - x_{i,t}\| \leq q_{i,t}^T [g_{i,t}(y_t)]_+] - q_{i,t}^T [g_{i,t}(x_{i,t})]_+. \quad (52)$$

Applying (38) to the update (13)), we get

$$\|\omega_{i,t+1}, x_{i,t+1} - y_t\| \leq \frac{1}{2\alpha_{t+1}} \left(\|y_t - z_{i,t+1}\|^2 - \|y_{i,t} - z_{i,t+2}\|^2 - \|\epsilon_{i,t}\|^2 \right)$$
(53) where the last inequality holds since $W_{t+1}$ is doubly stochastic and $\|x\|^2$ is convex.

Combining (50)–(53), summing over $i \in [n]$, and dividing by $n$, and using $\sum_{i=1}^{n} [W_{t}]_{ij} = 1, \forall t \in \mathbb{N}_+$, yields (47).

Finally, we show network regret and cumulative constraint violation bounds.

**Lemma 7:** Suppose Assumptions 1 and 2 hold and $\gamma_t \beta_t \leq 1$, $t \in \mathbb{N}_+$. For all $i \in [n]$, let $\{x_{i,t}\}$ be the sequences generated by Algorithm 1. Then, for any benchmark $y_{[T]} \in \mathcal{X}_T$

\[
\text{Net-Reg}(\{x_{i,t}\}, y_{[T]}) 
\leq 4F_2\varepsilon_2 + \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \varepsilon_1 \gamma_t + 10\varepsilon_5 \alpha_t \right) |\alpha_T - 1| \|x_t\|^2 + \frac{2R(X)^2}{\alpha_T} P_T 
- \frac{1}{2n} \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} \right) \|q_{i,t}\|^2 
- \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{t=1}^{T} \|q_{i,t}\|^2 \right) 
\leq 4n \varepsilon_2 F_1 F_2 T + 2 \left( \frac{\varepsilon_1 \gamma_T}{\gamma_1} + \sum_{t=1}^{T} \beta_t + 6\varepsilon_6 \alpha_t \right) \left( nF_1 T \right) 
+ \sum_{t=1}^{T} n(\varepsilon_1 \gamma_t + 20\varepsilon_5 \alpha_t) + \frac{2n R(X)^2}{\alpha_{T+1}} 
- \frac{1}{2} \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} \right) \|q_{i,t} - \mu_0\|^2
\]  
(54)

**Proof:**

(i) We first provide a loose bound for network regret.

From (5), we have

\[
\|y_{t+1} - x_{i,t+1}\|^2 - \|y_t - x_{i,t+1}\|^2 
\leq \|y_{t+1} - y_t\| \|y_{t+1} - x_{i,t+1}\| + \|y_t - x_{i,t+1}\| 
\leq 4R(X) \|y_{t+1} - y_t\|.
\]
(56)

From (40), (47), and (56), and noting that $g_{i,t}(y_t) \leq \mu_{0,m}, \forall i \in [n]$ when $y_{[T]} \in \mathcal{X}_T$, we have

\[
\frac{1}{n} \sum_{i=1}^{n} \left( \Delta_{i,t+1}(\mu_i) + \mu_i \|g_{i,t}(x_{i,t})\| - \frac{1}{2} \beta_{t+1} \|\mu_i\|^2 \right)
\leq \varepsilon_1 \gamma_{t+1} + \frac{1}{n} \sum_{i=1}^{n} \Delta_{i,t+1}(\mu_i) + \frac{2R(X)}{\alpha_{t+1}} \|y_{t+1} - y_t\| 
+ \frac{1}{2n\alpha_{t+1}} \sum_{i=1}^{n} \|y_t - z_{i,t+1}\|^2 - \|y_t - z_{i,t+2}\|^2
\]
(57)

where

\[
\Delta_{i,t+1}(\mu_i) = F_2(\|\mu_i\| + 1) \|x_{i,t} - x_{i,t+1}\| 
+ 2F_2 \|x_{i,t} - \bar{x}_{i,t}\| - \frac{1}{2\alpha_{t+1}} \|\epsilon_{i,t}\|^2.
\]

From (47) is nonincreasing and (5), we have

\[
\sum_{t=1}^{T} \frac{1}{\alpha_{t+1}} \frac{\alpha_T}{\alpha_T} \|y_t - z_{i,t+1}\|^2 - \|y_t - z_{i,t+2}\|^2 
\leq \frac{1}{\alpha_1} \|y_1 - z_{i,2}\|^2 - \frac{1}{\alpha_{T+1}} \|y_{T+1} - z_{i,T+2}\|^2 
+ \sum_{t=1}^{T} \left( \frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_1} \right) 4R(X)^2 \leq \frac{4R(X)^2}{\alpha_{T+1}}.
\]
(58)

Summing (57) over $t \in [T]$, using (58), choosing $\mu_i = 0_{m_i}$, and setting $y_{T+1} = y_T$ gives

\[
\text{Net-Reg}(\{x_{i,t}\}, y_{[T]}) + \frac{1}{n} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i}) 
\leq \varepsilon_1 \gamma_{t+1} + \frac{1}{n} \sum_{i=1}^{n} \sum_{t=1}^{T} \Delta_{i,t+1}(0_{m_i}) 
+ \sum_{t=1}^{T} \left( \frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_1} \right) 4R(X)^2 \leq \frac{4R(X)^2}{\alpha_{T+1}}.
\]
(59)

To get (54), we then establish a lower bound for $\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i})$ and an upper bound for $\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i})$.

(i-1) Establish a lower bound for $\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i})$.

For any $T \in \mathbb{N}_+$, we have

\[
\sum_{i=1}^{T} \sum_{t=1}^{n} \Delta_{t+1}(\mu_i)
\]

\[
= \|q_{i,t+1} - \mu_i\|^2 - \frac{\|\mu_i\|^2}{2\gamma_{t+1}} 
+ \frac{1}{2} \sum_{t=1}^{T} \left( \frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} \right) \|q_{i,t} - \mu_i\|^2.
\]
(60)

Substituting $\mu_i = 0_{m_i}$ into (60) yields

\[
\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i}) \geq \frac{1}{2} \sum_{t=1}^{T} \left( \frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} \right) \|q_{i,t}\|^2.
\]
(61)

(i-2) Establish an upper bound for $\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(0_{m_i})$.
We have
\[ \sum_{t=1}^{T} \sum_{s=1}^{t-2} \sum_{j=1}^{n} \lambda^t \cdot s^2 \cdot \| e_{j,s}^s \| = \sum_{t=1}^{T-2} \sum_{j=1}^{n} \| e_{j,t}^s \| \sum_{s=0}^{T-2} \lambda^s \leq \frac{1}{1-\lambda} \sum_{t=1}^{T-2} \sum_{j=1}^{n} \| e_{j,t}^s \|. \tag{62} \]

From (39) and (62), for any \( \mu_i \in \mathbb{R}^{m_i} \), and \( \alpha > 0 \), we have
\[ \sum_{t=1}^{T} \sum_{i=1}^{n} \| \mu_i \| \| x_{i,t} - \bar{x}_t \| \leq \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \frac{1}{n} \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \| e_{j,t-1}^s \| \| \mu_i \| + \frac{T}{1-\lambda} \sum_{t=1}^{T-2} \sum_{i=1}^{n} \sum_{j=1}^{n} \| e_{j,t}^s \| \| \mu_i \| \leq \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \frac{T}{1-\lambda} \sum_{t=1}^{T-2} \sum_{i=1}^{n} \sum_{j=1}^{n} \| e_{j,t}^s \| \| \mu_i \| + \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{1}{aF_2 \alpha t} \| e_{j,t-1}^s \| ^2 + aF_2 \alpha \| \mu_j \| ^2 \right) + \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{1}{2anF_2 \alpha t} \| e_{j,t}^s \| ^2 + anF_2 \alpha ^2 \| \mu_j \| ^2 \right) \]
\[ = \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \frac{T}{1-\lambda} \sum_{t=1}^{T-2} \sum_{i=1}^{n} \sum_{j=1}^{n} \| e_{j,t}^s \| \| \mu_i \| + \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{1}{aF_2 \alpha t} \| e_{j,t-1}^s \| ^2 + aF_2 \alpha \| \mu_j \| ^2 \right) + \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{1}{2anF_2 \alpha t} \| e_{j,t}^s \| ^2 + anF_2 \alpha ^2 \| \mu_j \| ^2 \right) \]
\[ \leq \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \sum_{t=2}^{T} \sum_{i=1}^{n} \left( \frac{aF_3 \alpha t}{2(1-\lambda)} \| \mu_i \| ^2 + \frac{1}{aF_2 \alpha t} \| e_{j,t-1}^s \| ^2 \right). \tag{63} \]

For any \( \mu_i \in \mathbb{R}^{m_i} \) and \( \alpha > 0 \), we have
\[ \| \mu_i \| \| x_{i,t} - x_{i,t+1} \| \leq \| \mu_i \| \| x_{i,t} - z_{i,t+1} \| + \| \mu_i \| \| z_{i,t+1} - x_{i,t+1} \| \leq \| \mu_i \| \| x_{i,t} - z_{i,t+1} \| + \frac{1}{aF_2 \alpha t} \| e_{j,t}^s \| ^2 + \frac{aF_2 \alpha t + 1}{4} \| \mu_i \| ^2. \tag{64} \]

From (11) and \( \sum_{i=1}^{n} [W_{i,j}]_{ij} = \sum_{j=1}^{n} [W_{i,j}]_{ij} = 1 \), we have
\[ \sum_{i=1}^{n} \| x_{i,t} - z_{i,t+1} \| \leq \sum_{i=1}^{n} \left( \| x_{i,t} - \bar{x}_t \| + \| \bar{x}_t - z_{i,t+1} \| \right) \leq \sum_{i=1}^{n} \left( \| x_{i,t} - \bar{x}_t \| + \left\| \sum_{j=1}^{n} [W_{i,j}]_{ij} x_{j,t} \right\| \right) \leq \sum_{i=1}^{n} \| x_{i,t} - \bar{x}_t \| + \sum_{i=1}^{n} \sum_{j=1}^{n} [W_{i,j}]_{ij} \| \bar{x}_t - x_{j,t} \| \leq 2 \sum_{i=1}^{n} \| x_{i,t} - \bar{x}_t \|. \tag{65} \]

From (63)–(65), for any \( \mu_i \in \mathbb{R}^{m_i} \), and \( a > 0 \), we have
\[ \sum_{t=1}^{T} \sum_{i=1}^{n} F_2 \| \mu_i \| \| x_{i,t} - x_{i,t+1} \| \leq 2F_2 \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{2aF_2 \varepsilon_3 \alpha t}{\alpha t} \| \mu_i \| ^2 + \frac{2}{\alpha t} \| e_{j,t-1}^s \| ^2 \right) + \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{1}{\alpha t} \| e_{j,t}^s \| ^2 + \frac{aF_2 \alpha t + 1}{4} \| \mu_i \| ^2 \right) \leq 2F_2 \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{3}{\alpha t} \| e_{j,t}^s \| ^2 + a \varepsilon_4 \alpha t \| \mu_i \| ^2 \right). \tag{66} \]

Choosing \( \| \mu_i \| = 1 \) in (63) yields
\[ \sum_{t=1}^{T} \sum_{i=1}^{n} 2F_2 \| x_{i,t} - \bar{x}_t \| \leq 2nF_2 \varepsilon_2 + \sum_{t=2}^{T} \sum_{i=1}^{n} \left( 2aF_2 \varepsilon_3 \alpha t + \frac{2}{\alpha t} \| e_{j,t-1}^s \| ^2 \right). \tag{67} \]

Choosing \( \| \mu_i \| = 1 \) in (66) yields
\[ \sum_{t=1}^{T} \sum_{i=1}^{n} F_2 \| x_{i,t} - x_{i,t+1} \| \leq 2nF_2 \varepsilon_2 + \sum_{t=1}^{T} \sum_{i=1}^{n} \frac{3}{\alpha t} \| e_{j,t}^s \| ^2 + \sum_{t=1}^{T} \sum_{i=1}^{n} a \varepsilon_4 \alpha t. \tag{68} \]

Combining (67) and (68), and choosing \( a = 10 \) yields
\[ \sum_{t=1}^{T} \sum_{i=1}^{\Delta t_{i,t+1}(X_{m_i})} \leq 4nF_2 \varepsilon_2 + \sum_{t=1}^{T} \sum_{i=1}^{n} a \varepsilon_5 \alpha t. \tag{69} \]

(i-3) Combining (69), (61), and (59) yields (54).

(ii) We first provide a loose bound for network cumulative constraint violation.

We have
\[ \mu_i^T [g_{i,t} (x_{i,t})]_+ = \mu_i^T [g_{i,t} (x_{i,t})]_+ + \mu_i^T [g_{i,t} (x_{i,t})]_+ - \mu_i^T [g_{i,t} (x_{i,t})]_+ \geq \mu_i^T [g_{i,t} (x_{i,t})]_+ - \| \mu_i \| [g_{i,t} (x_{i,t})]_+ - [g_{i,t} (x_{i,t})]_+ \]
\[ \geq \mu_i^T [g_{i,t} (x_{i,t})]_+ - \| \mu_i \| [g_{i,t} (x_{i,t})]_+ - [g_{i,t} (x_{i,t})]_+ \]
\[ \geq \mu_i^T [g_{i,t} (x_{i,t})]_+ - F_2 \| \mu_i \| [x_{i,t} - x_{i,t+1} \]
\[ \geq \mu_i^T [g_{i,t} (x_{i,t})]_+ - F_2 \| \mu_i \| [x_{i,t} - \bar{x}_t] + [x_{j,t} - \bar{x}_t] \]
Combining (57) and (70), setting \( y_t = y \), and summing over \( j \in [n] \) yields
\[
\begin{align*}
&\sum_{i=1}^{n} \left( \Delta_{i,t+1}(\mu_i) + \frac{1}{n} \sum_{j=1}^{n} \mu_i^T \left[ g_i(x_j,y) \right] + \frac{1}{2} \beta_{t+1} \| \mu_i \|^2 \right) \\
+ &\sum_{i=1}^{n} f_i(x_j,y) - n f_i(y)
\end{align*}
\]
\[
\leq n \varepsilon_1 \gamma_{t+1} + \sum_{i=1}^{n} \Delta_{i,t+1}(\mu_i) + \frac{1}{n} \Delta_t \\
+ &\frac{1}{2 \alpha_{t+1}} \sum_{i=1}^{n} \left( \| y - z_{i,t+1} \|^2 - \| y - z_{i,t+2} \|^2 \right)
\]
(71)
where
\[
\begin{align*}
\Delta_{i,t+1}(\mu_i) &= F_2 \| \mu_i \| \| x_{i,t} - \bar{x}_{i,t} \| + \Delta_{i,t+1}(\mu_i) \\
\Delta_t &= \sum_{j=1}^{n} \sum_{i=1}^{n} F_2 \| \mu_i \| \| x_{i,t} - \bar{x}_{i,t} \|
\end{align*}
\]
To get (55), we now establish upper bounds for
\[
\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(\mu_i) \quad \text{and} \quad \sum_{t=1}^{T} \Delta_t.
\]
(ii-1) Establish an upper bound for \( \sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(\mu_i) \).
Combining (63) and (66)–(68), and choosing \( a = 20 \) yields
\[
\begin{align*}
&\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_{i,t+1}(\mu_i) \leq 4 n F_2 \varepsilon_2 + \sum_{t=1}^{T} 20 n \varepsilon_5 \alpha_t \\
+ &3 F_2 \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \sum_{t=1}^{T} \sum_{i=1}^{n} 20 (F_2 \varepsilon_3 + \varepsilon_4) \alpha_{t}^{\varepsilon_4} \| \mu_i \|^2 \\
- &\sum_{t=1}^{T} \sum_{i=1}^{n} \frac{1}{20 \alpha_{t+1}} \| x_{i,t} \|^2
\end{align*}
(72)
(ii-2) Establish an upper bound for \( \sum_{t=1}^{T} \Delta_t \).
From (39) and (62), for any \( \mu_j \in \mathbb{R}^{m_j} \), and \( a > 0 \), we have
\[
\begin{align*}
&\sum_{t=1}^{T} \sum_{i=1}^{n} \| \mu_j \| \| x_{i,t} - \bar{x}_{i,t} \|
\leq n \varepsilon_2 \sum_{j=1}^{n} \| \mu_j \| + 2 \sum_{t=2}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \| \varepsilon_{i,t-1} \| \| \mu_j \| \\
+ &\frac{n \tau}{1 - \lambda} \sum_{t=1}^{T} \sum_{i=1}^{n} \sum_{j=1}^{n} \| \varepsilon_{i,t} \| \| \mu_j \|
\leq n \varepsilon_2 \sum_{j=1}^{n} \| \mu_j \| \\
+ &\sum_{t=2}^{T} \sum_{i=1}^{n} \left( n a \varepsilon_3 \alpha_t \| \mu_i \|^2 + \frac{n}{\alpha F_2 \alpha_t} \| \varepsilon_{i,t-1} \|^2 \right).
\end{align*}
(73)
Choosing \( a = 20 \) in (73) yields
\[
\begin{align*}
&\sum_{t=1}^{T} \sum_{i=1}^{n} \Delta_i \leq F_2 \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \| + \sum_{t=2}^{T} \sum_{i=1}^{n} \left( 20 F_2 \varepsilon_3 \alpha_t \| \mu_i \|^2 \\
+ &\frac{1}{20 \alpha_t} \| \varepsilon_{i,t-1} \|^2 \right).
\end{align*}
(74)
(ii-3) Prove (55).
Let \( h_{ij} : \mathbb{R}^{m_i} \rightarrow \mathbb{R} \) be a function defined as
\[
\begin{align*}
h_{ij}(\mu_i) &= \mu_i^T \sum_{t=1}^{T} \left[ g_i(x_j,t) \right] + \\
&- \frac{1}{2} \| u_i \|^2 \left( \frac{1}{\gamma_t} + \sum_{t=1}^{n} (\beta_t + \varepsilon_6 \alpha_t) \right).
\end{align*}
\]
(75)
Then, noting (58), (60), (72), (74), and (75), and summing (71) over \( t \in [T] \) gives
\[
\begin{align*}
&\frac{1}{2} \sum_{t=1}^{T} \sum_{i=1}^{n} \left( \frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} \right) \| g_{i,t} - \mu_i \|^2 \\
+ &\frac{1}{n} \sum_{i=1}^{n} \left[ h_{ij}(\mu_i) + n \text{Net-Reg}(\{ x_{i,t} \}, \{ y \}) \right] \\
\leq &\frac{4 n F_2 \varepsilon_2}{a} + \sum_{t=1}^{T} \left( \varepsilon_1 \gamma_t + 20 \varepsilon_5 \alpha_t \right) \\
+ &4 F_2 \varepsilon_2 \sum_{i=1}^{n} \| \mu_i \|^2 + \frac{2 n R(X)^2}{\alpha_{t+1}}.
\end{align*}
\]
(76)
Noting that \( \mu_{t+1} = \frac{\sum_{t=1}^{T} \left[ g_i(x_j,t) \right]}{\sum_{t=1}^{T} (\beta_t + \varepsilon_6 \alpha_t)} \), and substituting \( \mu_i = \mu_{ij} \in \mathbb{R}^{m_i} \) into (75) yields
\[
\begin{align*}
h_{ij}(\mu_{ij}) &= \frac{\| \sum_{t=1}^{T} \left[ g_i(x_j,t) \right] \|^2}{2(\frac{1}{\gamma_t} + \sum_{t=1}^{n} (\beta_t + \varepsilon_6 \alpha_t))}.
\end{align*}
\]
(77)
From \( g_i(x) = \text{col}(g_i(x), \ldots, g_i(x)) \), we have
\[
\begin{align*}
&\sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{t=1}^{T} \left[ g_i(x_j,t) \right] + 2 = \sum_{t=1}^{T} \sum_{i=1}^{n} \left[ g_i(x_j,t) \right] + 2.
\end{align*}
(78)
From the definition of \( \mu_{ij} \) and (6b), we have
\[
\| \mu_{ij} \| \leq \frac{F_1 T}{\gamma_t + \sum_{t=1}^{n} (\beta_t + \varepsilon_6 \alpha_t)}.
\]
(79)
From (6a), we have
\[
- \text{Net-Reg}(\{ x_{i,t} \}, \{ y \}) \leq F_1 T.
\]
(80)
Substituting \( \mu_{ij} = \mu_{ij}^{0} \) into (76), using (77)–(80), and rearranging terms yields (55).

We are now ready to prove Theorem 1. The proof is to substitute the specially designed parameter sequences in (15) into the bounds provided in Lemma 7.
(i) For any constant \( a \in [0, 1] \) and \( T \in \mathbb{N}_+ \), it holds that
\[
\sum_{t=1}^{T} \frac{1}{t^a} \leq \int_1^T \frac{1}{t^a} dt + 1 = \frac{T^{1-a} - a}{1 - a} \leq \frac{T^{1-a}}{1 - a}.
\]
(81)
From (15) and (81), we have
\[
\sum_{t=1}^{T} \left( \varepsilon_1 \gamma_t + 10 \varepsilon_5 \alpha_t \right) \leq \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{10 \varepsilon_5 \alpha_t}{1 - \kappa} T^{1-\kappa}.
\]
(82)
From (15), we have
\[
\begin{align*}
&\frac{1}{\gamma_t} - \frac{1}{\gamma_{t+1}} + \beta_{t+1} = \frac{t}{t^\kappa} - \frac{t + 1}{(t+1)^\kappa} + \frac{1}{t^\kappa} \\
&= \frac{t + 1}{t^\kappa} - \frac{t}{(t+1)^\kappa} > 0.
\end{align*}
\]
(83)
Combining (54), (82), and (83) yields
\[
\text{Net-Reg}\{\{x_{i,t}\}, y[t]\} \leq 4F_2\varepsilon_2 + \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{10\varepsilon_5\alpha_0}{1 - \kappa} T^{1-\kappa} + 4R(X)^2 T^\kappa \frac{\alpha_0}{\alpha_0} + 2R(X) T^\kappa P_T \frac{\alpha_0}{\alpha_0}
\]
which gives (16).

(ii) From (15) and (81), we have
\[
\sum_{t=1}^{T} (\beta_t + \varepsilon_0\alpha_t) \leq \frac{1 + \varepsilon_6\alpha_0}{1 - \kappa} T^{1-\kappa}.
\]
Combining (55), (83), (85), and (86) yields
\[
\left( \frac{1}{n} \sum_{j=1}^{n} \left\| \sum_{t=1}^{T} [g_t(x_{j,t})]_+ \right\| \right)^2 \leq \frac{1}{n} \sum_{j=1}^{n} \left\| \sum_{t=1}^{T} [g_t(x_{j,t})]_+ \right\|^2 
\]
\[
\leq 4n\varepsilon_2 F_1 F_2 T + 2n \left( 1 + \frac{1 + \varepsilon_6\alpha_0}{1 - \kappa} T^{1-\kappa} \right) (F_1 T + \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{20\varepsilon_5\alpha_0}{1 - \kappa} T^{1-\kappa} + 4R(X)^2 T^\kappa \frac{\alpha_0}{\alpha_0}).
\]
Combining (87) and
\[
\sum_{t=1}^{T} \left\| [g_t(x_{j,t})]_+ \right\| \leq \sum_{t=1}^{T} \left\| [g_t(x_{j,t})]_+ \right\|_1
\]
\[
= \left\| \sum_{t=1}^{T} [g_t(x_{j,t})]_+ \right\| \leq \sqrt{n} \left\| \sum_{t=1}^{T} [g_t(x_{j,t})]_+ \right\|
\]
yields (17).

C. Proof of Theorem 2
In addition to the notations defined in the proof of Theorem 1, we also denote \( \varepsilon_T = \left[ \frac{1}{ \int \varepsilon } \right] + 1 \), where \( \cdot \) is the ceiling function.
(i) Under Assumption 3, (50) can be replaced by
\[
f_{i,t}(x_{i,t}) - f_{i,t}(y_t) \leq F_2 \|x_{i,t} - x_{i,t+1}\| - \frac{\mu}{2} \|y_t - x_{i,t}\|^2 + \langle \delta f_{i,t}(x_{i,t}), x_{i,t+1} - y_t \rangle.
\]
Note that compared with (50), (89) has an extra term \(- \frac{\mu}{2} \|y_t - x_{i,t}\|^2\). Then, (58) can be replaced by
\[
\frac{1}{n} \sum_{i=1}^{n} \left( \frac{1}{\alpha_{t+1}} \left( \|y_t - z_{i,t+1}\|^2 - \|y_{t+1} - z_{i,t+2}\|^2 \right) - \mu \|y_t - x_{i,t}\|^2 \right)
\]
\[
= \frac{1}{n} \sum_{i=1}^{n} \left( \frac{1}{\alpha_t} \|y_t - z_{i,t+1}\|^2 - \frac{1}{\alpha_{t+1}} \|y_{t+1} - z_{i,t+2}\|^2 \right) + \left( \frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_t} \right) \|y_t - \sum_{j=1}^{n} [W_{i,j}x_{j,t}]_+ \|^2 - \mu \|y_t - x_{i,t}\|^2
\]
\[
\leq \frac{1}{n} \sum_{i=1}^{n} \left( \frac{1}{\alpha_t} \|y_t - z_{i,t+1}\|^2 - \frac{1}{\alpha_{t+1}} \|y_{t+1} - z_{i,t+2}\|^2 \right) + \left( \frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_t} - \mu \right) \|y_t - x_{i,t}\|^2
\]
(90)
where the inequality holds due to \( \sum_{j=1}^{n} [W_{i,j}x_{j,t}]_+ = 1 \).
When \( t \geq \varepsilon_T \), we have
\[
\frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_t} - \mu = \frac{t + 1}{(t+1) - c} - \frac{t}{t+1 - c} - \mu
\]
\[
< \frac{1}{t+1 - c} - \mu \leq 0.
\]
Similar to the way to get (84), from (21), (90), and (91), we have
\[
\text{Net-Reg}\{\{x_{i,t}\}, \tilde{x}_{\gamma}^{T}\}
\]
\[
\leq 4F_2\varepsilon_2 + \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{10\varepsilon_5}{1 - c} T^{1-c} + \frac{1}{n} \sum_{i=1}^{n} \|y_{t+1} - z_{i,t+2}\|^2
\]
\[
+ \left( \frac{1}{\alpha_{t+1}} - \frac{1}{\alpha_t} - \mu \right) \|y_t - x_{i,t}\|^2
\]
\[
\leq 4F_2\varepsilon_2 + \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{10\varepsilon_5}{1 - c} T^{1-c} + 4(1 + (\varepsilon_T - 1)[1 - \mu]) R(X)^2.
\]
(92)
Noting that \( \kappa \geq 1 - c \) due to \( c \leq 1 - \kappa \), from (92), we have (22).

(ii) Similar to the way to get (87), from (21), (90), and (91), we have
\[
\left( \frac{1}{n} \sum_{j=1}^{n} \left\| \sum_{t=1}^{T} [g_t(x_{j,t})]_+ \right\| \right)^2
\]
\[
\leq 4n\varepsilon_2 F_1 F_2 T + 2n \left( 1 + \frac{1}{1 - \kappa} T^{1-\kappa} + \frac{\varepsilon_6}{1 - c} T^{1-c} \right) (F_1 T + \frac{\varepsilon_1}{\kappa} T^\kappa + \frac{20\varepsilon_5}{1 - c} T^{1-c} + 4(1 + (\varepsilon_T - 1)[1 - \mu]) R(X)^2).
\]
(93)
Noting that \( 1 - \kappa \geq 1 - c \) due to \( c \geq \kappa \), from (88) and (93), we have (23).

Xinlei Yi received the B.S. and M.S. degrees in mathematics from the China University of Geoscience, Wuhan, China, and Fudan University, Shanghai, China, in 2011 and 2014, respectively, and the Ph.D. degree in electrical engineering from the KTH Royal Institute of Technology, Stockholm, Sweden, in 2020.

He is currently a Postdoctoral with the Lab for Information and Decision Systems, Massachusetts Institute of Technology, Cambridge, MA, USA. He was a Postdoctoral with the KTH Royal Institute of Technology until October 2022. His current research interests include online optimization, distributed optimization, and event-triggered control.

Dr. Yi’s doctoral thesis was selected as one of the four finalists for the 2021 European Systems and Control Ph.D. Thesis Award.

Xiuxian Li (Senior Member, IEEE) received the B.S. degree in mathematics and applied mathematics and the M.S. degree in pure mathematics from Shandong University, Jinan, China, in 2009 and 2012, respectively, and the Ph.D. degree in mechanical engineering from the University of Hong Kong, Hong Kong, in 2016.

From 2016 to 2020, he has been a Research Fellow with the School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, and he has also been a Senior Research Associate with the Department of Biomedical Engineering, City University of Hong Kong, Hong Kong, in 2018. He held a Visiting Position with the King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, in September 2019. In 2020, he joined Tongji University, Shanghai, China, where he is currently a Professor. His research interests include distributed control and optimization, game theory, and machine learning, with applications to autonomous vehicles, etc.

Tao Yang (Senior Member, IEEE) received the Ph.D. degree in electrical engineering from Washington State University, Pullman, WA, USA, in 2012.

Between August 2012 and August 2014, he was an ACCESS Postdoctoral Researcher with the ACCESS Linnaeus Center, KTH Royal Institute of Technology, Stockholm, Sweden. He then joined the Pacific Northwest National Laboratory as a Postdoc, and was promoted to Scientist/Engineer II in 2015. He was an Assistant Professor with the Department of Electrical Engineering, University of North Texas, Denton, TX, USA, from 2016 to 2019. He is currently a Professor with the State Key Laboratory of Synthetical Automation for Process Industries, Northeastern University, Shenyang, China. His research interests include industrial artificial intelligence, integrated optimization and control, distributed control and optimization with applications to process industries, cyber physical systems, networked control systems, and multi-agent systems.

Dr. Yang was a recipient of the Ralph E. Powe Junior Faculty Enhancement Award and Best Student Paper awards (as an advisor) of several international conferences. He is currently an Associate Editor for IEEE TRANSACTIONS ON CONTROL SYSTEMS TECHNOLOGY, IEEE TRANSACTIONS ON NEURAL NETWORKS AND LEARNING SYSTEMS, and IEEE/CAA JOURNAL OF AUTOMATICA SINICA.

Lihua Xie (Fellow, IEEE) received the Ph.D. degree in electrical engineering from the University of Newcastle, Callaghan, NSW, Australia, in 1992.

Since 1992, he has been with the School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, where he is currently a Professor and Director with the Center for Advanced Robotics Technology Innovation. He was the Head of Division of Control, Instrumentation and Automation from 2010 to 2014. His research interests include robust control and estimation, networked control systems, multiagent networks, localization, and unmanned systems.

Dr. Xie is currently an Editor-in-Chief for Unmanned Systems and was an Editor of IET Book Series in Control and an Associate Editor of a number of journals including IEEE TRANSACTIONS ON AUTOMATIC CONTROL, Automatica, IEEE TRANSACTIONS ON CONTROL SYSTEMS TECHNOLOGY, IEEE TRANSACTIONS ON CONTROL OF NETWORK SYSTEMS, etc. He was an IEEE Distinguished Lecturer (January 2012–December 2014). He is also a Fellow of IFAC and Academy of Engineering Singapore.

Tianyou Chai (Life Fellow, IEEE) received the Ph.D. degree in control theory and engineering from Northeastern University, Shenyang, China, in 1985.

He became a Professor with Northeastern University in 1988. He is the Founder and Director of the Center of Automation, which became a National Engineering and Technology Research Center and a State Key Laboratory. He is a member of Chinese Academy of Engineering and IFAC Fellow. He was the Director of Department of Information Science of National Natural Science Foundation of China from 2010 to 2018. He has authored/coauthored 230 peer-reviewed international journal papers. His current research interests include modeling, control, optimization, and integrated automation of complex industrial processes.

Dr. Chai’s paper titled Hybrid Intelligent Control for Optimal Operation of Shaft Furnace Roasting Process was selected as one of three best papers for the Control Engineering Practice Paper Prize for 2011–2013. He has developed control technologies with applications to various industrial processes. He was a recipient of five prestigious awards of National Natural Science, National Science and Technology Progress, and National Technological Innovation for his contributions, the 2007 Industry Award for Excellence in Transitional Control Research from IEEE Multiple-conference on Systems and Control, and the 2017 Wook Hyun Kwon Education Award from Asian Control Association.

Karl Henrik Johansson (Fellow, IEEE) received the M.Sc. and Ph.D. degrees in electrical engineering from Lund University, Lund, Sweden, in 1992 and 1997, respectively.

He is currently a Professor with the School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology, Stockholm, Sweden. He has held visiting positions with University of California, Berkeley, Berkeley, CA, USA, Caltech, Pasadena, CA, USA, Nanyang Technological University, Singapore, HKUST Institute of Advanced Studies, Hong Kong, and Norwegian University of Science and Technology, Trondheim, Norway. His research interests include networked control systems, cyber-physical systems, and applications in transportation, energy, and automation.

Dr. Johansson was an Associate Editor for IEEE Control Systems Society Board of Governors, the IFAC Executive Board, and the European Control Association Council. He was a recipient of several best paper awards and other distinctions from IEEE and ACM. He has been awarded Distinguished Professor with the Swedish Research Council and Wallenberg Scholar with the Knut and Alice Wallenberg Foundation. He was also a recipient of the Future Research Leader Award from the Swedish Foundation for Strategic Research and the Triennial Young Author Prize from IFAC. He is currently a Fellow of the Royal Swedish Academy of Engineering Sciences, and he is also the IEEE Control Systems Society Distinguished Lecturer.
