Weak and strong mean-field limits for stochastic Cucker-Smale particle systems

Angelo Rosello

May 2019

Abstract

We consider a particle system with a mean-field-type interaction perturbed by some common and individual noises. When the interacting kernels are sublinear and only locally Lipschitz-continuous, relying on arguments regarding the tightness of random measures in Wasserstein spaces, we are able to construct a weak solution of the corresponding limiting SPDE. This weak convergence can be turned into a strong $L^p(\Omega)$ convergence in a setup where the diffusion coefficient on the environmental noise is bounded. The systems considered include perturbations of the Cucker-Smale model for collective motion.

Keywords: stochastic particle systems, mean-field limit, stochastic partial differential equations, Cucker-Smale model, collective motion.

1 Introduction

1.1 Overview of the model

Flocking, or swarming, is a phenomenon consistently observed in nature where individuals from a population (birds, fish, insects, bacterias...) tend to naturally align their trajectories without the need of a leadership. One of the most commonly studied model which intends to describe this kind of behavior is the Cucker-Smale model, introduced in [9] and [10].

In this model, each individual interacts with the average of the group, in a mean-field-like setting: denoting by \( X_{i,N}, V_{i,N} \in \mathbb{R}^d \) the position and velocity of the \( i \)-th individual, the behavior of the system can be written as

\[
\begin{aligned}
\frac{dX_{i,N}}{dt} &= V_{i,N} dt \\
\frac{dV_{i,N}}{dt} &= \frac{1}{N} \sum_{j=1}^{N} \psi(X_{i,N} - X_{j,N})(V_{j,N} - V_{i,N}) dt
\end{aligned}
\] (1.1)

where the weight function \( \psi : \mathbb{R} \to \mathbb{R}^+ \) is even and bounded, typically of the form

\[
\psi(x - y) = \frac{\lambda}{(1 + |x - y|^2)^\gamma}, \quad \lambda, \gamma > 0.
\]

In order to take into account unpredictable phenomena of different natures, it is rather natural to perturb this deterministic model with some random noise. While presenting new models, we choose to introduce this noise in the Stratonovich form, since it is more physically relevant. In [5], where the flocking phenomenon is studied in a variety of different stochastic Cucker-Smale models, three different kinds of perturbations are identified.

The first one considers the degree of freedom of each individual by adding some independent noise, dragged by a brownian motion \( B_i \), to each of them:

\[
\frac{dV_{i,N}}{dt} = \frac{1}{N} \sum_{j=1}^{N} \psi(X_{i,N} - X_{j,N})(V_{j,N} - V_{i,N}) dt + \sigma(X_{i,N}, V_{i,N}) \circ dB_i.
\] (1.2)

This setting typically appears in the propagation of chaos framework. The flocking behavior for (1.2) has been studied in [15]. The mean-field limit as \( N \) goes to infinity is considered in [3], in the case of a constant diffusion coefficient \( \sigma(x, v) = \sqrt{D} I_d \), and more recently in [7] for \( \sigma(x, v) = R(v) \) a "truncation function" of the speed.

Another kind of perturbation might emerge from the environment in which the individuals evolve. In this case, we add some common noise dragged by a Wiener process \( dW = \sum_k \sigma_k dW^k \):

\[
\frac{dV_{i,N}}{dt} = \frac{1}{N} \sum_{j=1}^{N} \psi(X_{i,N} - X_{j,N})(V_{j,N} - V_{i,N}) dt + \sum_k \sigma_k(X_{i,N}, V_{i,N}) \circ dW^k.
\] (1.3)

A version of (1.3), with a diffusion coefficient of the form \( \sigma(x, v) = D(v - v_e) \) for some constant \( v_e \in \mathbb{R}^d \), is studied in [1].

Lastly, one may consider that the weight function \( \psi \) modeling the interaction between individuals is perturbed into \( \tilde{\psi} = \psi + d\xi \), where \( \xi \) is some space-dependent Wiener process given by \( d\xi = \sum_k \phi_k d\beta^k \), leading to

\[
\frac{dV_{i,N}}{dt} = \frac{1}{N} \sum_{j=1}^{N} \psi(X_{i,N} - X_{j,N})(V_{j,N} - V_{i,N}) dt + \frac{1}{N} \sum_{k=1}^{N} \sum_k \phi_k(X_{i,N} - X_{j,N})(V_{i,N} - V_{i,N}) \circ d\beta^k.
\] (1.4)
The mean-field limit and flocking for (1.4) is looked upon in [6] and more recently in [14] in the particular case where the perturbation $\xi$ does not depend on $x$: $d\xi = \sqrt{2\sigma}d\beta_t$.

In this paper, we shall not examine the question of flocking, but instead we focus on the mean-field limit of these particle systems. Namely, we intend to extend the results mentioned above by studying the behavior of the empirical measure

$$\mu^N_t = \frac{1}{N} \sum_{i=1}^N \delta_{(X_{i,N},V_{i,N})} \in \mathcal{P}(\mathbb{R}^d \times \mathbb{R}^d)$$

as $N$ goes to infinity, for general stochastic Cucker-Smale model of the form (1.2), (1.3) or (1.4) (or combinations of these models). Let us keep the notions of convergence a little vague for a moment, in order to give a quick overview of the results to come: we will show for instance that, for (1.4), under the assumptions

$$\sum_k \|\phi_k\|_\infty^2 < \infty, \quad \sum_k \|\phi_k\|_{lip}^2 < \infty, \quad (1.5)$$

where $\|\phi\|_{lip} = \sup_{x\neq y} \frac{\|\phi(x) - \phi(y)\|}{|x-y|}$, provided that $\mu^N_0 \to \mu_0$, the (random) empirical measure $\mu^N_t$ converges in law, up to a subsequence, to some $\mu_t$ which is a weak solution of the expected limiting stochastic PDE

$$d\mu_t + v \cdot \nabla \mu_t dt + \nabla_v \cdot (F[\mu_t]d\mu_t) dt + \sum_k \nabla_v \cdot (F_k[\mu_t]d\mu_t) \circ d\beta_t^k = 0, \quad (1.6)$$

with

$$F[\mu](x,v) = \int \psi(x-y)(w-v)d\mu(y,w), \quad F_k[\mu](x,v) = \int \phi_k(x-y)(w-v)d\mu(y,w).$$

Regarding the flocking phenomenon, the method developed in [6] could in fact be extended to the model (1.6). Given a solution $\mu = (\mu_t)_{t\geq 0}$ of (1.6), the average velocity $\bar{v}_t = \int v d\mu_t$ is conserved over time. Assuming that

$$\psi_m := \min_x \psi(x) > 0, \quad \sum_k \|\phi_k\|_\infty^2 < \infty$$

and denoting

$$E_t = \int_{\mathbb{R}^{2d}} |v - \bar{v}_t|^2 d\mu_t(x,v)$$

calculations easily lead to

$$\frac{d}{dt} \mathbb{E}[E_t] \leq -2 \left( \psi_m - 4 \sum_k \|\phi_k\|_\infty^2 \right) \mathbb{E}[E_t].$$

Therefore, under the condition $\psi_m > 4 \sum_k \|\phi_k\|_\infty^2$, the model (1.6) exhibits a flocking behavior in the sense that $\mathbb{E}[E_t] \to 0$ exponentially fast as $t$ goes to infinity.

Under the same assumptions (1.5), the strong $L^p(\Omega)$ mean-field convergence $\mu^N_t \to \mu_t$ is obtained (for the whole sequence) if we consider "truncated velocities" in the perturbative term, that is a model given by

$$dV^{i,N}_t = \frac{1}{N} \sum_{j=1}^N \psi(X^{i,N}_t - X^{j,N}_t)(V^{j,N}_t - V^{i,N}_t)dt + \frac{1}{N} \sum_{j=1}^N \sum_k \phi_k(X^{i,N}_t - X^{j,N}_t)R(V^{j,N}_t - V^{i,N}_t) \circ d\beta_t^k \quad (1.7)$$
where $\mathcal{R} : \mathbb{R}^{d} \to \mathbb{R}^{d}$ is smooth and compactly-supported, similarly to the case considered in [7]. We are in fact allowed slightly more general truncation functions, as will be detailed later on in section 3.2.

Let $(\Omega, \mathcal{F}, (\mathcal{F}_{t})_{t \geq 0}, \mathbb{P})$ be a filtered probability space, and let $\beta, (B^{i})_{i \geq 1}$ be independent, respectively $\mathbb{R}$-valued and $\mathbb{R}^{d}$-valued $(\mathcal{F}_{t})$-Brownian motions on $\Omega$. Throughout the rest of this paper, we extend our study to a stochastic interacting particle system in $\mathbb{R}^{d}$ of the general mean-field form

$$dX_{t}^{i,N} = B[\mu_{t}^{N}](X_{t}^{i,N})dt + C[\mu_{t}^{N}](X_{t}^{i,N}) \circ dB_{t}^{i} + \sigma(X_{t}^{i,N}) \circ dB_{t}^{i},$$

where

$$\mu_{t}^{N} = \frac{1}{N} \sum_{i=1}^{N} \delta_{X_{t}^{i,N}}, \quad B[\mu](x) = \int b(x, y)d\mu(y), \quad C[\mu](x) = \int c(x, y)d\mu(y).$$

(1.9)

for some coefficients $b, c : \mathbb{R}^{d} \times \mathbb{R}^{d} \to \mathbb{R}^{d}$ and $\sigma : \mathbb{R}^{d} \to \mathbb{R}^{d \times d}$. The particles in (1.8) are subject to two noises of different nature: some individual noise dragged by $B_{t}^{i}$ and some common noise dragged by $\beta_{t}$. The case $c(x, y) = c(x)$ corresponds to a noisy environment (as in (1.3)) whereas the case $c(x, y) = c(x - y)$ corresponds to a noisy interaction (as in (1.4)).

For simplicity purposes, from this point on we choose to only consider a "one-dimensional" common noise $c(x, y) \circ dB_{t}^{i}$. It may of course be replaced with a more general $\sum_{k=1}^{\infty} c_{k}(x, y) \circ dB_{t}^{k}$. The results presented in this paper will still hold, provided essentially that the assumptions made here on $c$ are satisfied by all $c_{k}$, with constants which are square-summable over $k$, as suggested in (1.5).

The mean-field limit of (1.8) is well known and established when $b, c$ and $\sigma$ are globally Lipschitz-continuous (see e.g [8]). Of course, in this study we would like to include Cucker-Smale perturbations of the form (1.2), (1.3) and (1.4), which corresponds to $Z_{t}^{i,N} = (X_{t}^{i,N}, V_{t}^{i,N})$ satisfying (1.8) in $\mathbb{R}^{2d}$ with coefficients of the form

$$b((x, v); (y, w)) = \left( \begin{array}{c} v \\ \psi(x - y)(w - v) \end{array} \right), \quad c((x, v); (y, w)) = \left( \begin{array}{c} 0 \\ \phi(x - y)(w - v) \end{array} \right)$$

(1.10)

which, when $\psi, \phi$ are globally Lipschitz-continuous, are only locally Lipschitz-continuous.

In view of usual stochastic mean-field results, it is natural to expect that the limiting equation for the empirical measure $\mu_{t}^{N}$ associated to (1.8) as $N$ goes to infinity is given by

$$d\mu_{t} + \nabla \cdot (B[\mu_{t}]\mu_{t})dt + \nabla \cdot (C[\mu_{t}]\mu_{t}) \circ dB_{t} + \frac{1}{2} \nabla \cdot (\text{Tr}(\nabla \sigma \sigma^{*})\mu_{t})dt = \frac{1}{2} \nabla \cdot (\nabla \cdot (\sigma \sigma^{*}\mu_{t}))dt$$

(1.11)

where we have used the slight abuse of notation:

$$\left( \text{Tr}(\nabla \sigma \sigma^{*}) \right)_{i} = \text{Tr}(\nabla \sigma_{i}\sigma^{*}) = \sum_{k,l=1}^{d} (\partial_{k}\sigma_{i,l})\sigma_{k,l}. \quad (1.12)$$

Due to the driving noise $\beta_{t}$ which is common to all particles, (1.11) is an SPDE, so that the limiting measure $(\mu_{t})_{t \geq 0}$ is still a stochastic process. The individual noises $\sigma dB_{t}^{i}$ are expected to average into the elliptic operator $\frac{1}{2} \nabla \cdot (\nabla \cdot (\sigma \sigma^{*})).$ The first order operator $\frac{1}{2} \nabla \cdot (\text{Tr}(\nabla \sigma \sigma^{*})).$
only results from the correction from Stratonovich to Itô integration. In the particular case \( \sigma(x) \equiv \sigma Id \), we are simply left with

\[
d\mu_t + \nabla \cdot (B[\mu_t] \mu_t) dt + \nabla \cdot (C[\mu_t] \mu_t) \circ d\beta_t = \frac{\sigma^2}{2}(\Delta \mu_t) dt.
\]

Note that the system (1.8) and the SPDE (1.11) have only been given in the heuristical Stratonovich form. In section 1.3, we shall determine the corresponding Itô forms and derive a proper definition for solutions of (1.8) and particularly (1.11) (see Definition 1.2).

1.2 Main results

In the rest of this paper, \( \mathcal{P}(E) \) denotes the set of probability measures on some space \( E \).

The results presented here along with their proofs involve some considerations regarding Wasserstein spaces \( \mathcal{P}_p(E) \).

**Definition 1.1.** Given \((E, \|\cdot\|)\) a normed polish space and \( p \geq 1 \), the \( p \)-th-Wasserstein space \( \mathcal{P}_p(E) = \{ \mu \in \mathcal{P}(E), \int_{x \in E} \|x\|^p d\mu(x) < \infty \} \) is equipped with the distance

\[
W_p[\mu, \nu] = \left( \inf_{\pi \in \Pi(\mu, \nu)} \int_{x^1, x^2 \in E} \|x^1 - x^2\|^p d\pi(x^1, x^2) \right)^{1/p},
\]

where

\[
\Pi(\mu, \nu) = \left\{ \pi \in \mathcal{P}(E^2), \int_{x^2 \in E} \pi(., dx^2) = \mu \text{ and } \int_{x^1 \in E} \pi(dx^1, .) = \nu \right\}.
\]

In the rest of this paper, we shall sometimes use the notation \( A(z) \lesssim B(z) \) to signify that there exists a constant \( C > 0 \) independent of the variable \( z \) considered such that \( A(z) \leq CB(z) \) for all \( z \).

Defining the Stratonovich corrective terms (see section 1.3)

\[
s_1(x, y, z) = \frac{1}{2} \nabla x c(x, y)c(x, z) + \nabla y c(x, y)c(y, z),
\]

\[
S_2(x) = \text{Tr}((\nabla \sigma_i)^* \sigma^*) = \sum_{k,l=1}^d (\partial_k \sigma_{i,l}) \sigma_{k,l},
\]

we shall first make the following assumptions on the coefficients of (1.8):

**Assumption 1** (Sublinearity).

\[
|b(x, y)| \lesssim 1 + |x| + |y|, \quad |c(x, y)| \lesssim 1 + |x| + |y|, \quad |
\sigma(x)| \lesssim 1 + |x|
\]

\[
|s_1(x, y, z)| \lesssim 1 + |x| + |y| + |z|, \quad |S_2(x)| \lesssim 1 + |x|.
\]

**Assumption 2** (Locally Lipschitz).

\[
b, c, \sigma, \nabla c, \nabla \sigma \text{ are locally Lipschitz-continuous.}
\]

In this rather general setup, the local Lipschitz-continuity alone is not enough to ensure 'standard' estimates of the form

\[
\mathbb{E}\left[ W_2^2[\mu_t^N, \mu_t^M] \right] \leq CW_2^2[\mu_0^N, \mu_0^M]
\]

and we are not able to establish the "strong" convergence of the particle system. Instead, we rely on compactness arguments to prove the following weak mean-field limit result.
Theorem 1. Let $T > 0$ and $C := C([0, T]; \mathbb{R}^d)$. Suppose that Assumptions 1 and 2 are satisfied. Let $\mu_0 \in \mathcal{P}(\mathbb{R}^d)$ such that
\[
\int |x|^{2+\delta} d\mu_0(x) < \infty \text{ for some } \delta > 0.
\]
Let $(X_t^{i,N})_{i=1}^{N} \geq 0$ be a solution of (1.8) and $\mu^N \in \mathcal{P}(C)$ the associated empirical measure. Provided that
\[
\mu_0^N \to \mu_0 \text{ in } \mathcal{P}_2(\mathbb{R}^d) \text{ and } \sup N \int |x|^{2+\delta} d\mu_0^N(x) < \infty,
\]
there exists a subsequence $(\mu^N_{N'})$ such that
\[
\mu^N_{N'} \to \mu \text{ in law, in } \mathcal{P}_2(C)
\]
and $\mu$ is a weak solution (in the probabilistic sense) of (1.11): there exists some other probability space $(\Omega, \bar{F})$ equipped with a brownian motion $\bar{\beta}$ such that $\mu$ satisfies the assumptions of Definition 1.2 below on $\Omega$.

This weak convergence can be strengthened into a strong convergence for compactly-supported initial measures, under some more restrictive assumptions on the coefficients.

Let us suppose for simplicity

Assumption 3 (Common noise only).
\[
\sigma = 0.
\]

In this case, the limiting SPDE (1.11) becomes a stochastic conservation equation:
\[
d\mu_t + \nabla \cdot (B[\mu_t] \mu_t) dt + \nabla \cdot (C[\mu_t] \mu_t) \circ d\beta_t = 0. \tag{1.15}
\]

A solution of (1.15) is expected to be "of the transport form" $\mu = (X^\mu)^* \mu_0$, i.e $\mu$ is given by the push-forward measure of the initial data by the (non-linear) stochastic characteristics
\[
\left\{ \begin{array}{l}
dX_t^\mu(x) = B[\mu_t](X_t^\mu(x)) dt + C[\mu_t](X_t^\mu(x)) \circ d\beta_t, \\
X_0^\mu(x) = x \in \mathbb{R}^d.
\end{array} \right.
\]

A precise statement on measures of the transport form is made in Definition 3.1. Let us make some additional assumptions on the coefficients:

Assumption 4 (Sublinear drift, bounded diffusion coefficient).
\[
|b(x, y)| \lesssim 1 + |x| + |y|,
|s_1(x, y, z) - s_1(x', y', z')| \lesssim 1 + |x| + |y| + |z|,
|c(x, y)| \lesssim 1,
\]

Assumption 5 (Growth of the local Lipschitz constants). For some $\theta \in [0, 1)$,
\[
|b(x, y) - b(x', y')| \lesssim \left( 1 + |x|^{2\theta} + |y|^{2\theta} + |x'|^{2\theta} + |y'|^{2\theta} \right) \left( |x - x'| + |y - y'| \right),
|s_1(x, y, z) - s_1(x', y', z')| \lesssim \left( 1 + |x|^{2\theta} + |y|^{2\theta} + |z|^{2\theta} + |x'|^{2\theta} + |y'|^{2\theta} + |z'|^{2\theta} \right) \left( |x - x'| + |y - y'| + |z - z'| \right),
|c(x, y) - c(x', y')| \lesssim \left( 1 + |x|^\theta + |y|^\theta + |x'|^\theta + |y'|^\theta \right) \left( |x - x'| + |y - y'| \right).
\]

Theorem 2. Let $T > 0$, $p \geq 2$ and $C := C([0, T]; \mathbb{R}^d)$.

Suppose that Assumptions 3, 4 and 5 are satisfied. With the same notations as before, provided that $\mu_0^N$ is uniformly supported in some compact set $K \subset \mathbb{R}^d$ and $\mu_0^N \to \mu_0$ in $\mathcal{P}_p(\mathbb{R}^d)$, we have the convergence
\[
\mu^N \to \mu \text{ in } L^p(\Omega; \mathcal{P}_p(C)),
\]
where $\mu = (\mu_t)_{t \in [0, T]}$ is the unique solution of the transport form of (1.15), in the sense of Definitions 1.2 and 3.1 below.
1.3 Itô form

Let us now determine the proper Itô form expressions of (1.8) and (1.11). Itô’s formula gives

\[ d \left[ C[\mu_t^N](X_t^{i,N}) \right] = \frac{1}{N} \sum_j d \left[ c(X_t^{i,N}, X_t^{j,N}) \right] = \left( \frac{1}{N} \sum_j \nabla_x c(X_t^{i,N}, X_t^{j,N}) C[\mu_t^N](X_t^{i,N}) + \nabla_y c(X_t^{i,N}, X_t^{j,N}) C[\mu_t^N](X_t^{j,N}) \right) d\beta_t \]

\[ + dV_t^{i,j} + dM_t^{i,j} \]

where \( V_t^{i,j} \) is a process with bounded variation and

\[ dM_t^{i,j} = \frac{1}{N} \sum_j \left( \nabla_x c(X_t^{i,N}, X_t^{j,N}) \sigma(X_t^{i,N}) dB_t^i + \nabla_y c(X_t^{i,N}, X_t^{j,N}) \sigma(X_t^{j,N}) dB_t^j \right). \]

It follows that the correction from Stratonovich to Itô is given by

\[ C[\mu_t^N](X_t^{i,N}) \circ d\beta_t = C[\mu_t^N](X_t^{i,N}) d\beta_t + S_1[\mu_t^N](X_t^{i,N}) dt \]

with

\[ S_1[\mu](x) = \int \int s_1(x, y, z) d\mu(y)d\mu(z) \quad (1.16) \]

where

\[ s_1(x, y, z) = \frac{1}{2} \nabla_x c(x, y)c(x, z) + \nabla_y c(x, y)c(y, z) \]

as defined in (1.13). Similarly, the correction for the individual noise is given by

\[ \sigma(X_t^{i,N}) \circ dB_t^i = \sigma(X_t^{i,N}) dB_t^i + S_2(X_t^{i,N}) dt \]

with

\[ S_2(x) = \frac{1}{2} \text{Tr}(\nabla \sigma(x) \sigma^*(x)) \]

as defined in (1.14). We may now rewrite the particle system (1.8) as

\[ dX_t^{i,N} = \left( B[\mu_t^N](X_t^{i,N}) + S[\mu_t^N](X_t^{i,N}) \right) dt + C[\mu_t^N](X_t^{i,N}) d\beta_t + \sigma(X_t^{i,N}) dB_t^i, \quad (1.17) \]

where

\[ S[\mu](x) = S_1[\mu](x) + S_2(x) \text{ is defined in } (1.16) \text{ and } (1.14). \]

As for the SPDE (1.11), it is to be understood in the following weak sense: for any \( \psi \in C_c^2(\mathbb{R}^d) \),

\[ d(\psi, \mu_t) = \langle (B[\mu_t] + \frac{1}{2} \text{Tr}(\nabla \sigma^*)) \cdot \nabla \psi, \mu_t \rangle dt + \langle C[\mu_t] \cdot \nabla \psi, \mu_t \rangle \circ d\beta_t + \frac{1}{2} \langle \text{Tr}(\sigma(\nabla^2 \psi) \sigma^*), \mu_t \rangle dt. \]

Let us determine the correction corresponding to the Stratonovich term. We have

\[ d \left[ \langle C[\mu_t] \cdot \nabla \psi, \mu_t \rangle \right] = \langle C[\mu_t] \cdot \nabla \psi, d\mu_t \rangle + \langle d \left[ C[\mu_t] \cdot \nabla \psi \right], \mu_t \rangle. \]
On one hand,
\[
\langle C[\mu_t] \cdot \nabla \psi, d\mu_t \rangle = \langle C[\mu_t] \cdot \nabla (C[\mu_t] \cdot \nabla \psi), \mu_t \rangle d\beta_t + dV_t^{(1)} \\
= \left( \langle \nabla C[\mu_t] C[\mu_t] \cdot \nabla \psi, \mu_t \rangle + \langle \nabla^2 \psi \cdot C[\mu_t]^\otimes2, \mu_t \rangle \right) d\beta_t + dV_t^{(1)}
\]
where \( V^{(1)} \) is a process with bounded variation. On the other hand,
\[
C[\mu_t](x) \cdot \nabla \psi(x) = \int \phi(y) d\mu_t(y) = \langle \phi, \mu_t \rangle \text{ with } \phi(y) = c(x, y) \cdot \nabla \psi(x)
\]
so that
\[
d\left[ C[\mu_t] \cdot \nabla \psi \right](x) = d\langle \phi, \mu_t \rangle = \langle C[\mu_t] \cdot \nabla \phi, \mu_t \rangle d\beta_t + dV_t^{(2)}(x)
\]
\[
= \left( \left( \int \nabla_y c(x, y) C[\mu_t](y) d\mu_t(y) \right) \cdot \nabla \psi(x) \right) d\beta_t + dV_t^{(2)}(x)
\]
where \( V^{(2)}(x) \) is a process with bounded variation. Combining both expressions, we are led to
\[
d\left[ \langle C[\mu_t] \cdot \nabla \psi, \mu_t \rangle \right] = \langle 2S_1[\mu_t] \cdot \nabla \psi + \nabla^2 \psi \cdot (C[\mu_t]^\otimes2), \mu_t \rangle d\beta_t + dU_t
\]
where \( U_t = \int_0^t \left( dV_s^{(1)} + dV_s^{(2)}, \mu_s \right) \) is a process with bounded variation. The correction is therefore given by
\[
\langle C[\mu_t] \cdot \nabla \psi, \mu_t \rangle \circ d\beta_t = \langle C[\mu_t] \cdot \nabla \psi, \mu_t \rangle d\beta_t + \left( \langle S_1[\mu_t] \cdot \nabla \psi, \mu_t \rangle + \frac{1}{2} \langle \nabla^2 \psi \cdot (C[\mu_t]^\otimes2), \mu_t \rangle \right) dt.
\]
Consequently, the Itô form corresponding to the SPDE (1.11) is exactly
\[
d\mu_t + \nabla \cdot \left( (B[\mu_t] + S[\mu_t]) \mu_t \right) dt + \nabla \cdot (C[\mu_t] \mu_t) d\beta_t = \frac{1}{2} \nabla \cdot \left( (\sigma \sigma^* + C[\mu_t] C[\mu_t]^*) \mu_t \right) dt \\
\quad \tag{1.18}
\]
with \( S[\mu] \) as in (1.17). This allows us to precisely define the notion of solution for (1.11).

**Definition 1.2.** Let \((\Omega, \mathcal{F}, (\mathcal{F}_t, \mathbb{P})\) be a filtered probability space equipped with an \((\mathcal{F}_t)-\text{brownian motion } \beta\). Let \( \mu_0 \in \mathcal{P}(\mathbb{R}^d) \).

A measure-valued process \( \mu = (\mu_t)_{t \in [0, T]} : \Omega \to \mathcal{P}(\mathbb{R}^d)^{[0, T]} \) is said to be a solution of the SPDE (1.11) (or equivalently (1.18)) with initial value \( \mu_0 \) when for all \( \psi \in C_c^2(\mathbb{R}^d) \), the process \( (\langle \psi, \mu_t \rangle)_{t \in [0, T]} \) is adapted with a continuous version and satisfies
\[
(\psi, \mu_t) = \langle \psi, \mu_0 \rangle + \int_0^t \left( \langle B[\mu_s] + S[\mu_s] \rangle \cdot \nabla \psi + \mathcal{A}[\mu_s] \psi, \mu_s \rangle ds + \int_0^t \langle C[\mu_s] \cdot \nabla \psi, \mu_s \rangle d\beta_s, \tag{1.19}
\]
where \( S[\mu] \) is defined in (1.17) and the second order operator \( \mathcal{A}[\mu] \) is given by
\[
\mathcal{A}[\mu] \psi = \frac{1}{2} \sum_{i,j,k} \left( \sum_k \sigma_{i,k} \sigma_{j,k} + C_{i}[\mu] C_{j}[\mu] \right) \partial_{i,j,k}^2 \psi. \tag{1.20}
\]

**Remark 1.1.** Comparing the particle system (1.17) and the SPDE (1.18) expressed in Itô form, we see that the correction from Stratonovich to Itô integration adds some "virtual" interaction kernel \( S[\mu] \) to the system. On the SPDE (1.18), it additionally results in the operator \( \mathcal{A}[\mu] \) which is of order 2 and consequently is not "visible" on the particle system (1.17).
2 Weak mean-field convergence

2.1 Assumptions on the coefficients

In the entirety of section 2, we shall assume that Assumptions 1 and 2 are satisfied.

Assumption 2 guarantees that the coefficients of the SDE system expressed in Itô form (2.3) naturally guarantees some moment estimates for the solutions of (1.8) and (2.1) are satisfied in the classical "globally-Lipschitz" setup where immediately results in 1.8 and 2 are satisfied.

Most importantly, we are indeed allowed to consider coefficients with the Cucker-Smale form: let $b$ and $c$ be given by (1.10). Assuming that $\psi$, $\phi$ are bounded and locally Lipschitz-continuous, $b$ and $c$ are clearly sublinear. Moreover, a simple calculation gives, with $z_i = (x_i, v_i)$,

$$s_1(z_1, z_2, z_2) = \left( \begin{array}{c} 0 \\ -\phi(x_1 - x_2)\phi(x_1 - x_3)(v_3 - v_1) + \phi(x_1 - x_2)\phi(x_2 - x_3)(v_3 - v_2) \end{array} \right)$$

which is sublinear as well.

2.2 Estimates for the particle system

Firstly, Assumption 1 naturally guarantees some moment estimates for the solutions of (1.8).

**Proposition 2.1** (Moment estimates, global existence).

Let $T > 0$, $q \geq 2$ and $\mu_0^N = \frac{1}{N} \sum_i \delta_{X_i^0}$ be such that $\int |x|^q d\mu_0^N(x) < \infty$. Then the SDE system (1.8) (or equivalently (1.17)) has a unique solution defined on $[0, T]$, which satisfies,

$$\mathbb{E} \left[ \sup_{t \in [0,T]} \int |x|^q d\mu_t^N(x) \right] \lesssim \int |x|^q d\mu_0^N(x) \quad (2.2)$$

and for all $i \in \{1, \ldots, N\}$,

$$\mathbb{E} \left[ \sup_{t \in [0,T]} |X_t^{i,N}|^q \right] \lesssim \left( |X_0^{i,N}|^q + \int |x|^q d\mu_0^N(x) \right). \quad (2.3)$$

The constants involved in $\lesssim$ depend on $T$ and $q$ only.

**Proof.** The assumptions guarantee that the coefficients of the SDE (1.17) are locally Lipschitz-continuous, which provides the local existence and uniqueness of the solution. To simplify the notation, we shall consider that all stochastic integrals are well defined: for a more rigorous framework, one should consider the solution of the truncated equations with a suitable stopping time; classically, the estimate (2.3) (uniform on the truncation) then ensures that the solution is globally defined. Using (2.1), one can write

$$|X_t^{i,N}|^q \lesssim |X_0^{i,N}|^q + \int_0^t (|B[\mu_s^N](X_s^{i,N})|^q + |S[\mu_s^N](X_s^{i,N})|^q)ds + |M_t^{i,q}|$$

$$\lesssim |X_0^{i,N}|^q + \int_0^t |X_s^{i,N}|^q + \int |x|^q d\mu_s^N ds + |M_t^{i,q}| \quad (2.4)$$
where \( M_i^t = \int_0^t C[\mu_s^N](X_s^{i,N})d\beta_s + \int_0^t \sigma(X_s^{i,N})dB^i_s \). Taking the mean over \( i \), and letting \( |X_t|^q = \int |x|^q d\mu_t^N \) we are led to
\[
|X_t|^q \lesssim |X_0|^q + \int_0^t |X_s|^q ds + \frac{1}{N} \sum_i |M_i^t|^q
\]
and therefore,
\[
\sup_{\sigma \in [0,t]} |X_{\sigma}|^q \lesssim |X_0|^q + \int_0^t \sup_{\sigma \in [0,s]} |X_{\sigma}|^q ds + \frac{1}{N} \sum_i \sup_{\sigma \in [0,t]} |M_i^t|^q. \tag{2.5}
\]

Burkholder-Davis-Gundy’s inequality from [4] states that \( \mathbb{E}(|M_t|^q)^\frac{q}{2} \lesssim \mathbb{E} \left( \left[ M_t \right]^{q/2} \right) \).

Using (2.1),
\[
[M_t]^{q/2} \lesssim \int_0^t |X_s^{i,N}|^q + |X_s|^q ds.
\]

hence \( [M_t]^{q/2} \lesssim \int_0^t |X_s^{i,N}|^q + |X_s|^q ds \). Coming back to (2.5),
\[
\mathbb{E} \sup_{\sigma \in [0,t]} |X_{\sigma}|^q \lesssim |X_0|^q + \int_0^t \mathbb{E} \sup_{\sigma \in [0,s]} |X_{\sigma}|^q ds. \tag{2.6}
\]

and we use Grönwall’s Lemma to get the first estimate of Proposition 2.1. We can now get back to (2.4) to get
\[
\sup_{\sigma \in [0,t]} |X_t^{i,N}|^q \lesssim |X_0^{i,N}|^q + \int_0^t \sup_{\sigma \in [0,s]} |X_s^{i,N}|^q ds + \sup_{\sigma \in [0,T]} |X_{\sigma}|^q + \sup_{\sigma \in [0,t]} |M_i^t|^q.
\]

Using the previously established estimate and Burkholder-Davis-Gundy’s inequality once again,
\[
\mathbb{E} \left[ \sup_{\sigma \in [0,t]} |X_t^{i,N}|^q \right] \lesssim \left( |X_0^{i,N}|^q + |X_0|^q \right) + \int_0^t \mathbb{E} \left[ \sup_{\sigma \in [0,s]} |X_s^{i,N}|^q \right] ds
\]
and we may apply Grönwall’s Lemma to obtain the second estimate of Proposition 2.1. \( \square \)

**Remark 2.1.** Given some \( \psi \in C^2(\mathbb{R}^d) \) with \( |\nabla \psi|, |\nabla^2 \psi| \lesssim 1 \), Itô’s formula gives
\[
d\psi(X_t^{i,N}) = \nabla \psi(X_t^{i,N}) \cdot (B[\mu_t^N] + S[\mu_t^N]) d\beta_t + \nabla \psi(X_t^{i,N}) \cdot C[\mu_t^N] d\beta_t + \nabla \psi(X_t^{i,N}) \cdot \sigma(X_t^{i,N}) dB_t + A[\mu_t^N] d\beta_t,
\]
hence taking the mean in \( i \in \{1, \ldots, N\} \) we are led to
\[
\langle \psi, \mu_t^N \rangle = \langle \psi, \mu_0^N \rangle + \int_0^t (\langle B[\mu_s^N] + S[\mu_s^N] \rangle \cdot \nabla \psi + A[\mu_s^N] \cdot \nabla \psi, \mu_s^N \rangle ds + \int_0^t \langle C[\mu_s^N] \cdot \nabla \psi, \mu_s^N \rangle dB_t
\]
\[
+ \frac{1}{N} \sum_i \int_0^t \langle \nabla \psi(X_t^{i,N}) \cdot (\sigma(X_t^{i,N}) dB_t^i \rangle. \tag{2.7}
\]

Given the bounds on \( \mathbb{E} \int |x|^2 d\mu_t^N(x) \), it is easy to see that the stochastic integrals involved are continuous martingales. Aside from the last term, which is expected to vanish as \( N \) goes to infinity, this is exactly the SPDE (1.18).

Let us now establish some estimates regarding the regularity of solutions of (1.8).
The following estimate holds uniformly for the Lévy-Prokhorov metric, which also makes it a polish space (one may refer to topology of the weak convergence. More precisely, we shall consider that

Proposition 2.3.

For a sequence $E$

Definition 2.1.

The following result (mentioned e.g. in [16] p178) establishes a link between the relative compactness in law of $\mu$ and the tightness of its intensity measure $I(\mu)$.

Proposition 2.3.

For a sequence $\mu^N_{N \geq 1}$ of random measures on $E$, the two following statements are equivalent.

\[ \frac{1}{N} \sum_i |X_t^{i,N} - X_s^{i,N}|^q < \left( \int |x|^q d\mu_0^N \right)|t-s|^{q/2}. \]

The constant involved in $\leq$ depends on $T$ and $q$ only.

Proof. Again, one can write

\[ |X_t^{i,N} - X_s^{i,N}|^q \lesssim \int_s^t (|B[\mu^N_\sigma]| + |S[\mu^N_\sigma]|)(X_{i,N}^{s,N})d\sigma|^{q} + |M_t^i - M_s^i|^q \]

hence using the estimates from Proposition 2.1,

\[ \frac{1}{N} \sum_i |X_t^{i,N} - X_s^{i,N}|^q \lesssim |t-s|^q \int |x|^q d\mu_0^N + \frac{1}{N} \sum_i |M_t^i - M_s^i|^q. \]

Burkholder-Davis-Gundy’s inequality gives

\[ \mathbb{E}|M_t^i - M_s^i|^q \lesssim \mathbb{E} \left[ \left[ |M|^q \right]_t - \left[ |M|^q \right]_s \right]^{q/2} \]

\[ \lesssim \mathbb{E} \left[ \int_s^t \left| X_{\sigma}^{i,N} \right|^q + \left| X_{\sigma}^{i,N} \right| d\sigma \right]^{q/2} \lesssim |t-s|^{q/2 - 1} \int_s^t \mathbb{E} \left[ |X_{\sigma}^{i,N}|^q \right] d\sigma \]

since $q/2 \geq 1$, hence

\[ \frac{1}{N} \sum_i |M_t^i - M_s^i|^q \lesssim |t-s|^{q/2 - 1} \int_s^t \mathbb{E} \left[ \int |x|^q d\mu_\sigma^N \right] d\sigma \lesssim |t-s|^{q/2} \int |x|^q d\mu_0^N. \]

\[ \square \]

2.3 Tightness of measure-valued random variables

In this subsection, we state general results regarding the tightness of random measures, which we shall later apply in our special case.

Let $E$ be a polish space. The space $\mathcal{P}(E)$ of probability measures on $E$ is equipped with the topology of the weak convergence. More precisely, we shall consider that $\mathcal{P}(E)$ is equipped with the Lévy-Prokhorov metric, which also makes it a polish space (one may refer to [2] for details regarding this topology and tightness in general).

Definition 2.1. For a random measure $\mu : \Omega \rightarrow \mathcal{P}(E)$, we define the intensity $I(\mu)$ of $\mu$ by

\[ \forall f : E \to \mathbb{R} \text{ measurable, bounded, } \langle f, I(\mu) \rangle = \mathbb{E}[\langle f, \mu \rangle], \]

that is $I(\mu) \in \mathcal{P}(E)$ is a deterministic probability measure on $E$.

The following result (mentioned e.g. in [16] p178) establishes a link between the relative compactness in law of $\mu$ and the tightness of its intensity measure $I(\mu)$.

Proposition 2.3.

For a sequence $\mu^N_{N \geq 1}$ of random measures on $E$, the two following statements are equivalent.
i) The sequence of \( \mathcal{P}(E) \)-valued random variables \((\mu^N)_N\) is tight.

ii) The sequence \((I(\mu^N))_N\) of measures on \(E\) is tight.

**Proof.** Firstly i) clearly implies ii) since

\[
\mu^N \to \mu \text{ in } \mathcal{P}(E) \text{ weakly on } \Omega \implies \left[ I(\mu^N) \to I(\mu) \text{ weakly on } E \right].
\]

Let us assume ii): we introduce a sequence \((C_m)_{m \geq 1}\) of compacts of \(E\) such that

\[
\forall m \geq 1, \sup_N I(\mu^N)(C_m) \leq 4^{-m}.
\]

For a given \(\varepsilon > 0\), let us define

\[
K_\varepsilon = \left\{ \mu \in \mathcal{P}(E), \forall m \geq 1, \mu(C_m^c) \leq \varepsilon^{-1}2^{-m} \right\}. \tag{2.8}
\]

Prokhorov’s theorem on tightness states that \(K_\varepsilon\) is a compact of \(\mathcal{P}(E)\) equipped with the Lévy-Prokhorov metric. Now, for all \(N \geq 1\), using simply Markov’s inequality,

\[
P[\mu^N \notin K_\varepsilon] \leq \sum_m P[\mu^N(C_m^c)] \leq \varepsilon \sum_m I(\mu^N)(C_m^c)2^m \leq \varepsilon.
\]

Let us extend this reasoning to the Wasserstein space \(\mathcal{P}_2(E)\) defined in (1.1). Firstly, we have the following convergence criteria.

**Proposition 2.4.** Let \(\mu^N : \Omega \to \mathcal{P}_2(E), N \geq 1\), be a family of random measures on \(E\).

The following statements are equivalent

i) \(\mu^N \to \mu \) in \(\mathcal{P}_2(E)\)

ii) \(\mu^N \to \mu \) in \(\mathcal{P}(E)\) and \(\limsup\) \(N\) \(\int_{\|x\| > R} \|x\|^2 d\mu^N(x) \to 0 \) \(R \to \infty\)

iii) \(\langle \phi, \mu^N \rangle \to \langle \phi, \mu \rangle\) for all \(\phi\) continuous such that \(\phi(x) \leq C(1 + \|x\|^2)\).

One could refer to [17], section 6 (Theorem 6.9) for a proof. This immediately results in

**Corollary 2.1** (Compact subsets of \(\mathcal{P}_2(E)\)).

A subset \(A \subset \mathcal{P}_2(E)\) is relatively compact if and only if

- The family of measures \(\mu_{\mu \in A}\) is tight

- \(\sup_{\mu \in A} \left[ \int_{\|x\| > R} \|x\|^2 d\mu(x) \right] \to 0 \) as \(R \to \infty\).

We can now state the following criteria for the relative compactness in law in \(\mathcal{P}_2(E)\).

**Proposition 2.5.** Let \(\mu^N : \Omega \to \mathcal{P}_2(E), N \geq 1\), be a family of random measures on \(E\).

The following statements are equivalent

i) \(\{I(\mu^N), N \geq 1\}\) is relatively compact in \(\mathcal{P}_2(E)\)

ii) The family of measures \((I(\mu^N))_N\) is tight and \(\sup\) \(N\) \(\int_{\|x\| > R} \|x\|^2 dI(\mu^N)(x) \to 0 \) \(R \to \infty\)

iii) The family of \(\mathcal{P}_2(E)\)-valued random variables \((\mu^N)_N\) is tight.
In this case, there exists a subsequence \((\mu^{N'})_{N'}\), a probability space \((\bar{\Omega}, \bar{\mathcal{F}})\) and random variables \(\tilde{\mu}^{N'}, \bar{\mu} : \bar{\Omega} \rightarrow \mathcal{P}_2(E)\) such that

\[
\tilde{\mu}^{N'} \sim \mu^{N'} \text{ in law}
\]

\[
W_2[\tilde{\mu}^{N'}, \bar{\mu}] \xrightarrow{N' \to \infty} 0 \text{ a.s and in } L^2(\bar{\Omega})
\]

**Proof of Proposition 2.5.** The equivalence between i) and ii) is stated in Corollary 2.1. Assuming i), we can introduce \((C_m)_{m \geq 1}\) compacts of \(E\) and \((R_m)_{m}\) with \(R_m \to \infty\) such that for all \(m \geq 1\),

\[
\sup_N I(\mu^{N})(C_m) \leq 4^{-m}, \quad \sup_N \int_{\|x\| > R_m} \|x\|^2 dI(\mu^{N})(x) \leq 4^{-m}.
\]

For a given \(\varepsilon > 0\), let us define

\[
K_{\varepsilon} = \left\{ \mu \in \mathcal{P}_2(E), \forall m \geq 1, \mu(C_m) \leq \varepsilon^{-1}2^{-m}, \int_{\|x\| > R_m} \|x\|^2 d\mu(x) \leq \varepsilon^{-1}2^{-m} \right\}
\]

which is a relatively compact subset of \(\mathcal{P}_2(E)\) by Corollary 2.1. Then, using Markov’s inequality

\[
P[\mu^N \notin K_{\varepsilon}] \leq \sum_{m \geq 1} P[\mu^N(C_m) > \varepsilon^{-1}2^{-m}] + \sum_{m \geq 1} \int_{\|x\| > R_m} \|x\|^2 d\mu^N(x) > \varepsilon^{-1}2^{-m}
\]

\[
\leq \varepsilon \sum_{m \geq 1} 2^m I(\mu^{N})(C_m) + \varepsilon \sum_{m \geq 1} \int_{\|x\| > R_m} \|x\|^2 dI(\mu^{N})(x) \leq 2\varepsilon
\]

which proves iii).

Assuming iii), let us prove the last part of the result. We introduce a subsequence \((\mu^{N'})_{N'}\) which converges in law to some \(\mu \in \mathcal{P}_2(E)\). Applying Skorokhod’s representation theorem on the polish space \(\mathcal{P}_2(E)\) we get, on \(\bar{\Omega}, \tilde{\mu}^{N'} \to \hat{\mu} \text{ a.s in } \mathcal{P}_2(E)\). To conclude regarding the convergence in \(L^2(\bar{\Omega})\), it suffices to show that \(W_2^2[\tilde{\mu}^{N'}, \hat{\mu}]\) is uniformly integrable in \(N'\).

To this purpose, one can simply write

\[
W_2^2[\tilde{\mu}^{N'}, \hat{\mu}] \leq \int \|x\|^2 d\tilde{\mu}^{N'} + \int \|x\|^2 d\hat{\mu}
\]

and for all \(R, M > 0\),

\[
\mathbb{E}\left[\int \|x\|^2 d\tilde{\mu}^{N'} \mathbf{1}_{\{\|x\| > R\}}\right] \leq \mathbb{E}\left[\int \|x\|^2 d\tilde{\mu}^{N'}\right] + M \mathbb{P}\left[\int \|x\|^2 d\tilde{\mu}^{N'} > R\right]
\]

\[
\leq \sup_N \int \|x\|^2 dI(\mu^{N}) + \frac{M}{R} \sup_N \int \|x\|^2 dI(\mu^{N}).
\]

This shows that for all \(M > 0\),

\[
\limsup_{R \to \infty} \sup_N \mathbb{E}\left[\int \|x\|^2 d\tilde{\mu}^{N'} \mathbf{1}_{\{\|x\| > R\}}\right] \leq \sup_N \int \|x\|^2 dI(\mu^{N}) \to 0 \text{ as } M \to \infty.
\]

We can now see that iii) implies i): let us introduce \(\bar{\pi}(\omega)\) an optimal coupling between \(\tilde{\mu}^{N'}(\omega)\) and \(\hat{\mu}(\omega)\), that is

\[
W_2^2[\tilde{\mu}^{N'}, \hat{\mu}](\omega) = \int_{x_1, x_2 \in E} \|x_1 - x_2\|^2 d\bar{\pi}(\omega)(x_1, x_2).
\]

Note that such a coupling exists, and can indeed be selected to be measurable, see [17], section 5, Corollary 5.22. Then \(\bar{\pi} \in \Pi[\tilde{\mu}^{N'}, \hat{\mu}]\) (for every \(\omega \in \bar{\Omega}\)) and it is clear from the definition that

\[
I(\bar{\pi}) \in \Pi[I(\tilde{\mu}^{N'}), I(\hat{\mu})] = \Pi[I(\mu^{N'}), I(\mu)].
\]
Therefore
\[
W_2^2[I(\mu^N), I(\mu)] \leq \int_{x_1, x_2 \in E} \|x_1 - x_2\|^2 dI(\bar{\pi})(x_1, x_2)
\]
\[
= \mathbb{E}\left[\int_{x_1, x_2 \in E} \|x_1 - x_2\|^2 d\bar{\pi}(x_1, x_2)\right] = \mathbb{E}\left[W_2^2[\bar{\mu}^N, \bar{\mu}]\right] \to 0 \text{ as } N' \to \infty.
\]

2.4 Proof of the weak convergence

We will now prove the result stated in Theorem 1. Consider \(\mu_0 \in \mathcal{P}(\mathbb{R}^d)\) satisfying
\[
\int |x|^{2+\delta} d\mu_0(x) < \infty \text{ for some } \delta > 0
\]
and a sequence of empirical measures \(\mu_0^N = \frac{1}{N} \sum_{i=1}^{N} \delta_{x_i}^N\) such that
\[
\mu_0^N \to \mu_0 \text{ in } \mathcal{P}_2(\mathbb{R}^d), \quad \sup_N \int |x|^{2+\delta} d\mu_0^N(x) < \infty.
\]
Let \((X_i^t, N)_{t \in [0,T]}, i \in \{1, ..., N\}\) be the solution of (1.17) with initial data \(X_0^i = x_0^i\). We shall look at these processes as random variables taking values in the (polish) space of continuous functions
\[
X_i^N : \Omega \to C = C([0,T]; \mathbb{R}^d)
\]
\[
\omega \mapsto (X_i^N(\omega))_{t \in [0,T]}.
\]
(2.9)
The associated empirical measure \(\mu^N = \frac{1}{N} \sum_{i=1}^{N} \delta_{X_i^N}\) is hence seen as a random element of \(\mathcal{P}(C)\). Its intensity measure is given by
\[
I(\mu^N)(A) = \frac{1}{N} \sum_{i=1}^{N} \mathbb{P}(X_i^N \in A), \quad A \in \mathcal{B}(C).
\]
(2.10)
Let us verify the assumptions of Proposition 2.5 to establish the compactness in law in \(\mathcal{P}_2(C)\):

1. Firstly, \(\sup_N \int_{x \in C} |x|^{2} dI(\mu^N) = \sup_N \int_{x \in \mathbb{R}^d} |x|^{2} d\mu_0^N < \infty\) and Proposition 2.2 gives
\[
\sup_N \int_{x \in C} |x_t - x_s|^{2+\delta} dI(\mu^N) = \sup_N \frac{1}{N} \sum_i \mathbb{E}[|X_i^t - X_i^s|^2] \leq \sup_N \left( \int |x|^{2+\delta} d\mu_0^N \right) |t - s|^{1+\delta/2}.
\]
Classically, using Kolmogorov’s continuity criterium, for any \(\alpha \in ]0, 1/2[,\) defining the compact subset of \(C\)
\[
K_R = \left\{ x \in \mathcal{C}, |x_0| \leq R, \sup_{t,s \in [0,T]} |x_t - x_s| \leq R |t - s|^{\alpha} \right\},
\]
we get \(\sup_N I(\mu^N)(K_R) \xrightarrow{R \to +\infty} 0\) the sequence \((I(\mu^N))\) is tight.

2. We have
\[
\int_{|x| \geq R} \|x\|^2 dI(\mu^N)(x) = \mathbb{E}\left[\int_{|x| \geq R} \|x\|^2 d\mu^N(x)\right] \leq \frac{1}{R^2} \mathbb{E}\left[\int \|x\|_{\infty}^2 d\mu^N(x)\right]
\]
and taking the mean over \(i\) in Proposition 2.1,
\[
\mathbb{E}\left[\int \|x\|_{\infty}^{2+\delta} d\mu^N(x)\right] = \frac{1}{N} \sum_{i=1}^{N} \mathbb{E}\left[\sup_{t \in [0,T]} |X_i^t|^{2+\delta}\right] \leq \int \|x\|^{2+\delta} d\mu_0^N(x)
\]
hence \(\limsup_N \int_{|x| \geq R} \|x\|_{\infty}^2 dI(\mu^N)(x) \xrightarrow{R \to +\infty} 0\).
We can therefore introduce a subsequence and some probability space \((\tilde{\Omega}, \tilde{\mathbb{P}})\) with random variables \(\tilde{\mu}^N', \tilde{\mu} : \tilde{\Omega} \to \mathcal{P}_2(\mathcal{C})\) such that
\[
\forall N', \quad \tilde{\mu}^N' \sim \mu^N' \text{ in law}
\]
\[
W_2[\tilde{\mu}^N', \tilde{\mu}] \xrightarrow{N \to \infty} 0 \text{ a.s (and in } L^2(\tilde{\Omega})\).
\]

Now, considering the law of the process \((\mu^N_t)_{t \geq 0}\) only, equation (2.7) can be translated as:
for all \(\psi \in C^2(\mathbb{R}^d)\) with \(|\nabla \psi|, |\nabla^2 \psi| \leq 1\),
\[
M^N_\psi(t) = \langle \psi, \mu^N_t \rangle - \langle \psi, \mu^N_0 \rangle - \int_0^t \langle L[\mu^N_s] \psi, \mu^N_s \rangle ds, \quad t \geq 0,
\]
where \(L[\mu] = (B[\mu] + S[\mu]) \cdot \nabla \psi + A[\mu] \psi, \quad (2.11)\)
is a continuous \(L^2\) martingale on \(\Omega\) with respect to the canonical filtration of \((\mu^N_t)_t\), whose quadratic variation is given by
\[
[M^N_\psi](t) = \int_0^t |\langle C[\mu^N_s] \cdot \nabla \psi, \mu^N_s \rangle|^2 ds + \frac{1}{N^2} \sum_i \int_0^t |\sigma^i(X^i_s \cdot \nabla \psi)(X^i_s)|^2 ds
\]
\[= \int_0^t |\langle C[\mu^N_s] \cdot \nabla \psi, \mu^N_s \rangle|^2 ds + \frac{1}{N} \int_0^t |\sigma^i \nabla \psi|^2 \mu^N_s ds.\]
Equivalently, this can be expressed as
\[
\mathbb{E}\left[ (M^N_\psi(t) - M^N_\psi(s)) h(\mu^N_{t_1}, ..., \mu^N_{t_m}) \right] = 0 \quad (2.12)
\]
\[
\mathbb{E}\left[ M^N_\psi(t) - M^N_\psi(s)^2 h(\mu^N_{t_1}, ..., \mu^N_{t_m}) \right] = \mathbb{E}\left[ \left( M^N_\psi(t) - M^N_\psi(s) \right) h(\mu^N_{t_1}, ..., \mu^N_{t_m}) \right] \quad (2.13)
\]
for all \(0 \leq t_1, ..., t_m \leq s \leq t\) and \(h : \mathcal{P}_2(\mathbb{R}^d) \to \mathbb{R}\) continuous bounded. Since \(\tilde{\mu}^N' \sim \mu^N\) in law in \(\mathcal{P}_2(\mathcal{C})\), it is clear that the processes \((\tilde{\mu}^N_t)_{t \in [0,T]}\) and \((\mu^N_t)_{t \in [0,T]}\) have the same law. It follows that (2.12) and (2.13) also hold on the probability space \((\tilde{\Omega}, \tilde{\mathbb{P}})\) for
\[
\tilde{\mu}^N_\psi(t) = \langle \psi, \tilde{\mu}^N_t \rangle - \langle \psi, \mu^N_0 \rangle - \int_0^t \langle L[\tilde{\mu}^N_s] \psi, \tilde{\mu}^N_s \rangle ds, \quad t \geq 0
\]
making it a continuous \(L^2\) martingale on \(\tilde{\Omega}\), with respect to the canonical filtration of \((\tilde{\mu}^N_t)_t\), with quadratic variation \(\tilde{[M^N_\psi]}(t) = \int_0^t |\langle C[\tilde{\mu}^N_s] \cdot \nabla \psi, \tilde{\mu}^N_s \rangle|^2 ds + \frac{1}{N^2} \int_0^t |\sigma^i \nabla \psi|^2 \tilde{\mu}^N_s ds.\)

We can now establish the following result.

**Proposition 2.6.** For all \(\psi \in C^2(\mathbb{R}^d)\) such that \(|\nabla \psi|, |\nabla^2 \psi| \leq 1\),
\[
\tilde{\mu}^N_\psi(t) = \langle \psi, \tilde{\mu}_t \rangle - \langle \psi, \mu_0 \rangle - \int_0^t \langle L[\tilde{\mu}_s] \psi, \tilde{\mu}_s \rangle ds, \quad t \geq 0
\]
is a continuous \(L^2\) martingale on \(\tilde{\Omega}\) with respect to the canonical filtration of \((\tilde{\mu}_t)_t\), whose quadratic variation is given by
\[
[M^N_\psi](t) = \int_0^t |\langle C[\tilde{\mu}_s] \cdot \nabla \psi, \tilde{\mu}_s \rangle|^2 ds =: V_\psi(t).
\]

**Proof.** Let us work on \(\tilde{\Omega}\), but drop the tildas on \(\mu, \mathbb{P}\) and the primes on \(N\) for clarity.
Given \(0 \leq s \leq t \leq T\) and \(0 \leq t_1 \leq ... \leq t_m \leq s\) and \(h\) continuous bounded, we wish to send \(N \to \infty\) in (2.12) and (2.13). It is enough to verify the following points.
1. \( M^N_\psi(t) \to M_\psi(t) \) in probability
2. \( |M^N_\psi(t)|^2 \) is uniformly integrable in \( N \)
3. \( [M^N_\psi](t) \to V_\psi(t) \) in probability
4. \( [M^N_\psi](t) \) is uniformly integrable in \( N \).

Given that \( W_2[\mu^N, \mu] \to 0 \) almost surely, using

**Lemma 2.1** (General inequality for product measures). Let \( E \) be a polish space, then

\[
\forall \mu, \mu', \nu, \nu' \in \mathcal{P}_2(E), \quad W_2^2[\mu \otimes \mu', \nu \otimes \nu'] \leq W_2^2[\mu, \nu] + W_2^2[\mu', \nu'].
\]

we also derive that \( W_2((\mu^N)^{\otimes 2}, (\mu^N)^{\otimes 2}), W_2((\mu^N)^{\otimes 3}, (\mu^N)^{\otimes 3}) \to 0 \). Recalling (2.11), let us review the different terms involved in \( M^N_\psi(t) \).

- Since \( |\psi(x)| \leq 1 + |x|, (\psi, \mu^N_t) \to (\psi, \mu) \) a.s and \( |(\psi, \mu^N_t)| \leq 1 + \|x\|_\infty d\mu^N(x) \).
- The term \( \int_0^t \int_{\mathbb{R}^d} b(x,y) \cdot \nabla \psi(x) d(\mu^N_s \otimes \mu^N_s)(x,y) ds \) can be written as

\[
\int_0^t \int_{\mathbb{R}^d} b(x,y) \cdot \nabla \psi(x) d(\mu^N_s \otimes \mu^N_s)(x,y) ds = \int_0^t \int_{\mathbb{R}^d} b(x_s, y_s) \cdot \nabla \psi(x_s) ds d(\mu^N_s \otimes \mu^N_s)(x,y)
\]

which converges almost surely to the expected term since the functional is indeed sub-quadratic (\( |b(x,y)| \lesssim |x| + |y| \) and \( |\nabla \psi| \lesssim 1 \)). The term involving \( S[\mu^N] \) is treated in the same way.

- Recalling the form (1.20), the term \( \int_0^t \langle A[\mu^N_s] \psi, \mu^N_s \rangle ds \) can be written similarly as

\[
\sum_{i,j} \int_0^t \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \left[ \sum_k \sigma_{i,k}(x) \sigma_{j,k}(x) + c_i(x,y) c_j(x,z) \right] \partial^2_{ij} \psi(x) d(\mu^N_s \otimes \mu^N_s \otimes \mu^N_s)(x,y,z) ds.
\]

again, this converges almost surely since

\[
|\sigma_{i,k}(x) \sigma_{j,k}(x)| \lesssim 1 + |x|^2, \quad |c_i(x,y) c_j(x,z)| \lesssim 1 + |x|^2 + |y|^2 + |z|^2, \quad |\nabla^2 \psi| \lesssim 1.
\]

Point 1. is hence proven. Let us skip Point 2. for now and consider \( [M^N_\psi](t) \). Using the same arguments as before, \( \left| \langle C[\mu^N_s] \cdot \nabla \psi, \mu^N_s \rangle \right|^2 \to \left| \langle C[\mu_s] \cdot \nabla \psi, \mu_s \rangle \right|^2 \) almost surely for fixed \( s \in [0, t] \).

The bound

\[
\left| \langle C[\mu^N_s] \cdot \nabla \psi, \mu^N_s \rangle \right|^2 \lesssim 1 + \|x\|_\infty^2 d\mu^N(x), \quad \text{with} \quad \sup_N \mathbb{E} \left[ \int \|x\|_\infty^{2+\delta} d\mu^N(x) \right] < \infty
\]

guarantees the uniform integrability in \((t, \omega)\), so that

\[
\int_0^t \left| \langle C[\mu^N_s] \cdot \nabla \psi, \mu^N_s \rangle \right|^2 \to \int_0^t \left| \langle C[\mu_s] \cdot \nabla \psi, \mu_s \rangle \right|^2 = V_\psi(t) \text{ in } L^1(\tilde{\Omega}),
\]

in particular in probability. Additionally, \( \left| \langle |\sigma^* \nabla \psi|^2, \mu^N_s \rangle \right| \lesssim 1 + \|x\|_\infty^2 d\mu^N(x) \) which is bounded in \( L^1(\tilde{\Omega}) \) uniformly in \( N \), so that

\[
\frac{1}{N} \int_0^t \left| \langle |\sigma^* \nabla \psi|^2, \mu^N_s \rangle \right| \to 0 \text{ in } L^1(\tilde{\Omega})
\]
in particular in probability, which proves point 3.
We have in fact just seen that \( \left| M_N \right|(t)^{1+\delta/2} \leq 1 + \int \|x\|^{2+\delta} d\mu_N(x) \) which is bounded in \( L^1(\Omega) \) uniformly in \( N \), hence giving point 4. Finally, Burkholder-Davis-Gundy’s inequality gives
\[
\mathbb{E}\left| M_N(t) \right|^{2+\delta} \leq \mathbb{E}\left[ \left| M_N(t) \right|^{1+\delta/2} \right]^2
\]
and we derive point 2 from point 4.
Let us conclude by giving a proof of Lemma 2.1. Let \( \pi \in \Pi(\mu, \nu) \) and \( \pi' \in \Pi(\mu', \nu') \). With a slight abuse of language, defining \( \pi \otimes \pi' \in \mathcal{P}(E^2 \times E^2) \) by
\[
\int_{(x,x')} \int_{(y,y')} h(x,x',y,y') d(\pi \otimes \pi')(\langle x,x' \rangle; \langle y,y' \rangle) = \int_{(x',y')} \int_{(x,y)} h(x,x',y,y') d\pi(x,y) d\pi'(x',y')
\]
we have \( \pi \otimes \pi' \in \Pi(\mu \otimes \mu', \nu \otimes \nu') \). Indeed, for \( h \equiv h(x,x') \),
\[
\int_{(x,x')} \int_{(y,y')} h(x,x') d(\pi \otimes \pi')(\langle x,x' \rangle; \langle y,y' \rangle) = \int_{(x',y')} \int_{(x,y)} h(x,x') d\pi(x,y) d\pi'(x',y') = \int_{(x,x')} h(x,x') d(\mu \otimes \mu')(x,x')
\]
and similarly for \( h \equiv h(y,y') \). Therefore, it follows that
\[
W_2^2[\mu \otimes \mu', \nu \otimes \nu'] \leq \int_{(x,x')} \int_{(y,y')} \| (x,x') - (y,y') \|^2 d(\pi \otimes \pi')(\langle x,x' \rangle; \langle y,y' \rangle)
\]
\[
= \int_{(x',y')} \int_{(x,y)} \| x - y \|^2 + \| x' - y' \|^2 d\pi(x,y) d\pi'(x',y')
\]
\[
= \int_{(x,x')} \| x - y \|^2 d\pi(x,y) + \int_{(x',y')} \| x' - y' \|^2 d\pi'(x',y').
\]
Taking the infimum over all \( \pi \in \Pi(\mu, \nu) \) and \( \pi' \in \Pi(\mu', \nu') \) gives the required inequality.

From \( (\mu_t)_{t \geq 0} \) satisfying this martingale problem stated in Proposition 2.6, we classically construct a weak solution using a martingale representation theorem in some Hilbert space.

We start by noting that \( \mathcal{P}_2(\mathbb{R}^d) \) is continuously embedded in the Sobolev space \( H^{-\gamma} = (H^\gamma)' \) (where \( H^\gamma = W^{\gamma,2}(\mathbb{R}^d) \)) as soon as \( \gamma > 1 + d/2 \). Indeed, for \( \psi \in H^\gamma \),
\[
\left| \langle \psi, \mu \rangle - \langle \psi, \nu \rangle \right| \leq \| \nabla \psi \|_\infty W_2[\mu, \nu] \leq C \| \psi \|_{H^\gamma} W_2[\mu, \nu]
\]
where we have used the continuous Sobolev embedding \( H^\gamma \subset C^1_0 \) for \( \gamma > 1 + d/2 \). We may consider the \( H^{-\gamma-2} \)-valued process
\[
\tilde{M}(t) = \tilde{\mu}_t - \mu_0 - \int_0^t L[\tilde{\mu}_s] \tilde{\psi}_s ds, \quad t \in [0, T]
\]
which satisfies, for all \( \psi \in H^{\gamma+2} \) (a Sobolev embedding gives \( |\nabla \psi|, |\nabla^2 \psi| \leq 1 \)),
\[
\langle \tilde{M}(t), \psi \rangle = \tilde{M}_\psi(t), \quad t \in [0, T],
\]
which is a continuous $L^2$ martingale with respect to the filtration $\tilde{F}_t = \sigma\left(\tilde{\mu}_s \in \mathcal{P}_2(\mathbb{R}^d), \ s \in [0, t]\right)$, $t \in [0, T]$, with quadratic variation $V_\psi(t)$. Using a polarisation formula, we deduce more precisely that for $\psi_1, \psi_2 \in H^{\gamma+2}$,

$$\langle \tilde{M}(t), \psi_1 \rangle \langle \tilde{M}(t), \psi_2 \rangle - \langle V(t) \psi_1, \psi_2 \rangle, \ t \in [0, T]$$

is a continuous $(\tilde{F}_t)$-martingale, where

$$\langle V(t) \psi_1, \psi_2 \rangle = \int_0^t (C[\tilde{\mu}_s] \cdot \nabla \psi_1, \tilde{\mu}_s) (C[\tilde{\mu}_s] \cdot \nabla \psi_2, \tilde{\mu}_s) ds.$$

The martingale representation theorem from [11] p.222 (Theorem 9.2) then holds, giving another probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$ with a filtration $(\tilde{F}_t)_{t \in [0, T]}$ and a $(\tilde{F}_t \times \tilde{F}_t)$-brownian motion $(W_t)_{t \in [0, T]}$ on $(\tilde{\Omega} \times \tilde{\Omega}, \tilde{\mathcal{F}} \otimes \tilde{\mathcal{F}})$ such that

$$\forall (\tilde{\omega}, \tilde{\omega}) \in \tilde{M}(t)(\tilde{\omega}, \tilde{\omega}) = \tilde{M}(t)(\tilde{\omega}) = -\int_0^t \nabla \cdot (C[\tilde{\mu}_s(\tilde{\omega})] \tilde{\mu}_s(\tilde{\omega})) dW_s(\tilde{\omega}, \tilde{\omega}).$$

It follows that $(\tilde{\omega}, \tilde{\omega}) \mapsto (\tilde{\mu}_t(\tilde{\omega}))_{t \in [0, T]}$ is a solution of (1.11) on $\tilde{\Omega} \times \tilde{\Omega}$ according to Definition 1.2 (whose law is of course the same as that of $\tilde{\omega} \mapsto (\tilde{\mu}_t(\tilde{\omega}))_{t \in [0, T]}$).

### 3 Strong mean-field convergence

In this section, for simplicity, we restrict ourselves to the setting of a common noise, according to Assumption 3.

In this case, the limiting SPDE (1.11) becomes a stochastic conservation equation (given by (1.15)) and solutions $\mu_t$ are naturally expected to be obtained as the push-forward measures of $\mu_0$ through the flow of the associated (non-linear) stochastic characteristics.

#### 3.1 Stochastic characteristics

Let us suppose that Assumptions 1 and 2 hold.

**Definition 3.1.**

Given some random $\mu \in \mathcal{P}_2(\mathbb{C})$ such that $E \int \|x\|_\infty^2 d\mu(x) < \infty$, the characteristics $X^\mu$ are defined as the solution of

$$
\begin{cases}
  dX^\mu_t(x) = \left( B[\mu] + S[\mu_t] \right) (X^\mu_t(x)) dt + C[\mu_t](X^\mu_t(x)) dB_t, \ t \in [0, T], \\
  X^\mu_0(x) = x \in \mathbb{R}^d.
\end{cases}
$$

(3.1)

A random measure $\mu : \Omega \rightarrow \mathcal{P}_2(\mathbb{C})$ is said to be "of the transport form" if it satisfies the fixed-point like identity

$$\mu = (X^\mu)^* \mu_0 \ a.s$$

(3.2)

where $X^\mu = (X^\mu_t(x))_{t \in [0, T], x \in \mathbb{R}^d}$ is the flow of characteristics associated to (3.1) and the measure $(X^\mu)^* \mu_0 \in \mathcal{P}(\mathbb{C})$ is defined by: for all $m \geq 1, \ t_1, \ldots, t_m \in [0, T], \ \psi \in C^1((\mathbb{R}^d)^m, \mathbb{R})$,

$$
\int_{\mathbb{C}} \psi(x_{t_1}, \ldots, x_{t_m}) d((X^\mu)^* \mu_0)(x) = \int_{\mathbb{R}^d} \psi(X^\mu_{t_1}(x), \ldots, X^\mu_{t_m}(x)) d\mu_0(x).
$$

**Remark 3.1.** It is to be noted that, under Assumptions 1 and 2, the flow $x \mapsto X^\mu_0(x) \in \mathcal{C}$ is almost-surely continuous, so that the push-forward measure $(X^\mu)^* \mu_0$ is indeed well defined. This can easily be seen in the case where the kernels $b, c, s_1$ are globally Lipschitz-continuous, since we can derive some Kolmogorov estimate of the form

$$E\left[ \sup_{t \in [0, T]} |X^\mu_t(x) - X^\mu_t(x')|^p \right] \lesssim |x - x'|^p.$$

The result follows in the locally Lipschitz-continuous case using a classic stopping-time method (found e.g. in [13]).
Measures of the transport form are, by design, solutions of the conservation equation (1.15)

**Proposition 3.1.** Let \( \mu_0 \in \mathcal{P}(C) \) and \( \mu = (X^\mu)^* \mu_0 \) be of the transport form. Then \( \mu = (\mu_t)_{t \in [0,T]} \) satisfies the SPDE (1.15) in the sense of Definition 1.2.

**Proof.** Firstly, using the same reasoning as in the proof of Proposition 2.1, one can easily show

\[
\mathbb{E} \int_C |x|^2 d\mu(x) = \mathbb{E} \int_{\mathbb{R}^d} \sup_{t \in [0,T]} |X^\mu_t(x)|^2 d\mu_0(x) \lesssim \int_{\mathbb{R}^d} |x|^2 d\mu_0(x), \tag{3.3}
\]

so that the characteristics (3.1) are globally well-defined. For any \( \psi \in C^2_c(\mathbb{R}^d) \), since \( \mu \in \mathcal{P}(C) \), the process \((\langle \psi, \mu_t \rangle)_{t \in [0,T]}\) is automatically (adapted and) almost surely continuous. Itô’s formula then results in

\[
\psi(X^\mu_t(x)) = \psi(x) + \int_0^t \nabla \psi(X^\mu_s(x)) \cdot (B[\mu_s] + S[\mu_s] + A[\mu_s])(X^\mu_s(x)) ds + \int_0^t \nabla \psi(X^\mu_s(x)) \cdot C[\mu_s](X^\mu_s(x)) d\beta_s.
\]

Note that, using the sublinearity Assumption 1 and the estimate (3.3), the stochastic integral involved here easily defines a square-integrable martingale. Integrating with respect to \( d\mu_0(x) \) using a stochastic Fubini theorem gives exactly (1.19), so that Definition 1.2 is satisfied. \( \square \)

We now formulate an estimate which locally compares two solutions of the transport form.

**Proposition 3.2** (\( \mathcal{P}_p \)-comparison estimate for compactly-supported initial data).

Let \( \mu_0, \tilde{\mu}_0 \in \mathcal{P}(\mathbb{R}^d) \) be supported in some compact set \( K \subset \mathbb{R}^d \), and let \( \mu, \tilde{\mu} : \Omega \rightarrow \mathcal{P}_2(C) \) be of the transport form. For all \( p > 1 \), \( R > 0 \), defining the stopping time

\[
\tau_R = \inf \left\{ t \geq 0, \sup_{x \in K} (|X^\mu_t(x)| + |X^\tilde{\mu}_t(x)|) \geq R \right\} \wedge T
\]

there exists some constant \( C_{p,R,T} > 0 \) such that

\[
\mathbb{E} \left[ \sup_{t \in \llbracket 0, \tau_R \rrbracket} W^p_p[\mu_t, \tilde{\mu}_t] \right] \leq C_{p,R,T} W^p_p[\mu_0, \tilde{\mu}_0]. \tag{3.4}
\]

**Remark 3.2.** Given some sequence \( (x_k)_{k \geq 1} \) dense in \( K \), the continuity of \( x \mapsto X^\mu_0(x) \in \mathcal{C} \) gives

\[
\{ \tau_R \geq t \} = \left\{ \sup_{x \in K} \left( |X^\mu_{t'}(x)| + |X^\tilde{\mu}_{t'}(x)| \right) \leq R \right\} \bigcap_{k \geq 1} \{ \tau_R(x_k) \geq t \}
\]

where \( \tau_R(x) = \inf \left\{ t \geq 0, |X^\mu_t(x)| + |X^\tilde{\mu}_t(x)| \geq R \right\} \wedge T \) is a stopping time, so that \( \tau_R \) is indeed a stopping time.

**Proof.** For the sake of making calculations clearer, we only treat the case \( p = 2 \). Let us forget about \( S[\mu] \) since it plays the same role as \( B[\mu] \). Let us introduce a local Lipschitz constant \( c_R > 0 \) so that for all \( |x|, |y|, |x'|, |y'| \leq R, \)

\[
\begin{align*}
|b(x, y) - b(x', y')| &\leq c_R \left( |x - x'| + |y, y'| \right) \\
|c(x, y) - c(x', y')| &\leq c_R \left( |x - x'| + |y, y'| \right) \\
|c(x, y)| &\leq c_R.
\end{align*}
\]
This easily results in the following for all $|x|, |x'| \leq R, \nu, \nu'$ with support in $B(0, R)$,

\[
\begin{align*}
|B[\nu](x) - B[\nu'](x')| &\leq c_R \left( |x - x'| + W_1[\nu, \nu'] \right) \leq c_R \left( |x - x'| + W_2[\nu, \nu'] \right) \\
|C[\nu](x) - C[\nu'](x')| &\leq c_R \left( |x - x'| + W_1[\nu, \nu'] \right) \leq c_R \left( |x - x'| + W_2[\nu, \nu'] \right) \\
|C[\nu](x)| &\leq c_R.
\end{align*}
\]

(3.5)

We may introduce a measurable optimal transport map $T : K \to K$ so that

\[
W^2_2[\mu_0, \tilde{\mu}_0] = \int_K |x - T(x)|^2 d\mu_0(x).
\]

Since $\mu, \tilde{\mu}$ are of the transport form, denoting $X = X^\mu$ and $\tilde{X} = X^{\tilde{\mu}}$, it follows that

\[
W^2_2[\mu_t, \tilde{\mu}_t] \leq J_t := \int_K \left| X_t(x) - \tilde{X}_t(T(x)) \right|^2 d\mu_0(x).
\]

(3.6)

We now apply Itô’s formula to $\eta_t(x) = X_t(x) - \tilde{X}_t(T(x))$ to get

\[
d|\eta_t(x)|^2 = \left( 2\eta_t(x) \cdot \left[ B[\mu_t](X_t(x)) - B[\tilde{\mu}_t](\tilde{X}_t(T(x))) + C[\mu_t](X_t(x)) - C[\tilde{\mu}_t](\tilde{X}_t(T(x))) \right]^2 \right) dt + 2\eta_t(x) \cdot \left( C[\mu_t](X_t(x)) - C[\tilde{\mu}_t](\tilde{X}_t(T(x))) \right) d\beta_t.
\]

Applying (3.5), we deduce, for some $C_R > 0$,

\[
d|\eta_{t\wedge R}(x)|^2 \leq C_R \left( |\eta_{t\wedge R}(x)|^2 + W^2_2[\mu_{t\wedge R}, \tilde{\mu}_{t\wedge R}] \right) dt + dM_{t\wedge R}(x)
\]

\[
\leq C_R \left( |\eta_{t\wedge R}(x)|^2 + J_{t\wedge R} \right) dt + dM_{t\wedge R}(x)
\]

(3.7)

with $M_t(x) = \int_0^t \left( 2\eta_s(x) \cdot \left( C[\mu_s](X_s(x)) - C[\tilde{\mu}_s](\tilde{X}_s(T(x))) \right) \right) d\mu_0(x)$. We may integrate this expression with respect do $d\mu_0(x)$ using a stochastic Fubini theorem to get

\[
dJ_{t\wedge R} \leq C_R J_{t\wedge R} dt + dM_{t\wedge R}
\]

(3.8)

with $M_t = \int_0^t \left( \int_K 2\eta_s(x) \cdot \left( C[\mu_s](X_s(x)) - C[\tilde{\mu}_s](\tilde{X}_s(T(x))) \right) d\mu_0(x) \right) dt$. Taking the expectation in (3.8) and applying Grönwall’s lemma leads to

\[
\forall t \in [0, T], \quad \mathbb{E}[J_{t\wedge R}] \leq C_{R,T} W^2_2[\mu_0, \tilde{\mu}_0].
\]

Coming back to (3.8) one may now write, using Burkholder-Davis-Gundy’s inequality

\[
\mathbb{E} \left[ \sup_{[0,T]} J_{t\wedge R} \right] \leq C_R \mathbb{E} \int_0^T |J_{t\wedge R}| dt + \mathbb{E} \left[ \sup_{[0,T]} M_{t\wedge R} \right] \leq C_{R,T} W^2_2[\mu_0, \tilde{\mu}_0] + C \mathbb{E} \left( |M|^{1/2}_{T\wedge R} \right).
\]

With

\[
[M]_{T\wedge R} = 4 \int_0^T \left( \int_K \eta_{t\wedge R}(x) \cdot \left( C[\mu_{t\wedge R}](X_{t\wedge R}(x)) - C[\tilde{\mu}_{t\wedge R}](\tilde{X}_{t\wedge R}(T(x))) \right) d\mu_0(x) \right)^2 dt
\]

\[
\leq 4C_R \int_0^T \left( \int_K \left| \eta_{t\wedge R}(x) \right| \left( \eta_{t\wedge R}(x) + W_2[\mu_{t\wedge R}, \tilde{\mu}_{t\wedge R}] \right) \right)^2 dt
\]

\[
\leq C_R \int_0^T (J_{t\wedge R})^2 dt \leq C_R \left( \sup_{[0,T]} J_{t\wedge R} \right) \int_0^T J_{t\wedge R} dt.
\]

20
Hölder’s inequality classically gives
\[ E\left[ \sup_{t \in [0,T]} J_{t \wedge \tau_R} \right] \leq C_{R,T} W_2^2 [\mu_0, \tilde{\mu}_0] + C_{R,T} E\left[ \sup_{t \in [0,T]} J_{t \wedge \tau_R} \right]^{1/2} W_2 [\mu_0, \tilde{\mu}_0] \]
from which we easily derive
\[ E\left[ \sup_{t \in [0,T]} W_2^2 [\mu_t, \tilde{\mu}_t] \right] \leq E\left[ \sup_{t \in [0,T]} J_{t \wedge \tau_R} \right] \leq C_{R,T} W_2^2 [\mu_0, \tilde{\mu}_0]. \tag{3.9} \]

**Remark 3.3.** Seeing \( \mu = (X)^* \mu_0 \) and \( \tilde{\mu} = (\tilde{X})^* \tilde{\mu}_0 \) as random elements of \( \mathcal{P}_p(\mathcal{C}) \), we can in fact be a little more precise. With \( \mathcal{T} : K \to K \) an optimal transport between \( \mu_0 \) and \( \tilde{\mu}_0 \), we have
\[ W_p^p [\mu_t, \tilde{\mu}_t] \leq J_{\mathcal{T}}^* := \left( \sup_{K} \int_{\mathcal{T} \in [0,T]} \left| X_t(x) - \tilde{X}_t(\mathcal{T}(x)) \right|^p \, d\mu_0(x) \right) \tag{3.10} \]
and one could easily adapt the proof (apply BDG’s inequality in (3.7) before integrating) to get the estimate
\[ E[J_{\mathcal{T}}^*] \leq C_{p,R,T} W_p^p [\mu_0, \tilde{\mu}_0]. \tag{3.11} \]

The result from Proposition 3.2 makes it clear that, given a compactly-supported measure \( \mu_0 \), one should naturally require some estimates regarding the growth of the support of \( \mu_t \), that is, estimates on \( \sup_{x \in K} |X_t^\mu(x)| \). In [6] and [14] for instance, where the diffusion coefficient \( c(x, y) \) is linear, precise almost-sure estimates for the support of \( \mu_t \) are achieved using some stochastic Grönwall inequality.

The assumptions from Theorem 2 provide another setting (where, in particular, the diffusion coefficient is bounded) in which we are able to obtain a bound on the moments
\[ E \left( \sup_{x \in K} \sup_{t \in [0,T]} |X_t^\mu(x)|^p \right), \quad p \geq 1. \]

### 3.2 Assumptions on the coefficients

From this point on, we suppose that Assumptions 4 and 5 are satisfied.

Note that, as mentioned in the introduction, these assumptions allow us to consider stochastic Cucker-Smale models with "truncated velocities" in the interaction perturbation, given by (1.7). Indeed, this corresponds to coefficients of the form
\[ b((x, v); (y, w)) = \begin{pmatrix} \psi(x - y)(w - v) \\ \phi(x - y)(w - v) \end{pmatrix}, \quad c((x, v); (y, w)) = \begin{pmatrix} 0 \\ \phi(x - y) \mathcal{R}(w - v) \end{pmatrix}. \tag{3.12} \]

Provided that the weight functions \( \psi, \phi \) and the truncation function \( \mathcal{R} \) satisfy, for some \( \theta \in (0, 1) \),
\[ |\psi(x)|, \quad |\phi(x)|, \quad |\mathcal{R}(v)| \lesssim 1, \]
\[ |\psi(x) - \psi(y)| \lesssim (1 + |x|^{\theta} + |y|^{\theta})|x - y|, \]
\[ |\phi(x) - \phi(y)| \lesssim (1 + |x|^{\theta} + |y|^{\theta})|x - y|, \]
\[ |\mathcal{R}(v) - \mathcal{R}(w)| \lesssim (1 + |v|^{\theta} + |w|^{\theta})|v - w|, \]
\[ |\nabla \mathcal{R}(v) - \nabla \mathcal{R}(w)| \lesssim (1 + |v|^{2\theta} + |w|^{2\theta})|v - w|, \]
\[ |\psi(x)|, \quad |\phi(x)|, \quad |\mathcal{R}(v)| \lesssim 1, \]
\[ |\psi(x) - \psi(y)| \lesssim (1 + |x|^{\theta} + |y|^{\theta})|x - y|, \]
\[ |\phi(x) - \phi(y)| \lesssim (1 + |x|^{\theta} + |y|^{\theta})|x - y|, \]
\[ |\mathcal{R}(v) - \mathcal{R}(w)| \lesssim (1 + |v|^{\theta} + |w|^{\theta})|v - w|, \]
\[ |\nabla \mathcal{R}(v) - \nabla \mathcal{R}(w)| \lesssim (1 + |v|^{2\theta} + |w|^{2\theta})|v - w|, \]
one can check that all the required assumptions are satisfied, with, denoting $z_i = (x_i, v_i)$,
\[
s_1(z_1, z_2, z_3) = \begin{pmatrix}
-\phi(x_1 - x_2)\phi(x_1 - x_3)\n+\phi(x_1 - x_2)\phi(x_2 - x_3)
\end{pmatrix} \begin{pmatrix}
\phi(x_1 - x_2)\phi(x_1 - x_3)\n+\phi(x_1 - x_2)\phi(x_2 - x_3)
\end{pmatrix}.
\]

From Assumptions 4 and 5, we easily derive
\[
|B[\mu](x)| \lesssim 1 + |x| + \int |y|d\mu(y) \quad (3.13)
\]
\[
|B[\mu](x) - B[\mu](x')| \lesssim (1 + |x|^2 + |x'|^2 + \int |y|^2d\mu(y))|x - x'| \quad (3.14)
\]
and similar estimates for $S[\mu]$, as well as
\[
|C[\mu](x)| \lesssim 1 \quad (3.15)
\]
\[
|C[\mu](x) - C[\mu](x')| \lesssim (1 + |x|^\theta + |x'|^\theta + \int |y|^\theta d\mu(y))|x - x'|. \quad (3.16)
\]

### 3.3 Estimates on the stochastic characteristics

In this context, let us start by establishing some exponential moments for the stochastic characteristics.

**Lemma 3.1 (Exponential moments).**

Let $\mu_0 \in P_2(\mathbb{R}^d)$ and $\mu : \Omega \to P_2(C)$ be of the transport form.

Then, for all $T > 0$, $\alpha_0 \in (0, 1]$, there exists $\alpha_T > 0$ and $C_T > 0$ such that for $t \in [0, T]$, $x \in \mathbb{R}^d$,
\[
\mathbb{E}\left[\exp\left(\alpha_T \left|X^\mu_t(x)\right|^2 + \int |y|^2d\mu_t(y)\right)\right] \leq C_T \exp\left(\alpha_0 \left(|x|^2 + \int |y|^2d\mu_0(y)\right)\right). \quad (3.17)
\]

**Proof.** This method is inspired from the one developed in [3], Lemma 3.5. Again, let us forget $S[\mu]$ since it satisfies the same estimates as $B[\mu]$. Itô’s formula gives
\[
d[|X^\mu_t(x)|^2] = \left(2X^\mu_t(x) \cdot B[\mu_t](X^\mu_t(x)) + |C[\mu]_t(X^\mu_t(x))|^2\right)dt + 2X^\mu_t(x) \cdot C[\mu_t](X^\mu_t(x))d\beta_t.
\]

Integrating with respect to $d\mu_t(x)$ leads to
\[
d\left[\int |y|^2d\mu_t(y)\right] = \left[\int \left(2y \cdot B[\mu_t](y) + |C[\mu_t](y)|^2\right)d\mu_t(y)\right]dt + \left[\int \left(2y \cdot C[\mu_t](y)\right)d\mu_t(y)\right]d\beta_t.
\]

Hence, letting $Y_t = |X^\mu_t(x)|^2 + \int |y|^2d\mu_t$ and summing these two identities, we get
\[
dY_t = a_t dt + \sigma_t d\beta_t
\]
with, using (3.13) and (3.15), $|a_t|, |\sigma_t|^2 \lesssim (1 + Y_t)$. Let $\alpha(t)$ be a deterministic, positive smooth function to be fixed later on. Letting $Z_t = \exp\left(\alpha(t)Y_t\right)$, it follows that, for some $C > 0$,
\[
dZ_t = Z_t\left(\alpha'(t)Y_t + \alpha(t)a_t + \frac{\alpha(t)^2}{2}\sigma_t^2\right)dt + Z_t\alpha(t)\sigma_t d\beta_t
\]
\[
\leq Z_t\left(\alpha'(t)Y_t + C(1 + Y_t)(\alpha(t) + \alpha(t)^2)\right)dt + Z_t\alpha(t)\sigma_t d\beta_t
\]
\[
= Z_tY_t\left(\alpha'(t) + Ca(t) + Ca^2(t)\right)dt + CZ_t\left(\alpha(t) + \alpha(t)^2\right)dt + Z_t\alpha(t)\sigma_t d\beta_t.
\]

22
Choosing \(\alpha(t)\) so that \(\alpha' + C\alpha + C\alpha^2 \leq 0\), that is for instance \(\alpha(t) = \alpha_0 e^{-2Ct}\), we are led to
\[
dZ_t \leq C\alpha_0 Z_t dt + Z_t \alpha(t) \sigma_t d\beta_t,
\]
(3.18)
hence taking the expectation (again, one may use a stopping time to be more rigorous) and applying Grönwall’s lemma gives
\[
\mathbb{E}\left[Z_t\right] \leq \exp(C\alpha_0 T) \exp\left(\alpha_0 \left(|x|^2 + \int |y|^2 d\mu_0(y)\right)\right).
\]
This is the expected result with \(\alpha_T = \inf_{t \in [0,T]} \alpha(t) = \alpha_0 e^{-2CT}\) and \(C_T = \exp(C\alpha_0 T)\).

We can now establish some bounds regarding the support of \(\mu_t\).

**Proposition 3.3** (Kolmogorov continuity estimates for the stochastic characteristics).

Let \(\mu_0 \in \mathcal{P}(\mathbb{R}^d)\) be supported in some compact set \(K \subset \mathbb{R}^d\), and \(\mu : \Omega \to \mathcal{P}_2(\mathcal{C})\) be of the transport form. For all \(T > 0\), \(p > 1\), there exists a constant \(C_{K,T,p}\) such that
\[
\forall x, x' \in K, \quad \mathbb{E} \left[ \sup_{t \in [0,T]} |X^\mu_t(x) - X^\mu_t(x')|^p \right] \leq C_{K,T,p} |x - x'|^p.
\]

Using Kolmogorov’s continuity theorem, one can then bound all the moments of the \(\alpha\)-Hölder constant
\[
N_\alpha(X^\mu) = \sup_{x, x' \in K} \sup_{t \in [0,T]} \frac{|X^\mu_t(x) - X^\mu_t(x')|}{|x - x'|^\alpha}
\]
for all \(\alpha \in (0, 1)\). The set \(K\) being compact, an immediate consequence is the following.

**Corollary 3.1.** Let \(\mu_0 \in \mathcal{P}(\mathbb{R}^d)\) be supported in some compact set \(K \subset \mathbb{R}^d\), and \(\mu : \Omega \to \mathcal{P}_2(\mathcal{C})\) be of the transport form. For all \(T > 0\), \(p > 1\), there exists a constant \(C_{K,T,p}\) such that
\[
\mathbb{E} \left[ \sup_{x \in K \setminus [0,T]} \sup_{x' \in K} |X^\mu_t(x)|^p \right] \leq C_{K,T,p}.
\]

**Proof of Proposition 3.3.** Let us once again forget \(S[\mu]\). Letting \(\eta_t = X^\mu_t(x) - X^\mu_t(x')\), Itô’s formula gives
\[
d|\eta_t|^2p = 2p|\eta_t|^{2p-2} \eta_t \cdot d\eta_t + 2p(p-1) \sum_{i,j=1}^d |\eta_t|^{2p-4} \eta_t^i \eta_t^j d[\eta^i, \eta^j]_t + p \sum_{i=1}^d |\eta_t|^{2p-2} d[\eta^i]_t
\]
with
\[
d\eta_t = (B[\mu_t](X^\mu_t(x)) - B[\mu_t](X^\mu_t(x'))) dt + (C[\mu_t](X^\mu_t(x)) - C[\mu_t](X^\mu_t(x'))) d\beta_t
\]
\[
\eta_t^i \eta_t^j = (C^i[\mu_t](X^\mu_t(x)) - C^i[\mu_t](X^\mu_t(x'))) (C^j[\mu_t](X^\mu_t(x)) - C^j[\mu_t](X^\mu_t(x'))) dt.
\]
Using the Lipschitz estimates from (3.14) and (3.16), we derive that, for some \(C_* \geq 1\),
\[
|\eta_t|^2p \leq \lambda_t |\eta_t|^{2p} dt + dM_t,
\]
with
\[
\lambda_t \equiv \lambda_t(x, x') := C_* \left(1 + |X^\mu_t(x)|^2 \theta + |X^\mu_t(x')|^2 \theta + \int |y|^2 \theta d\mu_t\right),
\]
(3.20)
\[
M_t = \int_0^t 2p|\eta_s|^{2p-2} \eta_s \cdot (C[\mu_s](X^\mu_s(x)) - C[\mu_s](X^\mu_s(x'))) d\beta_s.
\]
(3.21)
Let us define
\[ \Lambda_t \equiv \Lambda_t(x, x') := \gamma \int_0^t \lambda_s(x, x') ds, \] (3.22)
where the constant \( \gamma \geq 1 \) is to be fixed later on. One can now write
\[ \mathbb{E} \left[ \sup_{[0, T]} |\eta|^p \right] \leq \mathbb{E} \left[ \exp \left( \frac{\Lambda_T}{2} \right) \sup_{[0, T]} \left( \exp \left( -\frac{\Lambda_t}{2} \right) |\eta|^p \right) \right] \]
\[ \leq \mathbb{E} \left[ \exp(\Lambda_T) \right]^{1/2} \mathbb{E} \left[ \sup_{[0, T]} (\exp (-\Lambda_t) |\eta|^{2p}) \right]^{1/2}. \] (3.23)

Let us fix \( \alpha_0 = 1 \) and introduce \( \alpha_T > 0 \) such that the estimate from Proposition 3.1 holds. Then,
\[ \mathbb{E} \left[ \exp(\Lambda_T) \right] \leq \int_0^T \mathbb{E} \left[ \exp(\gamma \Lambda_t) \right] dt = \int_0^T \mathbb{E} \left[ \exp \left( \gamma C_\ast (1 + |X^\mu_t(x)|^2 + |X^\mu_t(x')|^2) + \int |y|^{2\theta} d\mu_t \right) \right] dt \]
\[ \leq C_\# \int_0^T \int_0^T \mathbb{E} \left[ \exp \left( \frac{\alpha_T}{2} \left( |X^\mu_t(x)|^2 + |X^\mu_t(x')|^2 + \int |y|^{2\theta} d\mu_t(y) \right) \right] dt, \] (3.24)
where the constant \( C_\# = C_\#(T, \gamma) > 0 \) is chosen large enough so that (recall that \( \theta \in [0, 1) \))
\[ \forall u \in \mathbb{R}^+, \exp \left( \gamma C_\ast (1 + u^{2\theta}) \right) \leq C_\# \exp \left( \frac{\alpha_T u^2}{2} \right). \]

We may now use Hölder’s inequality in (3.24) and apply the estimate from Proposition 3.1 to conclude
\[ \mathbb{E} \left[ \exp(\Lambda_T) \right] \leq C_{K, T}. \] (3.25)

Combining (3.23) and (3.25), it only remains to prove that
\[ \mathbb{E} \left[ \sup_{[0, T]} \left( \exp (-\Lambda_t) |\eta_t|^{2p} \right) \right] \leq C_{K, T} |x - x'|^{2p}. \] (3.26)

By design, we derive from (3.19) with Itô’s formula that
\[ \exp(-\Lambda_t)|\eta_t|^{2p} \leq |x - x'|^{2p} + \int_0^t \exp(-\Lambda_s) dM_s \]
so that, denoting \( N_t \) the martingale term, with Burkholder-Davis-Gundy’s inequality,
\[ \mathbb{E} \left[ \sup_{[0, T]} \left( \exp (-\Lambda_t) |\eta_t|^{2p} \right) \right] \lesssim |x - x'|^{2p} + \mathbb{E} \left[ [N]_T^{1/2} \right]. \] (3.27)

This quadratic variation is given by
\[ [N]_T = 4p^2 \int_0^T \exp(-2\Lambda_t) |\eta_t|^{2p-2} \eta_t \cdot (C[\mu_s](X_t^\mu(x)) - C[\mu_s](X^\mu_s(x'))) \right|^2 dt \]
\[ \lesssim \int_0^T \exp(-2\Lambda_t) \lambda_t |\eta_t|^{4p} dt \lesssim \sup_{[0, T]} \left( \exp (-\Lambda_t) |\eta_t|^{2p} \right) \int_0^T \exp (-\Lambda_t) \lambda_t |\eta_t|^{2p} dt, \]
so that (3.27) leads to
\[ \mathbb{E} \left[ \sup_{[0, T]} \left( \exp (-\Lambda_t) |\eta_t|^{2p} \right) \right] \lesssim |x - x'|^{2p} + \mathbb{E} \left[ \sup_{[0, T]} \left( \exp (-\Lambda_t) |\eta_t|^{2p} \right) \right]^{1/2} \left( \int_0^T \mathbb{E} \left[ \exp (-\Lambda_t) \lambda_t |\eta_t|^{2p} \right] \right)^{1/2}. \]
The estimate (3.26) will therefore hold if we can establish
\[ \forall t \in [0, T], \quad \mathbb{E}\left[ \exp\left(-\Lambda t\right) \lambda_t |\eta_t|^{2p} \right] \leq C_K |x - x'|^{2p}. \] (3.28)

The integration by part formula gives
\[
d\left[ \exp\left(-\Lambda t\right) \lambda_t |\eta_t|^{2p} \right] = \exp\left(-\Lambda t\right) \left( |\eta_t|^{2p} d\lambda_t + \lambda_t d(|\eta_t|^{2p}) + d(\lambda_t, |\eta_t|^{2p})_t - \Lambda_t \lambda_t |\eta_t|^{2p} dt \right) = \exp\left(-\Lambda t\right) \left( |\eta_t|^{2p} d\lambda_t + \lambda_t d(|\eta_t|^{2p}) + d(\lambda_t, |\eta_t|^{2p})_t - \lambda_t^2 |\eta_t|^{2p} dt \right). \] (3.29)

Given that \( \mathbb{E}\left[ \exp\left(-\Lambda_0 \right) \lambda_0 |\eta_0|^{2p} \right] \leq C_K |x - x'|^{2p} \), it is enough to prove that the drift terms in (3.29) are all negative for \( \gamma \) chosen large enough.

Recalling (3.19), \( \lambda_t d(|\eta_t|^{2p}) \lesssim \lambda_t^2 |\eta_t|^{2p} dt + \lambda_t dM_t \).

Moreover, using the sublinearity Assumption 5, we easily get from the expression (3.20)
\[
d\lambda_t \lesssim \lambda_t + dm_t(x) + dm_t(x') + \int dm_t(y) d\mu_0(y), \] (3.30)
where
\[
dm_t(y) = 2\theta |X_t^\mu(y)|^{2\theta - 2} X_t^\mu(y) \cdot C[\mu_t](X_t^\mu(y)) d\beta_t, \] (3.31)
so that \( |\eta_t|^{2p} d\lambda_t \lesssim \lambda_t |\eta_t|^{2p} dt + |\eta_t|^{2p} (dm_t(x) + dm_t(x') + \int dm_t(y) d\mu_0(y)) \).

We conclude by noting that
\[
d(\lambda_t, |\eta_t|^{2p})_t = d\left[ m(x) + m(x') + \int m(y) d\mu_0(y), M \right] \lesssim \lambda_t |\eta_t|^{2p} dt \]
since for all \( y \in K, \)
\[
d\left[ m(y), M \right]_t = \left( 2\theta |X_t^\mu(y)|^{2\theta - 2} X_t^\mu(y) \cdot C[\mu_t](X_t^\mu(y)) \right) \left( 2p |\eta_t|^{2p - 2} \eta \cdot (C[\mu_t](X_t^\mu(x)) - C[\mu_t](X_t^\mu(x')) \right) dt \lesssim |X_t^\mu(y)|^{2\theta - 1} \left( 1 + |X_t^\mu(x)'| + |X_t^\mu(x)'|^{\theta} + \int |z|^{\theta} d\mu_t(z) \right) |\eta_t|^{2p} dt \lesssim \left( 1 + |X_t^\mu(x)'| + |X_t^\mu(x)'|^{\theta + 1} + |X_t^\mu(y)|^{\theta + 1} + \int |z|^{\theta + 1} d\mu_t(z) \right) |\eta_t|^{2p} dt \lesssim \left( 1 + |X_t^\mu(x)'|^{\theta} + |X_t^\mu(x)'|^{\theta + 1} + |X_t^\mu(y)|^{\theta} + \int |z|^{\theta} d\mu_t(z) \right) |\eta_t|^{2p} dt. \]

Note that \( \lambda_t \geq 1 \) so that \( \lambda_t \leq \lambda_t^2 \). The proof is complete. \( \square \)

### 3.4 Proof of the strong convergence

Now that the support estimate from Corollary 3.1 is acquired, we can prove Theorem 2.

Let us fix some \( T > 0 \) and \( p \geq 2 \). Let \( K \subset \mathbb{R}^d \) be a compact set, \( \mu_0 \in \mathcal{P}(\mathbb{R}^d) \) be a probability measure with support in \( K \), and \( (\mu^N_0) = \frac{1}{N} \sum_{i=1}^N \delta_{x_0^i} \) be a sequence of empirical measures with support in \( K \) such that
\[ W_p[\mu^N_0, \mu_0] \xrightarrow[N \to \infty]{} 0. \]

Letting \( (X^i_{t,N})_{t \in [0,T]} \) be the solution of (1.8) with initial data \( X^i_{t,N} = x_{0}^i, \) let us introduce \( \mu^N = \frac{1}{N} \sum_{i=1}^N \delta_{X^i_{t,N}} \) the empirical measure associated with the particle system, which is naturally of the transport form: \( \mu^N = (X^\mu^N)_* \mu^N_0 \).

Consequently, for \( N, M \geq 1 \), Proposition 3.2 gives, for all \( R > 0 \),
\[ \mathbb{E}\left[ \sup_{t \in [0,T]} W^p_\mu[\mu^N_t, \mu^M_t] \right] \leq C_{p,R,T} W^p_\mu[\mu^N_0, \mu^M_0] \]
where the stopping time is given by

$$\tau_{R}^{N,M} = \inf \left\{ t \geq 0, \sup_{x \in K} \left( |X_t^N(x)| + |X_t^M(x)| \right) \geq R \right\} \wedge T. \quad (3.32)$$

Let us in fact be more precise and use the inequality (3.11): introducing an optimal transport map $T^{N,M} : K \to K$ so that

$$W_p^{p[\mu_0^N, \mu_0^M]} = \int_K |x - T^{N,M}(x)|^p d\mu_0^N(x),$$

we have

$$W_p^{p[\mu^N, \mu^M]} \leq J_T^*= \int_K \sup_{t \in [0,T]} |X_t^N(x) - X_t^M(T^{N,M}(x))|^p d\mu_0^N(x), \quad (3.33)$$

with the inequality

$$\mathbb{E} \left[ J_T^*_{N,M} \right] \leq C_{p,T} W_p^{p[\mu_0^N, \mu_0^M]}.$$  

(3.34)

It then follows that

$$\mathbb{E} \left[ W_p^{p[\mu^N, \mu^M]} \right] \leq \mathbb{E} \left[ J_T^* \right] \leq \mathbb{E} \left[ J_T^*_{\tau_{R}^{N,M} = T} \right] + \mathbb{E} \left[ J_T^*_{\tau_{R}^{N,M} < T} \right] \quad (3.35)$$

$$\leq \mathbb{E} \left[ J_T^*_{\tau_{R}^{N,M}} \right] + C_{p,T} \mathbb{E} \left[ \left( |X_t^N(x)|^p + |X_t^M(T^{N,M}(x))|^p \right) \sup_{t \in [0,T]} \sup_{x \in K} |X_t^N(x)| \right]^{1/2} \sup_{t \in [0,T]} \sup_{x \in K} |X_t^N(x)| \right]^{1/2}.$$   

Therefore, using the bound from Corollary 3.1,

$$\mathbb{E} \left[ W_p^{p[\mu^N, \mu^M]} \right] \leq C_{p,T} W_p^{p[\mu_0^N, \mu_0^M]} + C_{p,K} \left( \tau_{R}^{N,M} < T \right)^{1/2}.$$   

Markov’s inequality gives

$$\mathbb{P} \left( \tau_{R}^{N,M} < T \right) \leq \mathbb{P} \left( \sup_{t \in [0,T]} \sup_{x \in K} \left( |X_t^N(x)| + |X_t^M(x)| \right) \geq R \right) \leq C_{p,K} R^{-2}.$$   

We conclude that

$$\limsup_{N,M \to \infty} \mathbb{E} \left[ W_p^{p[\mu^N, \mu^M]} \right] \leq C_{p,K} R^{-1} \xrightarrow{R \to 0} 0.$$   

This shows that $(\mu^N)_{N \geq 1}$ is a Cauchy sequence, hence converges in the complete space $L^p(\Omega; \mathcal{P}_p(\mathcal{C}))$ to some $\mu$.

Let us now prove that the limiting measure $\mu$ is also of the transport form and therefore satisfies the SPDE (1.11) with initial data $\mu_0$ (according to Proposition 3.1).

Denoting $\nu = (X^\mu)^* \mu_0 \in \mathcal{P}_p(\mathcal{C})$, we may slightly adapt the proof of Proposition 3.2 to obtain an estimate of $W_p^{p[\mu^N, \nu]}$. Indeed, introducing an optimal transport map $T^{N} : K \to K$ so that

$$W_p^{p[\mu_0^N, \mu_0]} = \int_K |x - T^N(x)|^p d\mu_0(x),$$

26
we have this time
\[
W_p^p[\mu^N, \nu] \leq I_T^* := \int_K \sup_{t \in [0,T]} |X_t^\mu^N(x) - X_t^\nu(T^N(x))|^p \, d\mu_0(x) \tag{3.36}
\]
and we are naturally led to study \( \eta_t(x) = X_t^\mu^N(x) - X_t^\nu(T^N(x)) \). Setting \( p = 2 \) for simplicity, calculations give, as in (3.7),
\[
d|\eta_t|_{L^2_R}(x)^2 \leq C_R |\eta_{t\wedge \tau_R}(x)|^2 + W_2^2[\mu_{t\wedge \tau_R}, \mu_{t\wedge \tau_R}] \, dt + dM_{t\wedge \tau_R}(x)
\]
where the stopping time is defined as
\[
\tau_R := \inf \left\{ t \geq 0, \sup_{x \in K} \left( |X_t^\mu^N(x)| + |X_t^\nu(x)| \right) \geq R \right\} \wedge T.
\]
We can now carry on as in the proof of Proposition 3.2 to obtain the estimate
\[
\mathbb{E} \left[ I_{\tau_R}^N \right] \leq C_{p,R,T} \left( W_p^p[\mu^N_0, \mu_0] + \mathbb{E} \left[ W_p^p[\mu^N, \mu] \right] \right) \leq C_{p,R,T} \mathbb{E} \left[ W_p^p[\mu^N, \mu] \right]. \tag{3.37}
\]
From (3.36) and (3.37), using the same method as in (3.35), since \( \mu_0^N, \mu_0 \) are supported in \( K \subset \mathbb{R}^d \), we are led to
\[
\mathbb{E} \left[ W_p^p[\mu^N, \nu] \right] \leq C_{p,R,T} \mathbb{E} \left[ W_p^p[\mu^N, \mu] \right] + C_{p,K} \mathbb{P} \left( \tau_R < T \right)^{1/2}.
\]
Sending \( N, R \to \infty \) in the same fashion as before, we conclude that \( \mathbb{E} \left[ W_p^p[\mu, \nu] \right] = 0 \), that is \( \mu = \nu \) almost surely: therefore \( \mu \) is of the transport form.

Lastly, the uniqueness of a solution of the transport form for \( \mu_0 \) supported in \( K \subset \mathbb{R}^d \) is again obtained in the same way: given \( \mu = (X^\mu)^* \mu_0 \) and \( \tilde{\mu} = (X^{\tilde{\mu}})^* \mu_0 \) two solutions of the transport form, we may apply Proposition 3.2 (or more precisely equation (3.11)) and the method used in (3.35) to obtain
\[
\mathbb{E} \left[ W_p^p[\mu, \tilde{\mu}] \right] \leq C_{p,K} \mathbb{P} \left( \tau_R < T \right)^{1/2}
\]
with
\[
\tau_R := \inf \left\{ t \geq 0, \sup_{x \in K} \left( |X_t^\mu(x)| + |X_t^{\tilde{\mu}}(x)| \right) \geq R \right\} \wedge T.
\]
We may then send \( R \to \infty \) to get \( \mu = \tilde{\mu} \) almost surely. This concludes the proof of Theorem 2.
