LB-4. Phase 3 Randomized, Controlled Trial of Switching to Fixed-dose Bictegravir/Emtirabatbine/Tenofovir Alafenamide (B/F/TAF) from Boosted Protease Inhibitor-based Regimens in Virologically Suppressed Adults: Week 48 Results

Eric Daar, MD;1 Edwin DeJesus, MD;2 Peter Ruane, MD;3 Gordon Crofoot, MD;4 Gonda Ouchi, MD;1 Marie-Cecile Jiol, MD;1 Ingrid Michel, MD, PhD;1 Ellen Koenig, MD;1 Ya-Pei Liu, PhD5;6 Kristen Andreaa, PhD7;5 Hiba Graham, Pharm D8;5 Andrew Cheng, MD PhD5;6 Hal Martin, MD, MPH9;6 Erin Quirk, MD10;6 11142 W Carson St., Harbor-UCLA Medical Center, Torrance, California; 2The Florida Immunology, Orlando, Florida; 3Bailey Clinical Research Group, Inc., Los Angeles, California; 4The Crofoot Research Center, Houston, Texas; 5Midland Florida Clinical Research Center, LLC, Deland, Florida; 6Howard Brown Health Center, Chicago, Illinois; 7Department of Medicine I, Bonn University Hospital, Venuesungs, Germany; 8Department of Infectious Diseases, Saint-Louis Hospital, Paris, France; 9Medicine, Distin Estudio Virologico, Santo Domingo, Dominican Republic; 10Gilead Sciences, Foster City, California

Session: 228. Late Breaker Oral Abstracts Saturday, October 7, 2017: 10:30 AM

Background. Boosted protease inhibitor regimens (bPIs) are effective and often used in HIV-infected individuals with difficulties with adherence, but they can have drug–drug interactions and GI adverse effects. Bictegravir (B), a novel, potent integrase strand transfer inhibitor with a high admission to resistance and low potential for drug–drug interactions, was coformulated with the recommended nucleoside reverse transcriptase inhibitor backbone emtricitabine (FTC)/tenofovir alafenamide (TAF/bPI/TAF) and demonstrated high efficacy and tolerability in randomized studies in treatment-naïve adults. We report the results of a randomized phase 1 study assessing efficacy and safety of switching to B/F/TAF from a multi-tablet regimen containing a bPI.

Methods. HIV-infected adults suppressed on regimens of boosted atazanavir (ATV) or darunavir (DRV) + abacavir/ lamivudine (ABC/3TC) or FTC/tenofovir disoproxil fumarate (TDF) as monotherapy or as a switch to open-label coformulated B/F/TAF (50/200/25 mg) once daily. Primary endpoint was proportion with HIV-1 RNA <50 copies/mL at W48 (FDA snap-shot). Noninferiority was assessed with 95.002% confidence intervals (CI) using a margin of 4%. Secondary endpoints included proportion with HIV-1 RNA <50 copies/mL and safety measures at W48.

Results. A total of 577 participants were randomized and treated with B/F/TAF (n = 290) or current bPI regimens (n = 287): 17% women, 26% Black, median age 48 years. Most were receiving a bPI with FTC/TDF (85%) at screening. At W48, switching to B/F/TAF was noninferior to continuing bPI with 1.7% in each group having HIV-1 RNA ≥50 copies/mL (difference −0.0%; 95.002% CI −2.5% to 2.5%, P = 1.00); the proportion with HIV-1 RNA <50 copies/mL was 92.1% in B/F/TAF vs. 88.9% in bPI. No treatment failure, defined as persistent infection relapse or new infection, occurred in ~50% of cases. Adjunctive ethanol lock and safety measures at W48.

Conclusion. Adults switching to B/F/TAF from a boosted PI maintained high rates of virologic suppression and bPI/TAF was safe and well tolerated.

LB-5. The SEP-SEQ Trial: Clinical Validation of the Karius Plasma Next-Generation Sequencing Test for Pathogen Detection in Septic Patients

Simone Thay, PhD;1 Hon Seng, BS;2 Desiree Hollemon, MSN, MPH;3 David Hong, MD;4 Timothy Blawwakamp, PhD;4 Mickey Kertesz, PhD;5 Carne Ho, MD;6 Rosean Mara, BS;6 James Quinn, MD;6 and Samuel Yang, MD.7 Emergency Medicine, Stanford University Medical Center, Stanford, California; 8Karius, Inc., Redwood City, California

Session: 228. Late Breaker Oral Abstracts Saturday, October 7, 2017: 10:30 AM

Background. Sepsis is a leading cause of death and can be caused by a wide range of potential pathogens. In up to 40% of cases, a causative pathogen is never identified. There is a need for improved diagnostic tests that can accurately identify the breadth of pathogens involved.

Methods. We enrolled a prospective cohort of patients presenting to the hospital with signs and symptoms of sepsis. Plasma samples were collected for NGS testing at time of initial blood culture. Extracted plasma cell-free DNA was sequenced, human sequences removed and remaining reads aligned against a pathogen database consisting of viruses, bacteria, and eukaryotic pathogens. Relative abundance was estimated; pathogens present at high statistical significance were identified. NGS results were compared with a composite reference standard of all microbiology testing performed within 7 days of admission and clinical diagnosis.

Results. Of 286 patients enrolled, plasma NGS identified potential pathogens in 60.1% (172 of 286) of septic subjects including DNA viruses, bacteria (including fastidious/unculturable bacteria like Mycobacterium tuberculosis), and fungi. In contrast, only 19.4% (54 of 286) subjects had a positive initial blood culture and 38.1% (109 of 286) had a potential infectious etiology identified using a composite microbiology laboratory standard. The NGS plasma assay had a positive agreement of 86.7% (39 of 45) and 79.3% (78 of 98) compared with initial blood culture (after excluding contaminants) and the composite laboratory reference standard, respectively. After clinical adjudication, 81.4% (140 of 172) of the positive plasma NGS results were deemed to be consistent with the septic event. Of the remaining 32 subjects, 15 had NGS results that were plausible causes of sepsis but clinical were insufficient to confirm this.

Conclusion. With a single blood draw, the Karius plasma NGS assay identified a broad range of pathogens in septic patients three times more often than blood culture and more often than all microbiology tests combined. This plasma NGS test can identify a viruses, bacteria, and eukaryotic pathogens which can provide valuable information to help clinicians better target antimicrobial therapy for patients with sepsis.

Session: 228. Late Breaker Oral Abstracts Saturday, October 7, 2017: 10:30 AM

Background. Central-line associated bloodstream infection (CLABSI) commonly affects children with cancer and hematological disorders, with significant attributable costs and morbidity. Treatment failure, comprising persistent infection, infection relapse or new infection, occurs in ~50% of cases. Adjunctive ethanol lock therapy (ELT) has been proposed to prevent failure, but has never been tested in a prospective controlled study.

Methods. A prospective single-center, double-blind, block-randomized, placebo-controlled trial of ELT (70% ethanol in water) for CLABSI, given as treatment (2 hours per lumen per day) for 5 days, followed by secondary prophylaxis (2 hours per lumen up to 3 days per week) for 24 weeks, in children with oncologic or hematologic disorders (NCT01472965). Risk of treatment failure was compared between intervention and control groups according to proportional and cumulative incidence models.
using intention-to-treat and per-protocol analyses. The study was discontinued at a pre-specified futility analysis.

Results. Of 94 evaluable participants, 48 were randomized to ELT and 46 to placebo; groups were similar at baseline for all measured variables. Forty-one (43.6%) participants had treatment failure (11 early failure, 9 relapse, and 21 reinfection). There was no difference between patients receiving ELT or placebo for risk of treatment failure (43.8% vs. 43.5%; P = 0.9) or for cumulative incidence of treatment failure in intention to treat (Figure 1) and per-protocol analyses (Figure 2). Catheter occlusion was significantly more common in participants receiving ethanol (58.3% vs. 32.6%, P = 0.01) but other adverse events, including LFT elevations (14.6% vs. 26.1%) and infusion reactions (18.8% vs. 8.7%), were not significantly different between groups.

**Conclusion.** Although observational studies suggested ELT might be effective for treatment of CLABSIs in pediatric oncology, we found no benefit in treatment outcome and an increase in adverse effects. These results may not apply to patients receiving dialysis or with fungal CLABSIs as these were not well-represented. Routine use of ELT for CLABSIs in children with oncologic or hematologic disorders is not recommended.

**Session:** 228. Late Breaker Oral Abstracts

**Background.** Increased hydration is commonly recommended as a preventive measure for women with recurrent acute uncomplicated cystitis (rAUC), but supportive data are sparse. The aim of this study was to assess the efficacy of increased daily water intake on the frequency of rAUC in premenopausal women.

**Methods.** 140 healthy premenopausal asymptomatic women drinking less than 1.5 L of total fluid daily (24 hours) and suffering from rAUC (3 episodes in the past year) were randomized to receive, in addition to their usual daily fluid intake, either 1.5 L water daily (water group) or no additional fluids (control group), for 12 months. Assessments of daily water and total fluid intake, urine volume and osmolality, number of urine voids, and occurrence of AUC symptoms and a reminder to notify investigators of any such symptoms were performed at baseline, 6- and 12-month clinic visits in addition to monthly telephone calls. The primary outcome was frequency of rAUC episodes (1 AUC symptom and 10 CFU/mL of a uropathogen in voided urine) over 12 months.

**Results.** Between baseline and 12 months follow-up, the water group, compared with the control group, had statistically significant increases in mean daily water intake (1.15 L vs. 0.10 L), total fluid intake (1.65 vs. 0.03 L), urine volume (1.40 vs. 0.04 L), and number of urine voids (2.2 vs. −0.2), and a decrease in urine osmolality (−408 vs. −35 mOsm/Kg). The mean number of rAUC episodes in the water group was significantly less than in the control group (1.6 vs. 3.1; odds ratio 0.52, 95% CI 0.46–0.69, P < 0.0001) (figure shows cumulative sum of AUC episodes over 12 months in both study groups). The mean number of antimicrobial regimens used to treat AUC events was 1.8 in the water group vs. 3.5 in the control group (P < 0.0001). In addition, the mean number of days to first rAUC and the mean number of days between rAUC episodes was longer in the water group compared with the control group (148 vs. 93, P = 0.0005 and 143 vs. 85, P < 0.0001, respectively).

**Conclusions.** Our results provide strong evidence that increased water intake is an effective antimicrobial-sparing preventive strategy for women with rAUC. Increasing daily water intake by approximately 1.5 L reduced rAUC episodes by 48% and antimicrobial regimens by 47% over 12 months.

**LB-8. Sorting the Wheat from the Chaff: Vaccine-Associated Rash Illness Occurring amidst a Large Measles Outbreak—Minnesota, 2017**

Karen Martin, MPH1; Raaj Mody, MD, MPH2,3; Malini Desilva, MD, MPH4; Emily Banerjee, MPH5; Anna Strain, PhD1; Stacy Holzbauer, DVM, MPH, DACVPVM6; Cynthia Kenyon, MPH1; Melissa McMahon, MPH1; Paul Rota, PhD1; Paul Gastanaduy, MD, MPH1; Miriam Muscophat, MPH1; Victoria Hall, DVM MS1 and Kristen Ehresmann, MS, RN1; Minnesota Department of Health, St. Paul, Minnesota; 2Division of State and Local Readiness, Office of Public Health Preparedness and Response, Centers for Disease Control and Prevention, Atlanta, Georgia; 3Division of Viral Diseases, National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia; 4Epidemic Intelligence Service Program, Centers for Disease Control and Prevention, Atlanta, Georgia

**Session:** 228. Late Breaker Oral Abstracts

**Background** During April–June 2017, Minnesota experienced the state’s largest measles outbreak in 27 years. A vaccination campaign was implemented. Numerous vaccine-associated rash illnesses (VARI) were detected. VARI is non-contagious, but difficult to distinguish from measles clinically. Often, public health control measures need to be implemented before wild-type measles can be differentiated from VARI by viral genotyping. We compared clinical characteristics of VARI and confirmed measles cases to inform testing practices.

**Methods.** We defined measles cases per the Council of State and Territorial Epidemiologists. VARI was defined as a rash occurring in a person within 21 days after receipt of measles, mumps, and rubella (MMR) vaccine, and in whom a measles vaccine strain (genotype A) was detected in nasso/oro-pharyngeal swab or urine samples. Minnesota’s immunization information system monitored MMR doses administered. We collected clinical information through routine case investigation.

**Results.** Over 42,000 MMR doses above expected were administered during the outbreak. We identified 71 measles cases and 30 VARI. The median age of VARI patients was 1.2 years (range 10 months–48 years) and for measles cases 2.8 years (range 3 months–57 years). VARI diagnosis increased with rising MMR administration (figure); rash onset occurred a median of 11 (range 7–18) days after MMR receipt. Most VARI (97%) occurred following first MMR dose. The presence of fever was similar among VARI and measles cases (97% of VARI vs. 100% of measles cases; P = 0.12), but differences were seen in the proportion with cough (30% vs. 96%; P < 0.001), conjunctivitis (23% vs. 68%; P < 0.001), and exposure to infectious measles cases (0% vs. 96%).
