Thinning, Entropy and the Law of Thin Numbers

Peter Harremoës, Oliver Johnson and Ioannis Kontoyiannis

Abstract

Rényi’s thinning operation on a discrete random variable is a natural discrete analog of the scaling operation for continuous random variables. The properties of thinning are investigated in an information-theoretic context, especially in connection with information-theoretic inequalities related to Poisson approximation results. The classical Binomial-to-Poisson convergence (sometimes referred to as the “law of small numbers”) is seen to be a special case of a thinning limit theorem for convolutions of discrete distributions. A rate of convergence is provided for this limit, and nonasymptotic bounds are also established. This development parallels, in part, the development of Gaussian inequalities leading to the information-theoretic version of the central limit theorem. In particular, a “thinning Markov chain” is introduced, and it is shown to play a role analogous to that of the Ornstein-Uhlenbeck process in connection to the entropy power inequality.

I. Introduction

Approximating the distribution of a sum of weakly dependent discrete random variables by a Poisson distribution is an important and well-studied problem in probability; see [1] and the references therein for an extensive account. Strong connections between these results and information-theoretic techniques were established [15][24]. In particular, for the special case of approximating a binomial distribution by a Poisson, some of the sharpest results to date are established using a combination of the techniques [15][24] and Pinsker’s inequality [7][10][18]. Earlier work on information-theoretic bounds for Poisson approximation is reported in [36][21][28].

The thinning operation, which we define next, was introduced by Rényi in [29], who used it to provide an alternative characterization of Poisson measures.

Definition 1: Given $\alpha \in [0, 1]$ and a discrete random variable $X$ with distribution $P$ on $\mathbb{N}_0 = \{0, 1, \ldots\}$, the $\alpha$-thinning of $P$ is the distribution $T_\alpha(P)$ of the sum,

$$\sum_{x=1}^{X} B_x, \quad \text{where } B_1, B_2 \ldots \sim \text{i.i.d. Bern}(\alpha),$$

(1)

where the random variables $\{B_x\}$ are independent and identically distributed (i.i.d.) each with a Bernoulli distribution with parameter $\alpha$, denoted Bern$(\alpha)$, and also independent of $X$. [As usual, we take the empty sum $\sum_{x=1}^{0} (\cdot)$ to be equal to zero.] An explicit representation of $T_\alpha(P)$ can be given as,

$$T_\alpha(P)(z) = \sum_{x=z}^{\infty} P(x) \left(\frac{x}{z}\right)^\alpha (1-\alpha)^{x-z}, \quad z \geq 0.$$ 

(2)

When it causes no ambiguity, the thinned distribution $T_\alpha(P)$ is written simply $T_\alpha P$.

For any random variable $X$ with distribution $P$ on $\mathbb{N}_0$, we write $P^{*n}$ for the $n$-fold convolution of $P$ with itself, i.e., the distribution of the sum of $n$ i.i.d. copies of $X$. For example, if $P \sim \text{Bern}(p)$, then $P^{*n} \sim \text{Bin}(n, p)$, the binomial distribution with parameters $n$ and $p$. It is easy to see that its $(1/n)$-thinning, $T_{1/n}(P^{*n})$, is simply $\text{Bin}(n, p/n)$; see Example 6 below. Therefore, the classical Binomial-to-Poisson convergence result – sometimes referred to as the “law of small numbers” – can be phrased as saying that, if $P \sim \text{Bern}(p)$, then,

$$T_{1/n}(P^{*n}) \rightarrow \text{Po}(p), \quad \text{as } n \rightarrow \infty,$$

(3)

where Po$(\lambda)$ denotes the Poisson distribution with parameter $\lambda > 0$.

One of the main points of this work is to show that this result holds for very wide class of distributions $P$, and to provide conditions under which several stronger and more general versions of (3) can be obtained. We refer to results of the form (3) as laws of thin numbers.

Section II contains numerous examples that illustrate how particular families of random variables behave on thinning, and it also introduces some of the particular classes of random variables that will be considered in the rest of the paper. In Sections III and IV several versions of the law of thin numbers are formulated; first for i.i.d. random variables in Section III and then for general classes of (not necessarily independent or identically distributed) random variables in Section IV. For example, in the simplest case where $Y_1, Y_2, \ldots$ are i.i.d. with distribution $P$ on $\mathbb{N}_0$ and with mean $\lambda$, so that the distribution of their sum, $S_n = Y_1 + Y_2 + \cdots + Y_n$, is $P^{*n}$, Theorem 14 shows that,

$$D \left( T_{1/n}(P^{*n}) \| \text{Po}(\lambda) \right) \rightarrow 0, \quad \text{as } n \rightarrow \infty,$$

(4)
as long as $D(P||\text{Po}(\lambda)) < \infty$, where, as usual, $D(P||Q)$ denotes the information divergence, or relative entropy, from $P$ to $Q$.

$$D(P||Q) = \sum_{z=0}^{\infty} P(z) \log \frac{P(z)}{Q(z)}.$$ 

Note that, unlike most classical Poisson convergence results, the law of thin numbers in (4) proves a Poisson limit theorem for the sum of a single sequence of random variables, rather than for a triangular array.

It may be illuminating to compare the result (4) with the information-theoretic version of the central limit theorem (CLT); see, e.g., [2][19]. Suppose $Y_1, Y_2, \ldots$ are i.i.d. continuous random variables with density $f$ on $\mathbb{R}$, and with zero mean and unit variance. Then the density of their sum $S_n = Y_1 + Y_2 + \cdots + Y_n$, is the $n$-fold convolution $f^{*n}$ of $f$ with itself. Write $\Sigma_\alpha$ for the standard scaling operation in the CLT regime: If a continuous random variable $X$ has density $f$, then $\Sigma_\alpha(f)$ is the density of the scaled random variable $\sqrt{\alpha}X$, and, in particular, the density of the standardized sum $\frac{1}{\sqrt{n}}S_n$ is $\Sigma_{1/n}(f^{*n})$. The information-theoretic CLT states that, if $D(f||\phi) < \infty$, we have,

$$D\left(\Sigma_{1/n}(f^{*n})||\phi\right) \rightarrow 0, \quad \text{as } n \rightarrow \infty, \quad (5)$$

where $\phi$ is the standard Normal density. Note the close analogy between the statements of the law of thin numbers in (4) and the CLT in (5).

Before describing the rest of our results, we mention that there is a significant thread in the literature on thinning limit theorems and associated results for point processes. Convergence theorems of the “law of thin numbers” type, as in (3) and (4), were first examined in the context of queueing theory by Palm [27] and Khinchin [22], while more general results were established by Grigelionis [14]. See the discussion in the text, [9, pp. 146-166], for details and historical remarks; also see the comments following Theorem 16 in Section IV. More specifically, this line of work considered asymptotic results, primarily in the sense of weak convergence, for the distribution of a superposition of the sample paths of independent (or appropriately weakly dependent) point processes. Here we take a different direction and, instead of considering the full infinite-dimensional distribution of a point process, we focus on finer results – e.g., convergence in information divergence and non-asymptotic bounds – for the one-dimensional distribution of the thinned sum of integer-valued random variables.

With these goals in mind, before examining the finite-$n$ behavior of $T_{1/n}(P^{*n})$, in Section V we study a simpler but related problem, on the convergence of a continuous-time “thinning” Markov chain on $\mathbb{N}_0$. In the present context, this chain plays a role parallel to that of the Ornstein-Uhlenbeck process in the context of Gaussian convergence and the entropy power inequality [31] [32] [25]. We show that the thinning Markov chain has the Poisson law as its unique invariant measure, and we establish its convergence both in total variation and in terms of information divergence. Moreover, in Theorem [28] we characterize precisely the rate at which it converges to the Poisson law in terms of the $\chi^2$ distance, which also leads to an upper bound on its convergence in information divergence. A new characterization of the Poisson distribution in terms of thinning is also obtained. The main technical tool used here is based on an examination of the $L^2$ properties of the Poisson-Charlier polynomials in the thinning context.

1 Throughout the paper, log denotes the natural logarithm to base $e$, and we adopt the usual convention that $0 \log 0 = 0$. 
In Section [VI] we give both asymptotic and finite-n bounds on the rate of convergence for the law of thin numbers. Specifically, we employ the *scaled Fisher information* functional introduced in [24] to give precise, explicit bounds on the divergence, \( D(T_{1/n}(P^*) \| \text{Po}(\lambda)) \). An example of the type of result we prove is the following: Suppose \( X \) is an ultra bounded (see Definition 8 in Section [II]) random variable, with distribution \( P \), mean \( \lambda \), and finite variance \( \sigma^2 \neq \lambda \). Then,

\[
\limsup_{n \to \infty} n^2 D \left( T_{1/n}(P^*) \| \text{Po}(\lambda) \right) \leq 2c^2,
\]

for a nonzero constant \( c \) we explicitly identify; cf. Corollary [32].

Similarly, in Section [VIII] we give both finite-n and asymptotic bounds on the law of small numbers in terms of the total variation distance, \( \|T_{1/n}(P^*) - \text{Po}(\lambda)\| \), between \( T_{1/n}(P^*) \) and the \( \text{Po}(\lambda) \) distribution. In particular, Theorem [36] states that if \( X \sim P \) has mean \( \lambda \) and finite variance \( \sigma^2 \), then, for all \( n \),

\[
\|T_{1/n}(P^*) - \text{Po}(\lambda)\| \leq \frac{1}{n^{1/2}} + \frac{\sigma}{n^{1/2}} \min \left\{ 1, \frac{1}{2\lambda^{1/2}} \right\}.
\]

A closer examination of the monotonicity properties of the scaled Fisher information in relation to the thinning operation is described in Section [VII]. Finally, Section [IX] shows how the idea of thinning can be extended to compound Poisson distributions. The Appendix contains the proofs of some of the more technical results.

Finally we mention that, after the announcement of the present results in [17], Yu [35] also obtained some interesting, related results. In particular, he showed that the conditions of the strong and thermodynamic versions of the law of thin numbers (see Theorems [14] and [12]) can be weakened, and he also provided conditions under which the convergence in these limit theorems is monotonic in \( n \).
II. EXAMPLES OF THINNING AND DISTRIBUTION CLASSES

This section contains several examples of the thinning operation, statements of its more basic properties, and the definitions of some important classes of distributions that will be play a central role in the rest of this work. The proofs of all the lemmas and propositions of this section are given in the Appendix.

Note, first, two important properties of thinning that are immediate from its definition:

1. The thinning of a sum of independent random variables is the convolution of the corresponding thinnings.

2. For all $\alpha, \beta \in [0, 1]$ and any distribution $P$ on $\mathbb{N}_0$, we have,

$$T_\alpha(T_\beta(P)) = T_{\alpha\beta}(P).$$

**Example 2:** Thinning preserves the Poisson law, in that $T_\alpha(Po(\lambda)) = Po(\alpha \lambda)$. This follows from (2), since,

$$T_\alpha(Po(\lambda))(z) = \sum_{x=z}^{\infty} Po(\lambda, x) \left(\frac{x}{z}\right) \alpha^x (1 - \alpha)^{x-z}$$

$$= \sum_{x=z}^{\infty} \frac{\lambda^x}{x!} e^{-\lambda} \left(\frac{x}{z}\right) \alpha^x (1 - \alpha)^{x-z}$$

$$= \frac{e^{-\lambda}}{z!} (\alpha \lambda)^z \sum_{x=z}^{\infty} \frac{(\lambda(1 - \alpha))^{x-z}}{(x-z)!}$$

$$= \frac{e^{-\lambda}}{z!} (\alpha \lambda)^z e^{\lambda(1-\alpha)}$$

$$= Po(\alpha \lambda, z),$$

where $Po(\lambda, x) = e^{-\lambda} \lambda^x / x!$, $x \geq 0$, denotes the Poisson mass function.

As it turns out, the factorial moments of a thinned distribution are easier to work with than ordinary moments. Recall that the $k$th factorial moment of $X$ is $E[X^k]$, where $x^k$ denotes the falling factorial,

$$x^k = x(x-1) \cdots (x-k+1) = \frac{x!}{(x-k)!}.$$  

The factorial moments of an $\alpha$-thinning are easy to calculate:

**Lemma 3:** For any random variable $Y$ with distribution $P$ on $\mathbb{N}_0$ and for $\alpha \in (0, 1)$, writing $Y_\alpha$ for a random variable with distribution $T_\alpha P$:

$$E[Y_\alpha^k] = \alpha^k E[Y^k].$$

That is, thinning scales factorial moments in the same way as ordinary multiplication scales ordinary moments.

We will use the following result, which is a multinomial version of Vandermonde’s identity and is easily proved by induction. The details are omitted.

**Lemma 4:** The falling factorial satisfies the multinomial expansion, i.e., for any positive integer $y$, all integers $x_1, x_2, \ldots, x_y$, and any $k \geq 1$,

$$\left( \sum_{i=1}^{y} x_i \right)^k = \sum_{k_1, k_2, \ldots, k_y : k_1+k_2+\cdots+k_y=k} \binom{k}{k_1 \ k_2 \ \cdots \ k_y} \prod_{i=1}^{y} x_i^{k_i}.$$
The following is a basic regularity property of the thinning operation.

**Proposition 5:** For any $\alpha \in (0, 1)$, the map $P \mapsto T_\alpha(P)$ is injective.

**Example 6:** Thinning preserves the class of Bernoulli sums. That is, the thinned version of the distribution of a finite sum of independent Bernoulli random variables (with possibly different parameters) is also such a sum. This follows from property 1 stated in the beginning of this section, combined with the observation that the $\alpha$-thinning of the Bern$(p)$ distribution is the Bern$(\alpha p)$ distribution. In particular, thinning preserves the binomial family: $T_\alpha(\text{Bin}(n, p)) = \text{Bin}(n, \alpha p)$.

**Example 7:** Thinning by $\alpha$ transforms a geometric distribution with mean $\lambda$ into a geometric distribution with mean $\alpha \lambda$. Recalling that the geometric distribution with mean $\lambda$ has point probabilities, $\text{Geo}(\lambda, x) = \frac{1}{1+\lambda} \left( \frac{\lambda}{1+\lambda} \right)^x$, $x = 0, 1, \ldots$, using (2),

\[
T_\alpha \text{Geo}(\lambda)(z) = \sum_{x=z}^{\infty} \frac{1}{1+\lambda} \left( \frac{\lambda}{1+\lambda} \right)^x \frac{\lambda^z (1-\alpha)^{x-z}}{z!} \\
= \frac{1}{(1+\lambda)z!} \left( \frac{\alpha \lambda}{1+\lambda} \right)^z \sum_{x=z}^{\infty} \left( \frac{\lambda(1-\alpha)}{1+\lambda} \right)^{x-z} x^z \\
= \frac{1}{(1+\lambda)z!} \left( \frac{\alpha \lambda}{1+\lambda} \right)^z z! \left( 1 - \frac{\lambda(1-\alpha)}{1+\lambda} \right)^{-z-1} \\
= \text{Geo}(\alpha \lambda, z).
\]

The sum of $n$ i.i.d. geometrics has a negative binomial distribution. Thus, in view of this example and property 1 stated in the beginning of this section, the thinning of a negative binomial distribution is also negative binomial.

Partly motivated by these examples, we describe certain classes of random variables (some of which are new). These appear as natural technical assumptions in the subsequent development of our results. The reader may prefer to skip the remainder of this section and only refer back to the definitions when necessary.

**Definition 8:**

1) A **Bernoulli sum** is a distribution that can be obtained from the sum of finitely many independent Bernoulli random variables with possibly different parameters. The class of Bernoulli sums with mean $\lambda$ is denoted by $\text{Ber}(\lambda)$ and the the union $\bigcup_{\mu \leq \lambda} \text{Ber}(\lambda)$ is denoted by $\text{Ber}^\leq(\lambda)$.

2) A distribution $P$ satisfying the inequality

\[
\log \frac{P(j)}{P(\lambda, j)} \geq \frac{1}{2} \log \frac{P(j-1)}{P(\lambda, j-1)} + \frac{1}{2} \log \frac{P(j+1)}{P(\lambda, j+1)};
\]

is said to be **ultra log-concave (ULC)**; cf. [20]. The set of ultra log-concave distributions with mean $\lambda$ shall be denoted $\text{ULC}(\lambda)$, and we also write $\text{ULC}^\leq(\lambda)$ for the union $\bigcup_{\mu \leq \lambda} \text{ULC}(\lambda)$. Note that (8) is satisfied for a single value of $\lambda > 0$ if and only if it is satisfied for all $\lambda > 0$.

3) The distribution of a random variable $X$ that satisfies $E[X^{k+1}] \leq \lambda E[X^k]$ for all $k \geq 0$ will be said to be **ultra bounded** (UB) with ratio $\lambda$. The set of ultra bounded distributions with this ratio is denoted $\text{UB}(\lambda)$. 

4) The distribution of a random variable $X$ satisfying $E[X^k] \leq \lambda^k$ for all $k \geq 0$ will be said to be Poisson bounded (PB) with ratio $\lambda$. The set of Poisson bounded distributions with this ratio is denoted $PB(\lambda)$.

5) A random variable will be said to be ULC, UB or PB, if its distribution is ULC, UB or PB, respectively.

First we mention some simple relationships between these classes. Walkup [33] showed that if $X \sim P \in ULC(\lambda)$ and $Y \sim Q \in ULC(\mu)$ then $X + Y \sim P * Q \in ULC(\lambda + \mu)$. Hence $Ber(\lambda) \subseteq ULC(\lambda)$. In [20] it was shown that, if $P \in ULC(\lambda)$, then $T_\alpha P \in ULC(\alpha \lambda)$. Clearly, $UB(\lambda) \subseteq PB(\lambda)$. Further, $P$ is Poisson bounded if and only if the $\alpha$-thinning $T_\alpha P$ is Poisson bounded, for some $\alpha > 0$. The same holds for ultra boundedness.

**Proposition 9:** In the notation of Definition 8 $ULC(\lambda) \subseteq UB(\lambda)$. That is, if the distribution of $X$ is in $ULC(\lambda)$ then $E[X^{k+1}] \leq \lambda E[X^k]$.

The next result states that the PB and UB properties are preserved on summing and thinning.

**Proposition 10:**
(a) If $X \sim P \in PB(\lambda)$ and $Y \sim Q \in PB(\mu)$ are independent, then $X + Y \sim P * Q \in PB(\lambda + \mu)$ and $T_\alpha P \in PB(\alpha \lambda)$.
(b) If $X \sim P \in UB(\lambda)$ and $Y \sim Q \in UB(\mu)$ are independent, then $X + Y \sim P * Q \in UB(\lambda + \mu)$ and $T_\alpha P \in UB(\alpha \lambda)$.

Formally, the above discussion can be summarized as,

$$Ber^{\leq}(\lambda) \subseteq ULC^{\leq}(\lambda) \subseteq UB(\lambda) \subseteq PB(\lambda).$$

Finally, we note that each of these classes of distributions is “thinning-convex,” i.e., if $P$ and $Q$ are element of a set then $T_\alpha(P) * T_{1-\alpha}(Q)$ is also an element of the same set. In particular, thinning maps each of these sets into itself, since $T_\alpha(P) = T_\alpha(P) * T_{1-\alpha}(\delta_0)$ where $\delta_0$, the point mass at zero, has $\delta_0 \in Ber^{\leq}(\lambda)$. 
III. LAWS OF THIN NUMBERS: THE I.I.D. CASE

In this section we state and prove three versions of the law of thin numbers, under appropriate conditions; recall the relevant discussion in the Introduction. Theorem 11 proves convergence in total variation, Theorem 12 in entropy, and Theorem 14 in information divergence.

Recall that the total variation distance \( \|P - Q\| \) between two probability distributions \( P, Q \) on \( \mathbb{N}_0 \) is,
\[
\|P - Q\| := \sup_{B \subset \mathbb{N}_0} |P(B) - Q(B)| = \frac{1}{2} \sum_{k \geq 0} |P(k) - Q(k)|.
\]

**Theorem 11 (weak version):** For any distribution \( P \) on \( \mathbb{N}_0 \) with mean \( \lambda \),
\[
\|T_{1/n}(P^{*n}) - \text{Po}(\lambda)\| \to 0, \quad n \to \infty.
\]

**Proof:** In view of Scheffé’s lemma, pointwise convergence of discrete distributions is equivalent to convergence in total variation, so it suffices to show that, \( T_{1/n}(P^{*n})(z) \) converges to \( e^{-\lambda}z/\lambda z! \), for all \( z \geq 0 \).

Note that \( T_{1/n}(P^{*n}) = (T_{1/n}(P))^{*n} \), and that (2) implies the following elementary bounds for all \( \alpha \), using Jensen’s inequality:
\[
T_{\alpha}(P)(0) = \sum_{x=0}^{\infty} P(x)(1-\alpha)^x \geq (1-\alpha)^{\lambda}
\]
\[
T_{\alpha}(P)(1) = \sum_{x=1}^{\infty} P(x)x(1-\alpha)^{x-1}.
\]

Since for i.i.d. variables \( Y_i \), the probability \( \Pr\{Y_1 + \ldots + Y_n = z\} \geq \binom{n}{z} \Pr\{Y_1 = 1\}^z P\{Y_1 = 0\}^{n-z} \), taking \( \alpha = 1/n \) we obtain,
\[
(T_{1/n}(P))^{*n}(z) \geq \binom{n}{z} \left( \sum_{x=1}^{\infty} P(x) \frac{x}{n} \left( 1 - \frac{1}{n} \right)^{x-1} \right)^z \left( \left( 1 - \frac{1}{n} \right)^{\lambda} \right)^{n-z}
\]
\[
= \frac{n^z}{n^z z!} \sum_{x=1}^{\infty} P(x) x \left( 1 - \frac{1}{n} \right)^{x-1} \left( \left( 1 - \frac{1}{n} \right)^{\lambda} \right)^{n-z}.
\]

Now, for any fixed value of \( z \) and \( n \) tending to infinity,
\[
\frac{n^z}{n^z z!} \to \frac{1}{z!},
\]
and
\[
\left( 1 - \frac{1}{n} \right)^{(n-z)\lambda} \to e^{-\lambda},
\]
and by monotone convergence,
\[
\sum_{x=1}^{\infty} P(x) x \left( 1 - \frac{1}{n} \right)^{x-1} \to \lambda.
\]

Therefore,
\[
\lim inf_{n \to \infty} (T_{1/n}(P))^{*n}(z) \geq \text{Po}(\lambda, z).
\]

Since all \( (T_{1/n}(P))^{*n} \) are probability mass functions and so is \( \text{Po}(\lambda) \), the above \( \lim inf \) is necessarily a limit.
As usual, the entropy of a probability distribution $P$ on $\mathbb{N}_0$ is defined by,

$$H(P) = -\sum_{k \geq 0} P(k) \log P(k).$$

**Theorem 12 (thermodynamic version):** For any Poisson bounded distribution $P$ on $\mathbb{N}_0$ with mean $\lambda$,

$$H(T_{1/n}(P^n)) \to H(\text{Po}(\lambda)), \quad \text{as } n \to \infty.$$

**Proof:** The distribution $T_{1/n}(P^n)$ converges pointwise to the Poisson distribution so, by dominated convergence, it is sufficient to prove that $-T_{1/n}(P^n)(x) \log (T_{1/n}(P^n)(x))$ is dominated by a summable function. This easily follows from the simple bound in the following lemma.$\blacksquare$

**Lemma 13:** Suppose $P$ is Poisson bounded with ratio $\mu$. Then,

$$P(x) \leq \text{Po}(\mu, x) \cdot e^{\mu}, \quad \text{for all } x \geq 0.$$

**Proof:** Note that, for all $x$,

$$P(x) x^k \leq \sum_{x=0}^{\infty} P(x) x^k \leq \mu^k,$$

so that, in particular, $P(x) x^k \leq \mu^k$, and, $P(x) \leq \frac{\mu^x}{x!} = \text{Po}(\mu, x) e^{\mu}$. $\blacksquare$

According to [20, Proof of Theorem 2.5], $H(T_{1/n}(P^n)) \leq H(\text{Po}(\lambda))$ if $P$ is ultra log-concave, so for such distributions the theorem states that the entropy converges to its maximum. For ultra log-concave distributions the thermodynamic version also implies convergence in information divergence. This also holds for Poisson bounded distributions, which is easily proved using dominated convergence. As shown in the next theorem, convergence in information divergence can be established under quite general conditions.

**Theorem 14 (strong version):** For any distribution $P$ on $\mathbb{N}_0$ with mean $\lambda$ and $D(P||\text{Po}(\lambda)) < \infty$,

$$D(T_{1/n}(P^n)||\text{Po}(\lambda)) \to 0, \quad \text{as } n \to \infty.$$

The proof of Theorem 14 is given in the Appendix; it is based on a straightforward but somewhat technical application of the following general bound.

**Proposition 15:** Let $X$ be a random variable with distribution $P$ on $\mathbb{N}_0$ and with finite mean $\lambda/\alpha$, for some $\alpha \in (0, 1)$. If $D(P||\text{Po}(\lambda/\alpha)) < \infty$, then,

$$D(T_{\alpha}(P)||\text{Po}(\lambda)) \leq \frac{\alpha^2}{2(1-\alpha)} + E\left[\alpha X \log \left(\frac{\alpha X}{\lambda}\right)\right] < \infty. \quad (11)$$

**Proof:** First note that, since $P$ has finite mean, its entropy is bounded by the entropy of a geometric with the same mean, which is finite, so $H(P)$ is finite. Therefore, the divergence $D(P||\text{Po}(\lambda/\alpha))$ can be expanded as,

$$D(P||\text{Po}(\lambda)) = E\left[\log \left(\frac{P(X)}{\text{Po}(\lambda/\alpha, X)}\right)\right]$$

$$= E[\log(X!)] + \frac{\lambda}{\alpha} - H(P) - \frac{\lambda}{\alpha} \log \left(\frac{\lambda}{\alpha}\right).$$

$$\geq \frac{1}{2}E[\log^+ (2\pi X)] + E[X \log X] - H(P) - \frac{\lambda}{\alpha} \log \left(\frac{\lambda}{\alpha}\right), \quad (12)$$
where the last inequality follows from the Stirling bound,
\[
\log(x!) \geq \frac{1}{2} \log^+(2\pi x) + x \log x - x,
\]
and \(\log^+(x)\) denotes the function \(\log \max\{x, 1\}\). Since \(D(P||\text{Po}(\lambda)) < \infty\), (12) implies that \(E[X \log X]\) is finite. [Recall the convention that \(0 \log 0 = 0\).]

Also note that the representation of \(T_\alpha(P)\) in (2) can be written as,
\[
T_\alpha P(z) = \sum_{x=0}^\infty P(x) \Pr\{\text{Bin}(x, \alpha) = z\}.
\]
Using this and the joint convexity of information divergence in its two arguments (see, e.g., [6, Theorem 2.7.2]), the divergence of interest can be bounded as,
\[
D(T_\alpha(P)||\text{Po}(\lambda)) = D \left( \sum_{x=0}^\infty P(x) \text{Bin}(x, \alpha) \Bigg| \sum_{x=0}^\infty P(x) \text{Po}(\lambda) \right) \\
\leq \sum_{x=0}^\infty P(x) D(\text{Bin}(x, \alpha)||\text{Po}(\lambda)),
\]
(13)
where the first term (corresponding to \(x = 0\)) equals \(\lambda\). Since the Poisson measures form an exponential family, they satisfy a Pythagorean identity [8] which, together with the bound,
\[
D(\text{Bin}(x, p)||\text{Po}(xp)) \leq \frac{p^2}{2(1-p)},
\]
(14)
see, e.g., [18] or [24], gives, for each \(x \geq 1\),
\[
D(\text{Bin}(x, \alpha)||\text{Po}(\lambda)) = D(\text{Bin}(x, \alpha)||\text{Po}(\alpha x)) + D(\text{Po}(\alpha x)||\text{Po}(\lambda)) \\
\leq \frac{\alpha^2}{2(1-\alpha)} + \sum_{j=0}^\infty \text{Po}(\alpha x, j) \log \left( \frac{(\alpha x)^j \exp(-\alpha x)/j!}{\lambda^j \exp(-\lambda)/j!} \right) \\
= \frac{\alpha^2}{2(1-\alpha)} + \left( \alpha x \log \left( \frac{\alpha x}{\lambda} \right) - \alpha x + \lambda \right).
\]
Since the final bound clearly remains valid for \(x = 0\), substituting it into (13) gives (11). \(\blacksquare\)
IV. LAWS OF THIN NUMBERS: THE NON-I.I.D. CASE

In this section we state and prove more general versions of the law of thin numbers, for sequences of random variables that are not necessarily independent or identically distributed. Although some of the results in this section are strict generalizations of Theorems 11 and 14, their proofs are different.

We begin by showing that, using a general proof technique introduced in [24], the weak law of thin numbers can be established under weaker conditions than those in Theorem 11. The main idea is to use the data-processing inequality on the total variation distance between an appropriate pair of distributions.

Theorem 16 (weak version, non-i.i.d.): Let $P_1, P_2, \ldots$ be an arbitrary sequence of distributions on $\mathbb{N}_0$, and write $P^{(n)} = P_1 \ast P_2 \ast \cdots \ast P_n$ for the convolution of the first $n$ of them. Then,

$$\|T_{1/n}(P^{(n)}) - \text{Po}(\lambda)\| \to 0, \quad n \to \infty,$$

as long as the following three conditions are satisfied as $n \to \infty$:

(a) $a_n = \max_{1 \leq i \leq n} \left[1 - T_{1/n} P_i(0)\right] \to 0$;
(b) $b_n = \sum_{i=1}^{n} \left[1 - T_{1/n} P_i(0)\right] \to \lambda$;
(c) $c_n = \sum_{i=1}^{n} \left[1 - T_{1/n} P_i(0) - T_{1/n} P_i(1)\right] \to 0$.

Note that Theorem 16 can be viewed as a one-dimensional version of Grigelionis’ Theorem 1 in [14]; recall the relevant comments in the Introduction. Recently, Schuhmacher [30] established nonasymptotic, quantitative versions of this result, in terms of the Barbour-Brown distance, which metrizes weak convergence in the space of probability measures of point processes. As the information divergence is a finer functional than the Barbour-Brown distance, Schuhmacher’s results are not directly comparable with the finite-$n$ bounds we obtain in Propositions 15, 19 and Corollary 32.

Before giving the proof of the theorem, we state a simple lemma on a well-known bound for $\|\text{Po}(\lambda) - \text{Po}(\mu)\|$. Its short proof is included for completeness.

Lemma 17: For any $\lambda, \mu > 0$,

$$\|\text{Po}(\lambda) - \text{Po}(\mu)\| \leq 2 \left[1 - e^{-|\lambda - \mu|}\right] \leq 2|\lambda - \mu|.$$ 

Proof: Suppose, without loss of generality, that $\lambda > \mu$, and define two independent random variables $X \sim \text{Po}(\mu)$ and $Z \sim \text{Po}(\lambda - \mu)$, so that, $Y = X + Z \sim \text{Po}(\lambda)$. Then, by the coupling inequality [26],

$$\|\text{Po}(\lambda) - \text{Po}(\mu)\| \leq 2 \Pr\{X \neq Y\} = 2 \Pr\{Z \neq 0\} = 2\left[1 - e^{-(\lambda - \mu)}\right].$$

The second inequality in the lemma is trivial.

Proof of Theorem 16: First we introduce some convenient notation. Let $X_1, X_2, \ldots$ be independent random variables with $X_i \sim P_i$ for all $i$; for each $n \geq 1$, let $Y_1^{(n)}, Y_2^{(n)}, \ldots$ be independent random variables with $Y_i^{(n)} \sim T_{1/n} P_i$ for all $i$; and similarly let $Z_1^{(n)}, Z_2^{(n)}, \ldots$ be independent $\text{Po}(\lambda_i^{(n)})$ random variables, where $\lambda_i^{(n)} = T_{1/n} P_i(1)$, for $i, n \geq 1$. Also we define the sums, $S_n = \sum_{i=1}^{n} Y_i^{(n)}$ and $T_n = \sum_{i=1}^{n} Z_i^{(n)}$, and note that, $S_n \sim P^{(n)}$, and $T_n \sim \text{Po}(\lambda^{(n)})$, where $\lambda^{(n)} = \sum_{i=1}^{n} \lambda_i^{(n)}$, for all $n \geq 1$.

Note that $\lambda^{(n)} \to \lambda$ as $n \to \infty$, since,

$$\lambda^{(n)} = \sum_{i=1}^{n} \lambda_i^{(n)} = b_n - c_n,$$
and, by assumption, \( b_n \to \lambda \) and \( c_n \to 0 \), as \( n \to \infty \).

With these definitions in place, we approximate,
\[
\|T_{1/n}(P^{(n)}) - \Po(\lambda)\| \leq \|T_{1/n}(P^{(n)}) - \Po(\lambda^{(n)})\| + \|\Po(\lambda^{(n)}) - \Po(\lambda)\|,
\]
where, by Lemma 17, the second term is bounded by \( 2|\lambda^{(n)} - \lambda| \) which vanishes as \( n \to \infty \). Therefore, it suffices to show that the first term in (15) goes to zero. For that term,
\[
\|T_{1/n}(P^{(n)}) - \Po(\lambda^{(n)})\| = \|P_{S_n} - P_{T_n}\| \\
\leq \|P_{\{Y_i^{(n)}\}} - P_{\{Z_i^{(n)}\}}\| \\
\leq \sum_{i=1}^{n} \|T_{1/n} P_i - \Po(\lambda^{(n)}_i)\| \\
\leq \sum_{i=1}^{n} [\|T_{1/n} P_i - \Bern(\lambda^{(n)}_i)\| + \|\Bern(\lambda^{(n)}_i) - \Po(\lambda^{(n)}_i)\|],
\]
where the first inequality above follows from the fact that, being an \( f \)-divergence, the total variation distance satisfies the data-processing inequality [8]; the second inequality comes from the well-known bound on the total variation distance between two product measures as the sum of the distances between their respective marginals; and the third bound is simply the triangle inequality.

Finally, noting that, for any random variable \( X \sim P \), \( \|P - \Bern(P(1))\| = \Pr\{X \geq 2\} \), and also recalling the simple estimate,
\[
\|\Bern(p) - \Po(p)\| = p(1 - e^{-p}) \leq p^2,
\]
yields,
\[
\|T_{1/n}(P^{(n)}) - \Po(\lambda^{(n)})\| \leq c_n + \sum_{i=1}^{n} (\lambda^{(n)}_i)^2 \leq c_n + \lambda^{(n)} \max_{1 \leq i \leq n} \lambda^{(n)}_i \leq c_n + \lambda^{(n)} a_n,
\]
and, by assumption, this converges to zero as \( n \to \infty \), completing the proof.

Recall that, in the i.i.d. case, the weak law of thin numbers only required the first moment of \( P \) to be finite, while the strong version also required that the divergence from \( P \) to the Poisson distribution be finite. For a sum of independent, non-identically distributed random variables with finite second moments, Proposition 15 can be used as in the proof of Theorem 14 to prove the following result. Note that the precise conditions required are somewhat analogous to those in Theorem 16.

**Theorem 18 (strong version, non-i.i.d.):** Let \( P_1, P_2, \ldots \) be an arbitrary sequence of distributions on \( \mathbb{N}_0 \), where each \( P_i \) has finite mean \( \lambda_i \) and finite variance. Writing \( P^{(n)} \) for the convolution \( P_1 \ast P_2 \ast \cdots \ast P_n \), we have,
\[
D\left(T_{1/n}(P^{(n)})\Big\|\Po(\lambda)\right) \to 0, \quad n \to \infty,
\]
as long as the following two conditions are satisfied:
(a) \( \lambda^{(n)} = \frac{1}{n} \sum_{i=1}^{n} \lambda_i \to \lambda \), as \( n \to \infty \);
(b) \( \sum_{i=1}^{\infty} \frac{1}{i^2} E(X_i^2) < \infty \).

The proof of Theorem 18 is given in the Appendix, and it is based on Proposition 15. It turns out that under the additional condition of finite second moments, the proof of Proposition 15 can be refined to produce a stronger upper bound on the divergence.
Proposition 19: If \( P \) is a distribution on \( \mathbb{N}_0 \) with mean \( \lambda/\alpha \) and variance \( \sigma^2 < \infty \), for some \( \alpha \in (0, 1) \), then,

\[
D(T_\alpha(P) \| \text{Po}(\lambda)) \leq \alpha^2 \left( \frac{1}{2(1-\alpha)} + \frac{\sigma^2}{\lambda} \right). \tag{16}
\]

Proof: Recall that in the proof of Proposition 15 it was shown that,

\[
D(T_\alpha(P) \| \text{Po}(\lambda)) \leq \sum_{x=0}^\infty P(x)D(\text{Bin}(x, \alpha) \| \text{Po}(\lambda)), \tag{17}
\]

where,

\[
D(\text{Bin}(x, \alpha) \| \text{Po}(\lambda)) \leq \frac{\alpha^2}{2(1-\alpha)} + \lambda \left( \frac{\alpha x}{\lambda} \log \left( \frac{\alpha x}{\lambda} \right) - \frac{\alpha x}{\lambda} + 1 \right)
\leq \frac{\alpha^2}{2(1-\alpha)} + \lambda \left( \frac{\alpha x}{\lambda} - 1 \right)^2; \tag{18}\]

and where in the last step above we used the simple bound \( y \log y - y + 1 \leq y(y - 1) - y + 1 = (y - 1)^2 \), for \( y > 0 \). Substituting (18) into (17) yields,

\[
D(T_\alpha(P) \| \text{Po}(\lambda)) \leq \sum_{x=0}^\infty P(x) \left( \frac{\alpha^2}{2(1-\alpha)} + \lambda \left( \frac{\alpha x}{\lambda} - 1 \right)^2 \right)
= \frac{\alpha^2}{2(1-\alpha)} + \frac{\alpha^2}{\lambda} \sum_{x=0}^\infty P(x) \left( x - \frac{\lambda}{\alpha} \right)^2
= \frac{\alpha^2}{2(1-\alpha)} + \frac{\alpha^2 \sigma^2}{\lambda},
\]

as claimed. \( \blacksquare \)

Using the bound (16) instead of Proposition 15 the following more general version of the law of thin numbers can be established:

Theorem 20 (strong version, non-i.i.d.): Let \( \{X_i\} \) be a sequence of (not necessarily independent or identically distributed) random variables on \( \mathbb{N}_0 \), and write \( P^{(n)} \) for the distribution of the partial sum \( S_n = X_1 + X_2 + \cdots + X_n, \ n \geq 1 \). Assume that the \( \{X_i\} \) have finite means and variances, and that:

(a) They are “uniformly ultra bounded,” in that, \( \text{Var}(X_i) \leq CE(X_i) \) for all \( i \), with a common \( C < \infty \);
(b) Their means satisfy \( E(S_n) \to \infty \) as \( n \to \infty \);
(c) Their covariances satisfy,

\[
\lim_{n \to \infty} \frac{\sum_{1 \leq i < j \leq n} \text{Cov}(X_i, X_j)}{(E(S_n))^2} = 0.
\]

If in fact \( E(X_i) = \lambda > 0 \) for all \( i \), then,

\[
\lim_{n \to \infty} D(T_{1/n}(P^{(n)}) \| \text{Po}(\lambda)) = 0.
\]

More generally,

\[
\lim_{n \to \infty} D(T_{\alpha_n}(P^{(n)}) \| \text{Po}(\lambda)) = 0, \quad \text{where } \alpha_n = \lambda/E(S_n).
\]
Proof: Obviously it suffices to prove the general statement. Proposition \([19]\) applied to \(P^{(n)}\) gives,

\[
D(T_{\alpha_n}(P^{(n)})\|Po(\lambda)) \leq \alpha_n^2 \left( \frac{1}{2(1 - \alpha_n)} + \frac{\text{Var}(S_n)}{\lambda} \right)
\]

\[
= \frac{\alpha_n^2}{2(1 - \alpha_n)} + \frac{\lambda \text{Var}(S_n)}{(E(S_n))^2}
\]

\[
= \frac{\alpha_n^2}{2(1 - \alpha_n)} + \frac{\lambda}{(E(S_n))^2} \sum_{i=1}^{n} \text{Var}(X_i) + \frac{2\lambda}{(E(S_n))^2} \sum_{1 \leq i < j \leq n} \text{Cov}(X_i, X_j).
\]

The first and third terms tend to zero by assumptions (b) and (c), respectively. And using assumption (a), the second term is bounded above by,

\[
\frac{\lambda}{(E(S_n))^2} CE(S_n),
\]

which also tends to zero by assumption (b).
V. THE THINNING MARKOV CHAIN

Before examining the rate of convergence in the law of thin numbers, we consider a related and somewhat simpler problem for a Markov chain. Several of the results in this section may be of independent interest. The Markov chain we will discuss was first studied in [20, Proof of Theorem 2.5], and, within this context, it is a natural discrete analog of the Ornstein-Uhlenbeck process associated with the Gaussian distribution.

Definition 21: Let $P$ be a distribution on $\mathbb{N}_0$. For any $\alpha \in [0, 1]$ and $\lambda > 0$, we write $U_\alpha^\lambda(P)$ for the distribution,

$$U_\alpha^\lambda(P) = T_\alpha(P) \ast \text{Po}((1-\alpha)\lambda).$$

For simplicity, $U_\alpha^\lambda(P)$ is often written simply as $U_\alpha^\lambda P$.

We note that $U_\alpha^\lambda U_\beta^\lambda = U_{\alpha\beta}^\lambda$, and that, obviously, $U_\alpha^\lambda$ maps probability distributions to probability distributions. Therefore, if for a fixed $\lambda$ we define $Q^t = U_{e^{-t}}^\lambda$ for all $t \geq 0$, the collection $\{Q^t ; t \geq 0\}$ of linear operators on the space of probability measures on $\mathbb{N}_0$ defines a Markov transition semigroup. Specifically, for $i, j \in \mathbb{N}_0$, the transition probabilities,

$$Q^t_{ij} = (Q^t(\delta_i))(j) = (U_{e^{-t}}^\lambda(\delta_i))(j) = (T_{e^{-t}}(\delta_i) \ast \text{Po}((1-e^{-t})\lambda))(j) = \Pr\{\text{Bin}(i, e^{-t}) + \text{Po}((1-e^{-t})\lambda) = j\},$$

define a continuous-time Markov chain $\{Z_t ; t \geq 0\}$ on $\mathbb{N}_0$. It is intuitively clear that, as $\alpha \downarrow 0$ (or, equivalently, $t \to \infty$), the distribution $U_\alpha^\lambda P$ should converge to the $\text{Po}(\lambda)$ distribution. Indeed, the following two results state that $\{Z_t\}$ is ergodic, with unique invariant measure $\text{Po}(\lambda)$. Theorem [28] gives the rate at which it converges to $\text{Po}(\lambda)$.

Proposition 22: For any distribution $P$ on $\mathbb{N}_0$, $U_\alpha^\lambda (P)$ converges in total variation to $\text{Po}(\lambda)$, as $\alpha \downarrow 0$.

Proof: From the definition of $U_\alpha^\lambda (P)$,

$$
\|U_\alpha^\lambda(P) - \text{Po}(\lambda)\| = \|T_\alpha(P) \ast \text{Po}((1-\alpha)\lambda) - \text{Po}(\lambda)\|
\leq \|T_\alpha(P) - \text{Po}(\alpha\lambda)\| + \|(\text{Po}(\alpha\lambda) \ast \text{Po}((1-\alpha)\lambda) - \text{Po}(\lambda)\|
\leq 1/2 \|\text{Po}(\alpha\lambda)\| + \|T_\alpha(P) - \text{Po}(\alpha\lambda)\|
\leq 1/2 \|\text{Po}(\alpha\lambda)\| + \|T_\alpha(P) - \text{Po}(\alpha\lambda)\| + 1/2 \sum_{x=1}^\infty |T_\alpha(P)(x) - \text{Po}(\alpha\lambda, x)|
\leq 1/2 \|\text{Po}(\alpha\lambda)\| + \|T_\alpha(P) - \text{Po}(\alpha\lambda)\| + 1/2 \sum_{x=1}^\infty (T_\alpha(P)(x) + \text{Po}(\alpha\lambda, x))
\leq 2 - T_\alpha(P)(0) - \text{Po}(\alpha\lambda, 0),
$$

where (19) follows from the fact that convolution with any distribution is a contraction with respect to the $L^1$ norm, (20) follows from the triangle inequality, and (21) converges to zero because of the bound (10).

Using this, we can give a characterization of the Poisson distribution.

Corollary 23: Let $P$ denote a discrete distribution with mean $\lambda$. If $P = U_\alpha^\lambda(P)$ for some $\alpha \in (0, 1)$, then $P = \text{Po}(\lambda)$. That is, $\text{Po}(\lambda)$ is the unique invariant measure of the Markov chain $\{Z_t\}$, and, moreover,

$$D(U_\alpha^\lambda(P)\|\text{Po}(\lambda)) \to 0, \quad \text{as } \alpha \downarrow 0,$$
if and only if \( D(U^\lambda_\alpha(P)\|\text{Po}(\lambda)) < \infty \) for some \( \alpha > 0 \).

**Proof:** Assume that \( P = U^\lambda_\alpha(P) \). Then for any \( n, P = U^\lambda_\alpha^n(P) \), so for any \( \epsilon > 0 \), by Proposition \[ \|P - \text{Po}(\lambda)\| = \|U^\lambda_\alpha(P) - \text{Po}(\lambda)\| \leq \epsilon \] for \( n \) sufficiently large. The strengthened convergence of \( D(U^\lambda_\alpha(P)\|\text{Po}(\lambda)) \) to zero if \( D(U^\lambda_\alpha(P)\|\text{Po}(\lambda)) < \infty \) can be proved using standard arguments along the lines of the corresponding discrete-time results in \[12\][3][16]. \[ \square \]

Next we shall study the rate of convergence of \( U^\lambda_\alpha(P) \) to the Poisson distribution. It is easy to check that the Markov chain \( \{Z_t\} \) is in fact **reversible** with respect to its invariant measure \( \text{Po}(\lambda) \). Therefore, the natural setting for the study of its convergence is the \( L^2 \) space of functions \( f : \mathbb{N}_0 \to \mathbb{R} \) such that, \( E[f(Z)^2] < \infty \) for \( Z \sim \text{Po}(\lambda) \). This space is also endowed with the usual inner product, \( \langle f, g \rangle = E[f(Z)g(Z)] \), for \( Z \sim \text{Po}(\lambda), f, g \in L^2 \), and the linear operators \( U^\lambda_\alpha \) act on functions \( f \in L^2 \) by mapping each \( f \) into, \( (U^\lambda_\alpha f)(x) = E[f(Z_{\alpha,\lambda,x})] \) for \( Z_{\alpha,\lambda,x} \sim U^\lambda_\alpha(\delta_x) \).

In other words, \( (U^\lambda_\alpha f)(x) = E[Z_{\log(1/\alpha)}|Z_0 = x], \ x \in \mathbb{N}_0. \) The reversibility of \( \{Z_t\} \) with respect to \( \text{Po}(\lambda) \) implies that \( U^\lambda_\alpha \) is a self-adjoint linear operator on \( L^2 \), therefore, its eigenvectors are orthogonal functions. In this context, we introduce the Poisson-Charlier family of orthogonal polynomials \( P^\lambda_k : \)

**Definition 24:** For given \( \lambda \), the Poisson-Charlier polynomial of order \( k \) is given by, 
\[
P^\lambda_k(x) = \frac{1}{(\lambda^k k!)^{1/2}} \sum_{\ell=0}^{k} (-\lambda)^{k-\ell} \left( \begin{array}{c} k \\ \ell \end{array} \right) x^\ell.
\]

Some well-known properties of the Poisson-Charlier polynomials are listed in the following lemma without proof. Note that their exact form depends on the chosen normalization; other authors present similar results, but with different normalizations.

**Lemma 25:** For any \( \lambda, \mu, k \) and \( \ell \):

1) \( \langle P^\lambda_k, P^\lambda_\ell \rangle = \delta_{k\ell} \) \hspace{1cm} (22)
2) \( P^\lambda_{k+1}(x) = \frac{xP^\lambda_k(x-1) - \lambda P^\lambda_k(x)}{(\lambda(k+1))^{1/2}} \) \hspace{1cm} (23)
3) \( P^\lambda_k(x+1) - P^\lambda_k(x) = \left( \frac{k}{\lambda} \right)^{1/2} P^\lambda_{k-1}(x) \) \hspace{1cm} (24)
4) \( P^{\lambda+\mu}(x+y) = \sum_{\ell=0}^{k} \left( \begin{array}{c} k \\ \ell \end{array} \right) \alpha^\ell (1 - \alpha)^{k-\ell} \right)^{1/2} P^\lambda_\ell(x)P^\mu_{k-\ell}(y), \) \hspace{1cm} (25)

where \( \alpha = \lambda/\lambda(\lambda + \mu). \) \hspace{1cm} (26)

Observe that, since the Poisson-Charlier polynomials form an orthonormal set, any function \( f \in L^2 \) can be expanded as, 
\[
f(x) = \sum_{k=0}^{\infty} \langle f, P^\lambda_k \rangle P^\lambda_k(x).
\]
It will be convenient to be able to translate between factorial moments and the “Poisson-Charlier moments,” $E \left[ P^\lambda_k(X) \right]$. For example, if $X \sim \text{Po}(\lambda)$, then taking $\ell = 0$ in (22) shows that $E[P^\lambda_k(X)] = 0$ for all $k \geq 1$. More generally, the following proposition shows that the role of the Poisson-Charlier moments with respect to the Markov chain $\{Z_t\}$ is analogous to the role played by the factorial moments with respect to the pure thinning operation; cf. Lemma 3. Its proof, given in the Appendix, is similar to that of Lemma 3.

**Proposition 26:** Let $X \sim P$ be a random variable with mean $\lambda$ and write $X_{\alpha,\lambda}$ for a random variable with distribution $U^\lambda_{\alpha}(P)$. Then,

$$E \left[ P^\lambda_k(X_{\alpha,\lambda}) \right] = \alpha^k E \left[ P^\lambda_k(X) \right].$$

If we replace $\alpha$ by $\exp(-t)$ and assume that the thinning Markov chain $\{Z_t\}$ has initial distribution $Z_0 \sim P$ with mean $\lambda$, then, Proposition 26 states that,

$$E[P^\lambda_k(Z_t)] = e^{-kt} E[P^\lambda_k(Z_0)],$$

that is, the Poisson-Charlier moments of $Z_t$ tend to 0 like $\exp(-kt) E \left[ P^\lambda_k(Z_0) \right]$. Similarly, expanding any $f \in L^2$ in terms of Poisson-Charlier polynomials, $f(x) = \sum_{k=0}^{\infty} \langle f, P^\lambda_k \rangle P^\lambda_k(x)$, and using Proposition 26,

$$E[f(Z_t)] = E \left[ \sum_{k=0}^{\infty} \langle f, P^\lambda_k \rangle P^\lambda_k(Z_t) \right] = \sum_{k=0}^{\infty} \exp(-kt) \langle f, P^\lambda_k \rangle E \left[ P^\lambda_k(X) \right].$$

Thus, the rate of convergence of $\{Z_t\}$ will be dominated by the term corresponding to $E \left[ P^\lambda_k(X) \right]$, where $\kappa$ is the first $k \geq 1$ such that $E \left[ P^\lambda_k(X) \right] \neq 0$.

The following proposition (proved in the Appendix) will be used in the proof of Theorem 28 below, which shows that this is indeed the right rate in terms of the $\chi^2$ distance. Note that there is no restriction on the mean of $X \sim P$ in the proposition.

**Proposition 27:** If $X \sim P$ is Poisson bounded, then the the likelihood ratio $P/P\text{Po}(\lambda)$ can be expanded as:

$$\frac{P(x)}{\text{Po}(\lambda, x)} = \sum_{k=0}^{\infty} E[\alpha^k P^\lambda_k(X)] P^\lambda_k(x), \quad x \geq 0.$$

Assuming $X \sim P \in PB(\lambda)$, combining Propositions 26 and 27, we obtain that,

$$\frac{U^\lambda_{\alpha} P(x)}{\text{Po}(\lambda, x)} = \sum_{k=0}^{\infty} E \left[ P^\lambda_k(X_{\alpha,\lambda}) \right] P^\lambda_k(x) = 1 + \sum_{k=\kappa}^{\infty} \alpha^k E \left[ P^\lambda_k(X) \right] P^\lambda_k(x) = 1 + \alpha^\kappa \sum_{k=\kappa}^{\infty} \alpha^{k-\kappa} E \left[ P^\lambda_k(X) \right] P^\lambda_k(x)$$(28)

where, as before, $\kappa$ denotes the first integer $k \geq 1$ such that $E \left[ P^\lambda_k(X) \right] \neq 0$. This sum can be viewed as a discrete analog of the well-known Edgeworth expansion for the distribution of a continuous random variable. A technical disadvantage of both this and the standard Edgeworth expansion is that, although the sum converges in $L^2$, truncating it to a finite number of terms in general produces an expression which
may take negative values. By a more detailed analysis we shall see in the following two sections how to get around this problem.

For now, we determine the rate of convergence of $U_\alpha^\lambda P$ to $\text{Po}(\lambda)$ in terms of the $\chi^2$ distance between $U_\alpha^\lambda P$ and $\text{Po}(\lambda)$; recall the definition of the $\chi^2$ distance between two probability distributions $P$ and $Q$ on $\mathbb{N}_0$:

$$\chi^2(P, Q) = \sum_{x=0}^{\infty} Q(x) \left( \frac{P(x)}{Q(x)} - 1 \right)^2.$$

**Theorem 28:** If $X \sim P$ is Poisson bounded, then $\chi^2(U_\alpha^\lambda P, \text{Po}(\lambda))$ is finite for all $\alpha \in [0, 1]$ and,

$$\frac{\chi^2(U_\alpha^\lambda P, \text{Po}(\lambda))}{\alpha^{2\kappa}} \to E\left[P_\kappa^\lambda(X)\right]^2,$$

as $\alpha \downarrow 0$,

where $\kappa$ denotes the smallest $k > 0$ such that $E\left[P_\kappa^\lambda(X)\right] \neq 0$.

**Proof:** The proof is based on a Hilbert space argument using the fact that the Poisson-Charlier polynomials are orthogonal. Suppose $X \sim P \in PB(\mu)$. Using Proposition 27,

$$\chi^2(U_\alpha^\lambda P, \text{Po}(\lambda)) = \sum_{x=0}^{\infty} \text{Po}(\lambda, x) \left( \frac{U_\alpha^\lambda P(x)}{\text{Po}(\lambda, x)} - 1 \right)^2$$

$$= \sum_{x=0}^{\infty} \text{Po}(\lambda, x) \left( \sum_{k=\kappa}^{\infty} \alpha^k E[P_k^\lambda(X)] P_k^\lambda(x) \right)^2$$

$$= \sum_{k=\kappa}^{\infty} \alpha^{2k} E[P_k^\lambda(X)]^2,$$

where the last step follows from the orthogonality relation (22). For $\alpha = 1$ we have,

$$\chi^2(P, \text{Po}(\lambda)) = \sum_{x=0}^{\infty} \text{Po}(\lambda, x) \left( \frac{P(x)}{\text{Po}(\lambda, x)} - 1 \right)^2$$

$$= \sum_{x=0}^{\infty} \text{Po}(\lambda, x) \left( \frac{P(x)}{\text{Po}(\lambda, x)} \right)^2 - 1,$$

which is finite. From the previous expansion we see that $\chi^2(U_\alpha^\lambda P, \text{Po}(\lambda))$ is increasing in $\alpha$, which implies the finiteness claim. Moreover, that expansion has $\alpha^{2\kappa} E[P_\kappa^\lambda(X)]^2$ as its dominant term, implying the stated limit.

Theorem 28 readily leads to upper bounds on the rate of convergence in terms of information divergence via the standard bound,

$$D(P\|Q) \leq \log(1 + \chi^2(P, Q)) \leq \chi^2(P, Q),$$

which follows from direct applications of Jensen’s inequality. Furthermore, replacing this bound by the well-known approximation [8],

$$D(P\|Q) \approx \frac{1}{2} \chi^2(P, Q),$$

gives the estimate,

$$D(U_\alpha^\lambda P\|\text{Po}(\lambda)) \approx \alpha^{2\kappa} \frac{E\left[P_\kappa^\lambda(X)\right]^2}{2} = \frac{E\left[P_\kappa^\lambda(U_\alpha X)\right]^2}{2}.$$

We shall later prove that, in certain cases, this approximation can indeed be rigorously justified.
VI. THE RATE OF CONVERGENCE IN THE STRONG LAW OF THIN NUMBERS

Let $X \sim P$ be a random variable on $\mathbb{N}_0$ with mean $\lambda$. In Theorem 14 we showed that, if $D(P\|\text{Po}(\lambda))$ is finite, then,

$$D(T_{1/n}(P^{*n})\|\text{Po}(\lambda)) \to 0, \quad \text{as } n \to \infty. \quad (29)$$

If $P$ also has finite variance $\sigma^2$, then Proposition 19 implies that, for all $n \geq 2$,

$$D \left( T_{1/n} (P^{*n}) \| \text{Po} (\lambda) \right) \leq \frac{\sigma^2}{n\lambda} + \frac{1}{n^2}, \quad (30)$$

suggesting a convergence rate of order $1/n$. In this section, we prove more precise upper bounds on the rate of convergence in the strong law of thin numbers (29). For example, if $X$ is an ultra bounded random variable with $\sigma^2 \neq \lambda$, then we show that in fact,

$$\limsup_{n \to \infty} n^2 D \left( T_{1/n}(P^{*n}) \| \text{Po}(\lambda) \right) \leq 2c^2,$$

where $c = \mathbb{E} [P_2(X)] = (\sigma^2 - \lambda)/(\lambda \sqrt{2}) \neq 0$. This follows from the more general result of Corollary 32; its proof is based on a detailed analysis of the scaled Fisher information introduced in in [24]. We begin by briefly reviewing some properties of the scaled Fisher information:

**Definition 29:** The scaled Fisher information of a random variable $X \sim P$ with mean $\lambda$, is defined by,

$$K(X) = K(P) = \lambda \mathbb{E} \left[ \rho_X (X)^2 \right]$$

where $\rho_X$ denotes the scaled score function,

$$\rho_X (x) = \frac{(x + 1) P(x + 1)}{\lambda P(x)} - 1.$$

In [24, Proposition 2] it was shown, using a logarithmic Sobolev inequality of Bobkov and Ledoux [41], that for any $X \sim P$,

$$D (P\|\text{Po}(\lambda)) \leq K(X), \quad (31)$$

under mild conditions on the support of $P$. Also, [24, Proposition 3] states that $K(X)$ satisfies a subadditivity property: For independent random variables $X_1, X_2, \ldots, X_n$,

$$K \left( \sum_{i=1}^n X_i \right) \leq \sum_{i=1}^n \frac{\mathbb{E}[X_i]}{\lambda} K(X_i) \quad (32)$$

where $\lambda = \sum_i \mathbb{E}(X_i)$. In particular, recalling that the thinning of a convolution is the convolution of the corresponding thinnings, if $X_1, X_2, \ldots, X_n$ are i.i.d. random variables with mean $\lambda$ then the bounds in (31) and (32) imply,

$$D \left( T_{1/n}(P^{*n}) \| \text{Po} (\lambda) \right) \leq K \left( T_{1/n}(P) \right). \quad (33)$$

Therefore, our next goal is to determine the rate at which $K(T_\alpha(X))$ tends to 0 for $\alpha$ tending to 0. We begin with the following proposition; its proof is given in Appendix.
**Proposition 30:** If $X \sim P$ is Poisson bounded, then $P$ admits the representation,

$$P(x) = \frac{1}{x!} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{E[X^{x+\ell}]}{\ell!}.$$ 

Moreover, the truncated sum from $\ell = 0$ to $m$ is an upper bound for $P(x)$ if $m$ is even, and a lower bound if $m$ is odd.

An important consequence of this proposition is that $T_\alpha P(x)$ tends to zero like $\alpha^x$, as $\alpha \downarrow 0$. Moreover, it leads to the following asymptotic result for the scaled Fisher information, also proved in the Appendix.

**Theorem 31:** Suppose $X \sim P$ has mean $\lambda$ and it is ultra bounded with ratio $\lambda$. Let $\kappa$ denote the smallest integer $k \geq 1$ such that $E[P_\lambda^k(X)] \neq 0$. Then,

$$\lim_{\alpha \to 0} \frac{K(T_\alpha P)}{\alpha^\kappa} = \kappa c^2,$$

where $c = E[P_\kappa^\lambda(X)]$.

Combining Theorem 31 with (33) immediately yields:

**Corollary 32:** Suppose $X \sim P$ has mean $\lambda$ and it is ultra bounded with ratio $\lambda$. Let $\kappa$ denote the smallest integer $k \geq 1$ such that $E[P_\lambda^k(X)] \neq 0$. Then,

$$\limsup_{n \to \infty} n^\kappa D\left(T_{1/n} (P^n) \parallel \text{Po} (\lambda) \right) \leq \kappa c^2,$$

where $c = E[P_\kappa^\lambda(X)]$. 
VII. Monotonicity Results for the Scaled Fisher Information

In this section we establish a finer result for the behavior of the scaled Fisher information upon thinning, and use that to deduce a stronger finite-\(n\) upper bound for the strong law of thin numbers. Specifically, if \(X \sim P\) is ULC with mean \(\lambda\), and \(X_\alpha\) denotes a random variable with distribution \(T_\alpha P\), we will show that \(K(X_\alpha) \leq \alpha^2 K(X)\). This implies that, for all ULC random variables \(X\), we have the following finite-\(n\) version of the strong law of thin numbers,

\[ D(T_{1/n}(P^n)||\text{Po}(\lambda)) \leq \frac{K(X)}{n^2}. \]

Note that, unlike the more general result in (30) which gives a bound of order \(1/n\), the above bound is of order \(1/n^2\), as long as \(X\) is ULC.

The key observation for these results is in the following lemma.

Lemma 33: Suppose \(X\) is a ULC random variable with distribution \(P\) and mean \(\lambda\). For any \(\alpha \in (0, 1)\), write \(X_\alpha\) for a random variable with distribution \(T_\alpha P\). Then the derivative of \(K(X_\alpha)/\alpha\) with respect to \(\alpha\) satisfies,

\[ \frac{\partial}{\partial \alpha} \left( \frac{K(X_\alpha)}{\alpha} \right) = \frac{1}{\alpha^2} S(X_\alpha), \]

where, for a random variable \(Y\) with mass function \(Q\) and mean \(\mu\), we define,

\[ S(Y) = \sum_{y=0}^{\infty} \frac{Q(y+1)(y+1)}{\mu Q(y)} \left( \frac{Q(y+1)(y+1)}{Q(y)} - \frac{Q(y+2)(y+2)}{Q(y+1)} \right)^2. \]

Proof: This result follows on using the expression for the derivative of \(T_\alpha P\) arising as the case \(f(\alpha) = g(\alpha) = 0\) in Proposition 3.6 of [20], that is,

\[ \frac{\partial}{\partial \alpha} (T_\alpha P)(x) = \frac{1}{\alpha} \left[ x(T_\alpha P)(x) - (x+1)(T_\alpha P)(x) \right]. \]

Using this, for each \(x\) we deduce that,

\[
\begin{align*}
\frac{\partial}{\partial \alpha} \left( \frac{(T_\alpha P)(x+1)^2(x+1)^2}{\alpha^2(T_\alpha P)(x)\lambda} \right) &= \frac{(T_\alpha P)(x+1)(x+1)}{\alpha^2 \lambda} \left( \frac{(T_\alpha P)(x+1)(x+1)}{(T_\alpha P)(x)} - \frac{(T_\alpha P)(x+2)(x+2)}{(T_\alpha P)(x+1)} \right)^2 \\
&\quad + \frac{1}{\alpha^3 \lambda} \left( \frac{(T_\alpha P)(x+1)^2(x+1)^2}{(T_\alpha P)(x)} - \frac{(T_\alpha P)(x+2)^2(x+2)^2(x+1)}{(T_\alpha P)(x+1)} \right).
\end{align*}
\]

The result follows (with the term-by-term differentiation of the infinite sum justified) if the sum of these terms in \(x\) is absolutely convergent. The first terms are positive, and their sum is absolutely convergent to \(S\) by assumption. The second terms form a collapsing sum, which is absolutely convergent assuming that,

\[ \sum_{x=0}^{\infty} \frac{(T_\alpha P)(x+1)^2(x+1)^2 x}{(T_\alpha P)(x)} < \infty. \]

Note that, for any ULC distribution \(Q\), by definition we have for all \(x\), \((x+1)Q(x+1)/Q(x) \leq xQ(x)/Q(x-1)\), so that the above sum is bounded above by,

\[ \frac{(T_\alpha P)(1)}{(T_\alpha P)(0)} \sum_x (T_\alpha P)(x+1)(x+1)x, \]
which is finite by Proposition 9.

We now deduce the following theorem, which parallels Theorem 8 respectively of [35], where a corresponding result is proved for the information divergence.

**Theorem 34:** Let $X \sim P$ be a ULC random variable with mean $\lambda$. Write $X_\alpha$ for a random variable with distribution $T_\alpha P$. Then:

\begin{align*}
(i) & \quad K(X_\alpha) \leq \alpha^2 K(X), \quad \alpha \in (0, 1); \\
(ii) & \quad D(T_{1/n}(P^n) \parallel P_0(\lambda)) \leq \frac{K(X)}{n^2}, \quad n \geq 2.
\end{align*}

**Proof:** The first part follows from the observation that $K(T_\alpha X) / \alpha^2$ is increasing in $\alpha$, since, by Lemma 33 its derivative is $(S(T_\alpha X) - K(T_\alpha X)) / \alpha^3$. Taking $g(y) = P(y + 1)(y + 1)/P(y)$ in the more technical Lemma 35 below, we deduce that $S(Y) \geq K(Y)$ for any random variable $Y$, and this proves $(i)$. Then $(ii)$ immediately follows from $(i)$ combined with the earlier bound (33), upon recalling that thinning preserves the ULC property [20].

Consider the finite difference operator $\Delta$ defined by, $(\Delta g)(x) = g(x + 1) - g(x)$, for functions $g : \mathbb{N}_0 \to \mathbb{R}$. We require a result suggested by relevant results in [5][23]. Its proof is given in the Appendix.

**Lemma 35:** Let $Y$ be ULC random variable with distribution $P$ on $\mathbb{N}_0$. Then for any function $g$, defining $\mu = \sum_y P(y)g(y)$,

$$
\sum_{y=0}^{\infty} P(y)(g(y) - \mu)^2 \leq \sum_{y=0}^{\infty} P(y + 1)(y + 1)\Delta g(y)^2.
$$
VIII. BOUNDS IN TOTAL VARIATION

In this section, we show that a modified version of the argument used in the proof of Proposition 19 gives an upper bound to the rate of convergence in the weak law of small numbers. If $X \sim P$ has mean $\lambda$ and variance $\sigma^2$, then combining the bound (16) of Proposition 19 with Pinsker’s inequality we obtain,

$$\|T_1/n(P^\ast n) - Po(\lambda)\| \leq \left( \frac{1}{2n^2(1-n^{-1})} + \frac{\sigma^2}{n\lambda} \right)^{1/2},$$

which gives an upper bound of order $n^{-1/2}$. From the asymptotic upper bound on information divergence, Corollary 32, we know that one should be able to obtain upper bounds of order $n^{-1}$. Here we derive an upper bound on total variation using the same technique used in the proof of Proposition 19.

**Theorem 36:** Let $P$ be a distribution on $\mathbb{N}_0$ with finite mean $\lambda$ and variance $\sigma^2$. Then,

$$\|T_1/n(P^\ast n) - Po(\lambda)\| \leq \frac{1}{n2^{1/2}} + \frac{\sigma}{n^{1/2}} \min\{1, \frac{1}{2\lambda^{1/2}}\},$$

for all $n \geq 2$.

The proof uses the following simple bound, which follows easily from a result of Yannaros, [34, Theorem 2.3]; the details are omitted.

**Lemma 37:** For any $\lambda > 0$, $m \geq 1$ and $t \in (0, 1/2]$, we have,

$$\|\text{Bin}(m, t) - Po(\lambda)\| \leq t2^{-1/2} + |mt - \lambda| \min\{1, \frac{1}{2\lambda^{1/2}}\}.$$

**Proof:** The first inequality in the proof of Proposition 19 remains valid due to the convexity of the total variation norm (since it is an $f$-divergence). The next equality becomes an inequality, and it is justified by the triangle, and we have:

$$\|T_1/n(P^\ast n) - Po(\lambda)\| = \frac{1}{2} \sum_{x \geq 0} \left| \sum_{y \geq 0} P^\ast n(y) \left[ \Pr\{\text{Bin}(y, 1/n) = x\} - Po(\lambda, x) \right] \right|$$

$$\leq \sum_{y \geq 0} P^\ast n(y) \frac{1}{2} \sum_{x} |\Pr\{\text{Bin}(y, 1/n) = x\} - Po(\lambda, x)|$$

$$= \sum_{y \geq 0} P^\ast n(y) \|\text{Bin}(y, 1/n) - Po(\lambda)\|.$$

And using Lemma 37 leads to,

$$\|T_1/n(P^\ast n) - Po(\lambda)\| \leq \sum_{y \geq 0} P^\ast n(y) \|\text{Bin}(y, 1/n) - Po(\lambda)\|.$$

$$= \sum_{y \geq 0} P^\ast n(y) \left( \frac{1}{n2^{1/2}} + \frac{1}{n} \left| \frac{y}{n} - \lambda \right| \min\{1, \frac{1}{2\lambda^{1/2}}\} \right),$$

and the result follows by an application of Hölder’s inequality.
IX. Compound Thinning

There is a natural generalization of the thinning operation, via a process which closely parallels the generalization of the Poisson distribution to the compound Poisson. Starting with a random variable \( Y \sim P \) with values in \( \mathbb{N}_0 \), the \( \alpha \)-thinned version of \( Y \) is obtained by writing \( Y = 1 + 1 + \cdots + 1 \) (\( Y \) times), and then keeping each of these 1s with probability \( \alpha \), independently of all the others; cf. (I) above.

More generally, we choose and fix a “compounding” distribution \( Q \) on \( \mathbb{N} = \{1, 2, \ldots \} \). Given \( Y \sim P \) on \( \mathbb{N}_0 \) and \( \alpha \in [0, 1] \), then the compound \( \alpha \)-thinned version of \( Y \) with respect to \( Q \), or, for short, the \((\alpha, Q)\)-thinned version of \( Y \), is the random variable which results from first thinning \( Y \) as above and then replacing of the 1s that are kept by an independent random sample from \( Q \),

\[
\sum_{n=1}^{Y} B_n \xi_n, \quad B_i \sim \text{i.i.d.} \text{ Bern}(\alpha), \quad \xi_i \sim \text{i.i.d.} \text{ } Q,
\]

where all the random variables involved are independent. For fixed \( \alpha \) and \( Q \), we write \( T_{\alpha, Q}(P) \) for the distribution of the \((\alpha, Q)\)-thinned version of \( Y \sim P \). Then \( T_{\alpha, Q}(P) \) can be expressed as a mixture of “compound binomials” in the same way as \( T_{\alpha}(P) \) is a mixture of binomials. The compound binomial distribution with parameters \( n, \alpha, Q \), denoted \( \text{CBin}(n, \alpha, Q) \), is the distribution of the sum of \( n \) i.i.d. random variables, each of which is the product of a Bernoulli random variable and an independent \( \xi \sim Q \) random variable. In other words, it is the \((\alpha, Q)\)-thinned version of the point mass at \( n \), i.e., the distribution of \((37)\) with \( Y = n \) w.p.1. Then we can express the probabilities of the \((\alpha, Q)\)-thinned version of \( P \) as,

\[
T_{\alpha, Q}(P)(k) = \sum_{\ell \geq k} P(\ell) \Pr\{\text{CBin}(\ell, \alpha, Q) = k\}.
\]

The following two observations are immediate from the definitions.

1) Compound thinning maps a Bernoulli sum into a compound Bernoulli sum: If \( P \) is the distribution of the Bernoulli sum \( \sum_{i=1}^{n} B_i \) where the \( B_i \) are independent \( \text{Bern}(p_i) \), then \( T_{\alpha, Q}(P) \) is the distribution of the “compound Bernoulli sum,” \( \sum_{i=1}^{n} B'_i \xi_i \) where the \( B'_i \) are independent \( \text{Bern}(\alpha p_i) \), and the \( \xi_i \) are i.i.d. with distribution \( Q \), independent of the \( B_i \).

2) Compound thinning maps the Poisson to the compound Poisson distribution, that is, \( T_{\alpha, Q}(\text{Po}(\lambda)) = \text{CPo}(\alpha \lambda, Q) \), the compound Poisson distribution with rate \( \alpha \lambda \) and compounding distribution \( Q \). Recall that \( \text{CPo}(\lambda, Q) \) is defined as the distribution of,

\[
\sum_{i=1}^{\Pi_{\lambda}} \xi_i,
\]

where the \( \xi_i \) are as before, and \( \Pi_{\lambda} \) is a \( \text{Po}(\lambda) \) random variable that is independent of the \( \xi_i \).

Perhaps the most natural way in which the compound Poisson distribution arises is as the limit of compound binomials. That is, \( \text{CBin}(n, \lambda/n, Q) \rightarrow \text{CPo}(\lambda, Q) \), as \( n \rightarrow \infty \), or, equivalently,

\[
T_{1/n, Q}(\text{Bin}(n, \lambda)) = T_{1/n, Q}(P^{*n}) \rightarrow \text{CPo}(\lambda, Q),
\]

where \( P \) denotes the \( \text{Bern}(\lambda) \) distribution.

As with the strong law of thin numbers, this results remains true for general distributions \( P \), and the convergence can be established in the sense of information divergence:

**Theorem 38:** Let \( P \) be a distribution on \( \mathbb{N}_0 \) with mean \( \lambda > 0 \) and finite variance \( \sigma^2 \). Then, for any probability measure \( Q \) on \( \mathbb{N} \),

\[
D(T_{1/n, Q}(P^{*n})\|\text{CPo}(\lambda, Q)) \rightarrow 0, \quad \text{as } n \rightarrow \infty,
\]
as long as $D(P\|\text{Po}(\lambda)) < \infty$.

The proof is very similar to that of Theorem 14 and thus omitted. In fact, the same argument as that proof works for non-integer-valued compounding. That is, if $Q$ is an arbitrary probability measure on $\mathbb{R}^d$, then compound thinning a $\mathbb{N}_0$-valued random variable $Y \sim P$ as in (37) gives a probability measure $T_{\alpha,Q}(P)$ on $\mathbb{R}^d$.

It is somewhat remarkable that the statement and proof of most of our results concerning the information divergence remain essentially unchanged in this case. For example, we easily obtain the following analog of Proposition 19.

**Proposition 39**: If $P$ is a distribution on $\mathbb{N}_0$ with mean $\lambda/\alpha$ and variance $\sigma^2 < \infty$, for some $\alpha \in (0, 1)$, then, for any probability measure $Q$ on $\mathbb{R}^d$,

$$D(T_{\alpha,Q}(P)\|\text{CPo}(\lambda, Q)) \leq \alpha^2 \left( \frac{1}{2(1 - \alpha)} + \frac{\sigma^2}{\lambda} \right).$$

The details of the argument of the proof of the proposition are straightforward extensions of the corresponding proof of Proposition 19.
ACKNOWLEDGEMENT

The authors wish to thank Emre Telatar and Christophe Vignat for hosting a small workshop in January 2006, during which some of these ideas developed. Jan Swart also provided us with useful comments.

APPENDIX

Proof of Lemma 3: Simply apply Lemma 4 to Definition 1 with $Y \sim P$, to obtain,

$$E[Y^k] = E\left[\left(\sum_{x=1}^Y B_x\right)^k\right]$$

$$= E\left\{E\left[\left(\sum_{x=1}^Y B_x\right)^k \mid Y\right]\right\}$$

$$= E\left\{E\left[\sum_{k_x \in \{0,1\}} \sum_{k_x=k} k! \prod_{x=1}^Y B_x^{k_x} \mid Y\right]\right\}$$

$$= E\left[\left(\frac{Y}{k}\right) k! \alpha^k\right]$$

$$= \alpha^k E[Y^k],$$

using the fact that the sequence of factorial moments of the Bern($\alpha$) distribution are \{1, $\alpha$, 0, 0, ...\}. □

Proof of Proposition 5: Assume that $T_{\alpha_0} P = T_{\alpha_0} Q$ for a given $\alpha_0 > 0$. Then, recalling the property stated in (6), it follows that, $T_{\alpha} P = T_{\alpha} Q$ for all $\alpha \in [0, \alpha_0]$. In particular, $T_{\alpha} P(0) = T_{\alpha} Q(0)$ for all $\alpha \in [0, \alpha_0]$, i.e.,

$$\sum_{x=0}^{\infty} P(x)(1-\alpha)^x = \sum_{x=0}^{\infty} Q(x)(1-\alpha)^x,$$

for all $\alpha \in [0, \alpha_0]$, which is only possible if $P(x) = Q(x)$ for all $x \geq 0$.

□

Proof of Proposition 9: Note that the expectation,

$$\sum_{x=0}^{\infty} P(x)x^{\ell} \left(\frac{(x+1)P(x+1)}{\lambda P(x)} - 1\right) \leq 0,$$

by the Chebyshev rearrangement lemma, since it is the covariance between an increasing and a decreasing function. Rearranging this inequality gives,

$$E[X^{\ell+1}] = \sum_{x=0}^{\infty} P(x+1)(x+1)^{k+1} \leq \lambda \sum_{x=0}^{\infty} P(x) x^{\ell} = \lambda E[X^\ell],$$

as required. □
Proof of Proposition 10: To prove part (a), using Lemma 4, we have,

\[
E[(X + Y)^k] = E \left[ \sum_{\ell=0}^{k} \binom{k}{\ell} X^\ell Y^{k-\ell} \right]
= \sum_{\ell=0}^{k} \binom{k}{\ell} E[X^\ell] E[Y^{k-\ell}]
\leq \sum_{\ell=0}^{k} \binom{k}{\ell} \lambda^\ell \mu^{k-\ell}
= (\lambda + \mu)^k.
\]

It is straightforward to check, using Lemma 3, that \( T_\alpha P \in PB(\alpha \lambda) \).

To prove part (b), using Lemma 4, Pascal’s identity and relabelling, yields,

\[
E[(X + Y)^{k+1}] = E \left[ \sum_{\ell=0}^{k+1} \binom{k+1}{\ell} X^\ell Y^{k+1-\ell} \right]
= \sum_{\ell=0}^{k+1} \binom{k+1}{\ell} E[X^\ell Y^{k+1-\ell}]
\leq \sum_{\ell=0}^{k} \binom{k}{\ell} \lambda E[X^\ell] E[Y^{k+1-\ell}]
+ \sum_{\ell=0}^{k} \binom{k}{\ell} \mu E[X^{k+1-\ell}] E[Y^\ell]
= (\lambda + \mu) E[(X + Y)^k].
\]

The second property is again easily checked using Lemma 3.

Proof of Theorem 14: In order to apply Proposition 15 with \( P^*n \) in place of \( P \) and \( \alpha = 1/n \), we need to check that \( D(P^*n \parallel P o(\lambda)) \) is finite. Let \( S_n \) denote the sum of \( n \) i.i.d. random variables \( X_i \sim P \), so that \( P^*n \) is the distribution of \( S_n \). Similarly, \( P o(\lambda) \) is the sum of \( n \) independent \( P o(\lambda) \) variables. Therefore, using the data-processing inequality \[8\] as in \[24\] implies that \( D(P^*n \parallel P o(\lambda)) \leq nD(P \parallel P o(\lambda)) \), which is finite by assumption.

Proposition 15 gives,

\[
D(T_{1/n}(P^*n) \parallel P o(\lambda)) \leq \frac{1}{2n^2(1 - 1/n)} + E[(S_n/n) \log(S_n/n)] - \lambda \log \lambda.
\]

By the law of large numbers, \( S_n/n \rightarrow \lambda \) a.s., so \( (S_n/n) \log(S_n/n) \rightarrow \lambda \log \lambda \) a.s., as \( n \rightarrow \infty \). Therefore, to complete the proof it suffices to show that \( (S_n/n) \log(S_n/n) \) converges to \( \lambda \log \lambda \) also in \( L^1 \), or, equivalently, that the sequence \( \{T_n = (S_n/n) \log(S_n/n)\} \) is uniformly integrable. We will actually show that the nonnegative random variables \( T_n \) are bounded above by a different uniformly integrable sequence.
Indeed, by the log-sum inequality,

\[ T_n = \sum_{i=1}^{n} \frac{X_i}{n} \log \left( \frac{\sum_{i=1}^{n} \frac{X_i}{n}}{\sum_{i=1}^{n} \frac{1}{n}} \right) \]

\[ \leq \frac{1}{n} \sum_{i=1}^{n} X_i \log X_i. \tag{38} \]

Arguing as in the beginning of the proof of Proposition \[15\] shows that the mean \( \mu = E[X_i \log X_i] \) is finite, so the law of large numbers implies that the averages in (38) converge to \( \mu \) a.s. and in \( L^1 \). Hence, they form a uniformly integrable sequence; this implies that the \( T_n \) are also uniformly integrable, completing the proof.

**Proof of Theorem \[18\]**: The proof is similar to that of Theorem \[14\] so some details are omitted. For each \( n \geq 1 \), let \( \lambda^{(n)} = \frac{1}{n} \sum_{i=1}^{n} \lambda_i \) and write \( S_n = \sum_{i=1}^{n} X_i \), where the random variables \( X_i \) are independent, with each \( X_i \sim P_i \).

First, to see that \( D(P^{(n)} || \text{Po}(n\lambda^{(n)})) \) is finite, applying the data-processing inequality \[8\] as in \[24\] gives, \( D(P^{(n)} || \text{Po}(n\lambda^{(n)})) \leq \sum_{i=1}^{n} D(P_i || \text{Po}(\lambda_i)) \), and it is easy to check that each of these terms is finite because all \( P_i \) have finite second moments. As before, Proposition \[15\] gives,

\[ D(T_{1/n}(P^{(n)} || \text{Po}(\lambda^{(n)}))) \leq \frac{1}{2n^2(1 - 1/n)} + E[(S_n/n) \log(S_n/n)] - \lambda^{(n)} \log \lambda^{(n)}. \tag{39} \]

Letting \( Y_i = X_i - \lambda_i \) for each \( i \), the independent random variables \( Y_i \) have zero mean and,

\[ \sum_{i=1}^{\infty} \frac{1}{i^2} E(Y_i^2) = \sum_{i=1}^{\infty} \frac{1}{i^2} \text{Var}(X_i^2) \leq \sum_{i=1}^{\infty} \frac{1}{i^2} E(X_i^2), \]

which is finite by assumption (b). Then, by the general version of the law of large numbers on [11, p. 239], \( \frac{1}{n} \sum_{i=1}^{n} Y_i \to 0 \), a.s., and hence, by assumption (a), \( S_n/n \to \lambda \) a.s., so that also, \( (S_n/n) \log(S_n/n) \to \lambda \log \lambda \) a.s., as \( n \to \infty \). Moreover, since \((x \log x)^{4/3} \leq x^2\) for every integer \( x \geq 1 \), we have,

\[ E \left\{ \left( \frac{S_n}{n} \log \frac{S_n}{n} \right)^{4/3} \right\} \leq E \left\{ \left( \frac{S_n}{n} \right)^2 \right\} \]

\[ = \frac{1}{n^2} \sum_{i=1}^{n} E(X_i^2) + \frac{1}{n^2} \sum_{1 \leq i \neq j \leq n} E(X_i)E(X_j) \]

\[ \leq \sum_{i=1}^{n} \frac{1}{i^2} E(X_i^2) + (\lambda^{(n)})^2, \]

which is uniformly bounded over \( n \) by our assumptions. Therefore, the sequence \{\((S_n/n) \log(S_n/n)\)\} is bounded in \( L^p \) with \( p = 4/3 > 1 \), which implies that it is uniformly integrable, therefore it converges to \( \lambda \log \lambda \) also in \( L^1 \), so that, \( D(T_{1/n}(P^{(n)}) || \text{Po}(\lambda^{(n)})) \to 0 \) as \( n \to \infty \).

Finally, recalling once more that the Poisson measures form an exponential family, they satisfy a Pythagorean identity \[8\], so that

\[ D(T_{1/n}(P^{(n)}) || \text{Po}(\lambda)) = D(T_{1/n}(P^{(n)}) || \text{Po}(\lambda^{(n)})) + D(\text{Po}(\lambda^{(n)}) || \text{Po}(\lambda)), \]

where the first term was just shown to go to zero as \( n \to \infty \), and the second term is actually equal to,

\[ \lambda^{(n)} \log \frac{\lambda^{(n)}}{\lambda} + \lambda - \lambda^{(n)}, \]
which also vanishes as \( n \to \infty \) by assumption (a).

**Proof of Proposition 26**: Let \( X_\alpha \) and \( Z \) denote independent random variables with distributions \( T_\alpha P \) and \( \text{Po}((1 - \alpha)\lambda) \), respectively. Then from the definitions, and using Lemmas 4 and 3,

\[
E[P_\lambda^k(X_\alpha,\lambda)] = \frac{1}{(\lambda^k k!)^{1/2}} \sum_{\ell=0}^k (-\lambda)^{k-\ell} \binom{k}{\ell} \left\{ \sum_{m=0}^\ell \binom{\ell}{m} E(X^m_\alpha) E(Z^{\ell-m}) \right\}
\]

where we have used the fact that the factorial moments of a \( \text{Po}(t) \) random variable \( Z_t \) satisfy, \( E[Z_n t] = t^n \).

Simplifying and interchanging the two sums,

\[
E[P_\lambda^k(X_\alpha,\lambda)] = \frac{1}{(\lambda^k k!)^{1/2}} \sum_{m=0}^k \binom{k}{m} \alpha^m E(X^m_\alpha) \sum_{\ell=m}^k \binom{k-m}{\ell-m} (-\lambda)^{k-\ell} ((1 - \alpha)\lambda)^{\ell-m}
\]

as claimed.

**Proof of Proposition 27**: First we have to prove that \( P/\text{Po}(\lambda) \in L^2 \). Assume \( P \) is Poisson bounded with ration \( \mu \), say. Using the bound in Lemma 13,

\[
\sum_{x=0}^\infty \text{Po}(\lambda, x) \left( \frac{P(x)}{\text{Po}(\lambda, x)} \right)^2 \leq \sum_{x=0}^\infty \text{Po}(\lambda, x) \left( \frac{\text{Po}(\mu, x) e^\mu}{\text{Po}(\lambda, x)} \right)^2 = e^\lambda \sum_{x=0}^\infty \frac{\mu^2/\lambda^x}{x!} = e^\lambda e^{\mu^2/\lambda},
\]

which is finite.

Now, recalling the general expansion (27), it suffices to show that \( \langle P/\text{Po}(\lambda), P_\lambda^k \rangle = E[P_\lambda^k(X)] \). Indeed, for \( Z \sim \text{Po}(\lambda) \),

\[
\langle P/\text{Po}(\lambda), P_\lambda^k \rangle = E \left( \frac{P(Z)}{\text{Po}(\lambda, Z)} P_\lambda^k(Z) \right) = E \left[ P_\lambda^k(X) \right],
\]

as required.

**Proof of Proposition 30**: We need the following simple lemma; for a proof see, e.g., [13].

**Lemma 40**: If

\[
F(m, x) = \sum_{\ell=0}^m \binom{x}{\ell} (-1)^\ell
\]
then
\[
\begin{align*}
F(m, x) & \geq \delta_x \text{ for } m \text{ even}, \\
F(m, x) & \leq \delta_x \text{ for } m \text{ odd}.
\end{align*}
\]

Turning to the proof of Proposition 30 assume \( X \sim P \) is Poisson bounded with ratio \( \lambda \). Then the series in the statement converges, since
\[
\frac{1}{x!} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{E[X^{x+\ell}]}{\ell!} \leq \frac{1}{x!} \sum_{\ell=0}^{\infty} \frac{\lambda^{x+\ell}}{\ell!} = \text{Po}(\lambda, x) < \infty.
\]

For \( m \) even we have,
\[
\delta_{z-x} \leq \sum_{\ell=0}^{m} \left( z - x \right) (-1)^\ell,
\]

therefore,
\[
\left( \frac{z}{x} \right) \delta_{z-x} \leq \sum_{\ell=0}^{m} \left( \frac{z}{x} \right) \left( z - x \right) (-1)^\ell = \frac{1}{x!} \sum_{\ell=0}^{m} (-1)^\ell \frac{z^{x+\ell}}{\ell!}.
\]

Multiplying by \( P(z) \) and summing over \( z \),
\[
P(z) = \sum_{z=0}^{\infty} P(z) \left( \frac{z}{x} \right) \delta_{z-x}
\]
\[
\leq \sum_{z=0}^{\infty} P(z) \frac{1}{x!} \sum_{\ell=0}^{m} (-1)^\ell \frac{z^{x+\ell}}{\ell!}
\]
\[
= \frac{1}{x!} \sum_{\ell=0}^{m} (-1)^\ell \frac{E[X^{x+\ell}]}{\ell!}.
\]

A similar argument holds for \( m \) odd.

Proof of Theorem 37: Let \( X_\alpha \) have distribution \( T_\alpha P \). Using Lemma 3, Proposition 30 and the fact that \( X \) is ultra bounded, the score function of \( X_\alpha \) can be bounded as,
\[
\rho_{X_\alpha}(z) = \frac{(z + 1)T_\alpha P(z + 1)}{\alpha T_\alpha P(z)} - 1
\]
\[
\leq \frac{(z + 1)E[X^{z+1}] / (z + 1)!}{\alpha \lambda \left( E[X^z] - E[X^{z+1}] \right) / z!} - 1
\]
\[
= \frac{\alpha^{z+1}E[X^{z+1}]}{\alpha \lambda \left( E[X^{z+1}] - \alpha^{z+1}E[X^{z+1}] \right)} - 1
\]
\[
= \left[ \frac{E[X^z]}{E[X^{z+1}]} \right]^{-1} - 1
\]
\[
\leq \left( 1 - \lambda \alpha \right)^{-1} - 1
\]
\[
= \frac{\alpha \lambda}{1 - \alpha \lambda}.
\]

Since the lower bound \( \rho_{X_\alpha}(z) \geq -1 \) is obvious, it follows that,
\[
\rho_{X_\alpha}(z)^2 \leq 1, \quad \text{for all } \alpha > 0 \text{ small enough.} \tag{40}
\]
We express \( K(T_\alpha P) \) in three terms:

\[
K(T_\alpha P) = \lambda \alpha \sum_{z=0}^{\kappa-2} T_\alpha P(z) \rho_{X_\alpha}(z)^2 + \lambda \alpha T_\alpha P(\kappa-1) \rho_{X_\alpha}(\kappa-1)^2 + \lambda \alpha \sum_{z=\kappa}^\infty T_\alpha P(z) \rho_{X_\alpha}(z)^2. \tag{41}
\]

For the third term note that, applying Markov’s inequality to the function \( f(x) = x(x-1) \cdots (x-\kappa+1) \), which increases on the integers, we obtain,

\[
\Pr\{X_\alpha \geq \kappa\} \leq \frac{E[X_\alpha^\kappa]}{\kappa!} = \frac{\alpha^\kappa E[X_\alpha^\kappa]}{\kappa!} \leq \frac{(\alpha \lambda)^\kappa}{\kappa!}.
\]

Therefore, using this and (40), for small enough \( \alpha > 0 \) the third term in (41) is bounded above by,

\[
\alpha \lambda \frac{(\alpha \lambda)^\kappa}{\kappa!} \to 0,
\]

which, divided by \( \alpha^\kappa \), tends to zero as \( \alpha \to 0 \).

For the other two terms we use the full expansion of Proposition 30 together with Lemma 3 to obtain a more accurate expression for the score function,

\[
\rho_{X_\alpha}(z) = \frac{(z+1)T_\alpha P(z+1) - \alpha \lambda T_\alpha P(z)}{\alpha \lambda T_\alpha P(z)}
\]

\[
= \frac{1}{\alpha \lambda} \sum_{\ell=0}^\infty (-1)^\ell \frac{E[X_{\alpha}^{z+1+\ell}]}{\ell!} - \alpha \lambda \sum_{\ell=0}^\infty (-1)^\ell \frac{E[X_{\alpha}^{z+\ell}]}{\ell!}
\]

\[
= \frac{\alpha \lambda}{\alpha \lambda} \sum_{\ell=0}^\infty (-1)^\ell \frac{\alpha^\ell (E[X_{\alpha}^{z+1+\ell}] - \lambda E[X_{\alpha}^{z+\ell}])}{\ell!}
\]

\[
\times \lambda \sum_{\ell=0}^\infty (-1)^\ell \frac{\alpha^\ell E[X_{\alpha}^{z+\ell}]}{\ell!}.
\]

Since, by assumption, \( E[X_{\alpha}^{z+1+\ell}] - \lambda E[X_{\alpha}^{z+\ell}] = 0 \) for \( z + \ell < \kappa - 1 \), the first terms in the series in the numerator above vanish. Therefore,

\[
\rho_{X_\alpha}(z) = \alpha^{\kappa-z-1} \sum_{\ell=0}^\infty (-1)^{\ell+\kappa-z-1} \alpha^\ell \frac{E[X_{\alpha}^{\ell+z}] - \lambda E[X_{\alpha}^{\ell+z-1}]}{\ell!} / (\ell + \kappa - z - 1)!.
\]

For \( z \leq \kappa-2 \), the numerator and denominator above are both bounded functions of \( \alpha \), and the denominator is bounded away from zero (because of the term corresponding to \( \ell = 0 \)). Therefore, for each \( 0 \leq z \leq \kappa-2 \), the score function \( \rho_{X_\alpha}(z) \) is of order \( \alpha^{\kappa-z-1} \). For the first term in (41) we thus have,

\[
\lambda \alpha \sum_{z=0}^{\kappa-2} T_\alpha P(z) \rho_{X_\alpha}(z)^2 = \alpha \sum_{z=0}^{\kappa-2} O(\alpha^z) O(\alpha^{2\kappa-2z-2}) = O(\alpha^{\kappa+1}),
\]

which, again, when divided by \( \alpha^\kappa \), tends to zero as \( \alpha \to 0 \).

Thus only the second term in (41) contributes. For this term, we similarly obtain,

\[
\lim_{\alpha \to 0} \rho_{X_\alpha}(\kappa-1) = \lim_{\alpha \to 0} \frac{\sum_{j=0}^\infty (-1)^j \alpha^j (E[X_{\alpha}^{j+\kappa}] - \lambda E[X_{\alpha}^{j+\kappa-1}]) / j!}{\lambda \sum_{j=0}^\infty (-1)^j \alpha^j E[X_{\alpha}^{j+\kappa}] / j!}
\]

\[
= \frac{E[X_{\alpha}^\kappa] - \lambda E[X_{\alpha}^{\kappa-1}]}{\lambda E[X_{\alpha}^{\kappa-1}]}
\]

\[
= \frac{E[X_{\alpha}^\kappa] - \lambda^\kappa}{\lambda^\kappa}, \tag{42}
\]

For the first term in (41) we thus have,
and,

\[
\lim_{\alpha \to 0} \frac{\alpha T_\alpha P(\kappa - 1)}{\alpha^\kappa} = \lim_{\alpha \to 0} \frac{\alpha \lambda \sum_{j=0}^{\infty} (-1)^j E \left[ (T_\alpha X)^{\kappa-1+j} \right] / j!}{(\kappa - 1)! \alpha^\kappa} = \lim_{\alpha \to 0} \frac{\lambda \sum_{j=0}^{\infty} (-1)^j \alpha^j E [X^{\kappa-1+j}] / j!}{(\kappa - 1)!} = \frac{\lambda^\kappa}{(\kappa - 1)!}.
\]

Finally, combining the above limits with (41) yields,

\[
\lim_{\alpha \to 0} \frac{K(T_\alpha X)}{\alpha^\kappa} = \frac{\lambda^\kappa}{(\kappa - 1)!} \left( \frac{E [X^\kappa] - \lambda^\kappa}{\lambda^\kappa} \right)^2 = \kappa \left( \frac{E [X^\kappa] - \lambda^\kappa}{\lambda^{\kappa/2} (\kappa!)^{1/2}} \right)^2 = \kappa E [P_\kappa (X)]^2,
\]

as claimed.

Proof of Lemma 35: The key is to observe that for \( Y \) ULC, since \( P(y+1)(y+1)/P(y) \) is decreasing in \( y \), and \( y \) is increasing in \( y \), there exists an integer \( y_0 \) such that \( P(y+1)(y+1) \leq y_0 P(y) \) for \( y \geq y_0 \) and \( P(y+1)(y+1) \geq y_0 P(y) \) for \( y < y_0 \). Hence:

\[
\sum_{y=z+1}^{\infty} P(y)(y - y_0) = P(z+1)(z+1) + \sum_{y=z+1}^{\infty} (P(y+1)(y+1) - y_0 P(y)) \leq (z+1)P(z+1), \text{ for } z \geq y_0;
\]

\[
\sum_{y=0}^{z} P(y)(y_0 - y) = P(z+1)(z+1) - \sum_{y=0}^{z} (P(y+1)(y+1) - y_0 P(y)) \leq (z+1)P(z+1), \text{ for } z \leq y_0 - 1.
\]

Further, by Cauchy-Schwarz, for \( y \geq y_0 \),

\[
(g(y) - g(y_0))^2 = \left( \sum_{z=y_0}^{y-1} \Delta g(z) \right)^2 \leq (y - y_0) \left( \sum_{z=y_0}^{y-1} \Delta g(z)^2 \right), \quad (44)
\]

while for \( y \leq y_0 - 1 \),

\[
(g(y) - g(y_0))^2 = \left( \sum_{z=y}^{y_0-1} \Delta g(z) \right)^2 \leq (y_0 - y) \left( \sum_{z=y}^{y_0-1} \Delta g(z)^2 \right), \quad (45)
\]

This means that (with the reversal of order of summation justified by Fubini, since all the terms have the
same sign),
\[
\sum_{y=0}^{\infty} P(y) (g(y) - \mu)^2 \\
\leq \sum_{y=0}^{\infty} P(y) (g(y) - g(y_0))^2 \\
= \sum_{y=0}^{y_0-1} P(y) (g(y) - g(y_0))^2 + \sum_{y=y_0}^{\infty} P(y) (g(y) - g(y_0))^2 \\
\leq \sum_{y=0}^{y_0-1} P(y)(y_0 - y) \left( \sum_{z=y}^{y_0-1} \Delta g(z)^2 \right) + \sum_{y=y_0}^{\infty} P(y)(y - y_0) \left( \sum_{z=y_0}^{y-1} \Delta g(z)^2 \right) \\
\leq \sum_{z=0}^{y_0-1} \Delta g(z)^2 \left( \sum_{y=0}^{z} P(y)(y_0 - y) \right) + \sum_{z=y_0}^{\infty} \Delta g(z)^2 \left( \sum_{y=z+1}^{\infty} P(y)(y - y_0) \right) \\
\leq \sum_{z=0}^{\infty} (\Delta g(z))^2 P(z + 1)(z + 1),
\]
and the result holds. Note that the inequality in (46) follows by (44) and (45), and the inequality in (47) by the discussion above.
