Cyanide-Bridged Polynuclear and One-Dimensional 
Fe$^{III}$-Mn$^{III/II}$ Bimetallic Complexes Based-on 
Pentacyanoferroferrite(III) Building Block: Synthesis, 
Crystal Structures, and Magnetic Properties

Abstract

In this contribution, based-on the structurally confirmed pentacyanometallate (PPh$_4$)$_2$[Fe(CN)$_5$(imidazole)]·(imidazole)·H$_2$O (1) and the manganese compounds [Mn(L)(H$_2$O)$_2$]ClO$_4$ (L = N,N-ethylenebis(3-methoxysalicylideneiminate) or [Mn(MAC)(H$_2$O)Cl]ClO$_4$ (MAC = 2,13-dimethyl-3,6,9,12,18-pentaazabicyclo-[12.3.1]octadeca-1(18),2,12,14,16-pentaene), two new cyanide-bridged bimetallic Fe$^{III}$-Mn$^{III/II}$ complexes [[Mn(L)(H$_2$O)]$_3$[Fe(CN)$_5$(imidazole)]](ClO$_4$)$_2$ (2) and [[Mn(MAC)][[Fe(CN)$_5$(imidazole)]]·CH$_3$OH]$_n$ (3) were successfully synthesized and characterized by elemental analysis, IR spectroscopy and X-ray structure determination. Single X-ray diffraction analysis reveals the cationic FeMn$_3$ tetranuclear entity for complex 2, which can be further assembled into supramolecular 1D ladder-like double chain by the strong intermolecular hydrogen bond interactions. For complex 3, it can be structurally characterized as neutral one-dimensional linear single infinite chain. The magnetic investigations discover the ferromagnetic coupling between the Fe$^{III}$-Mn$^{III}$ units in complex 2 and the antiferromagnetic coupling in complex 3 between the Fe$^{III}$-Mn$^{II}$ units through the bridging cyanide group, respectively.

Keywords: Pentacyanoferroferrite; cyanide-bridged; crystal structure; magnetic property

1. Introduction

In the past several decades, due to their great potential in high-tech fields including quantum compute, information storage, etc., more and more attention have been paid to the research of the molecular-based magnetism. As one of the most important building block for the rational construction of molecular magnetic systems, cyanide-bridged magnetic complexes have all along received intense attention since their readily controlled molecular topological structures and theoretically predicted magnetic properties. Up to now, a great deal of cyanide-bridged molecular materials structural ranging from 0-dimensional cluster to three-dimensional beautiful networks have been rationally designed and structurally characterized. Among those, some systems with interesting magnetic properties, such as single chain magnets (SCMs) and single molecule magnets (SMMs), spin crossover materials, high-Tc magnets, photomagnetic materials, ferromagnetic materials, chirality magnets et al, have been detailed magnetically studied. One of the most successful strategies used to prepare cyanide-bridged magnetic complexes is based on the assemble reactions of the decorated polycyanometallates [M(L)(CN)$_x$]$_n^+$ ((M = Fe, Cr, W, Mo, Mn, Ru; x = 1–8, L = mono- or multi-dentate organic ligand) with other counterpart paramagnetic metal compounds. Because the blocking organic ligand(s) in either the cyano precursors or the counterpart assemble segments can contribute obvious steric effect and therefore efficiently lower the dimen-
sionality of the target product, many low-dimensional \( [M(L)(CN)]^{10-} \)-based complexes have been expectedly obtained.36–38 Among all the polycyanoferrite(III) building blocks, the pentacyanoferrite(III) \( [Fe(L)(CN)]^{5-} \) ( \( L' = \) monodentate ligand) precursors have been comparatively limited employed in cyanide-bridged molecule magnetism field. 39–43 In this paper, we are focusing on the designed preparation of new cyanide-bridged magnetic complexes with the exploitation of pentacyanideferrite(III) compound \( [Fe(CN)]_5^{2–} \) as building block and manganese compounds as assemble segments (Scheme 1). The synthesis, structural characterization and magnetic study for the two new obtained Mn\(^{II/III}\)-Fe\(^{III}\) bimetallic magnetic complexes \( \{[Mn(L)(H_2O)]_3[Fe(CN)_5(imidazole)]ClO_4\} \) (2) and \( \{[Mn(MAC)][Fe(CN)_5(imidazole)],[CH_3OH]_n\} \) (3), as well as the structure of the cyano precursor \( (PPh_4)_2[Fe(CN)_5(imidazole)] \) · \( \cdot \) \( H_2O(1) \), will be presented in the current contribution.

2. Experimental Section

2.1. General Procedures and Materials

All the reactions were carried out at room temperature under air atmosphere with the solvents and chemicals used reagent grade without additional purification. \( [Ca(imidazole)(H_2O)][Fe(CN)_5(imidazole)] \) was prepared as black crystals according to the literature method for \( [Ca(1-CH_3im)(H_2O)][Fe(CN)_5(1-CH_3im)] \).41 \( [Mn(L)(H_2O)_2]ClO_4 \) (2) \( L = N,N\)-ethylenbis(3-methoxyxalicylideneinate) and \( [Mn(MAC)(H_2O)Cl]ClO_4 \) (MAC = 2,13-dimethyl-3,6,9,12,18-pentaazabicyclo-[12. 3.1]octadeca-1(18),2,12,14,16-pentaene) were available from the previous works.

Caution! KCN is hypertoxic and hazardous. Perchlorate salts with organic ligands are potentially explosive. They should be handled in small quantities with care.

Synthesis of \( (PPh_4)_2[Fe(CN)_5(imidazole)] \) · \( \cdot \) \( H_2O(1) \):
\[ [Ca(imidazole)(H_2O)][Fe(CN)_5(imidazole)] \] (1.9 g, 5 mmol) was dissolved in water (20 ml), and PPh\(_4\)Br (4.0 g, 10 mmol) was added to the solution. Then, the mixture was stirred in the dark overnight before the yellow powder formed was filtered out. Yield: 3.57g (70%). Recrystallization of the powder in MeOH afforded yellow single crystals. Main IR bands (cm\(^{-1}\)): 2110, 2121(s, \( \nu \) C≡N). The elemental analysis (experimental and theoretical) and some physical properties are given in Table 1.

Synthesis of \( \{[Mn(L)(H_2O)]_3[Fe(CN)_5(imidazole)]\} \) (ClO\(_4\)) (2):
The complex was prepared by using three layers diffusion procedure. A solution containing \( (PPh_4)_2[Fe(CN)_5(imidazole)] \) · \( \cdot \) \( H_2O(102 mg, 0.10 mmol) dissolved in 5mL H_2O was laid in the bottom of a tube, and then carefully upon addition of a mixture solvent of water and methanol (5 mL) with a ratio of 1:1. Finally, a solution of \( [Mn(L)(H_2O)_2]ClO_4 \) (112 mg, 0.2 mmol) in 5 mL of CH\(_3\)OH was carefully added to the top of the mixture solvent layer above formed. The dark-brown crystal appeared in the middle of the tube was filtered out 2–3 weeks later, washed by methanol and dried in air. \( \{[Mn(L)(H_2O)]_3[Fe(CN)_5(imidazole)]\} \) ClO\(_4\) (2): Yield: 49.6 mg (44.6%). Main IR bands (cm\(^{-1}\)): 2150(s, \( \nu \) C≡N), 2122 (s, \( \nu \) C≡N), 1620 (m, \( \nu \) C=N), 1100 (s, \( \nu \) Cl=O). The elemental analysis (experimental and theoretical) and some physical properties are given in Table 1.

Synthesis of \( \{[Mn(MAC)][Fe(CN)_5(imidazole)],[CH_3OH]_n\} \) (3):
A solution of \( (PPh_4)_2[Fe(CN)_5(imidazole)] \) · \( \cdot \) \( H_2O(102 mg, 0.10 mmol) dissolved in 5mL H_2O was laid in the bottom of a tube, and then carefully upon addition of a mixture solvent of water and methanol (5 mL) with a ratio of 1:1. Finally, a solution of \( [Mn(MAC)(H_2O)]ClO_4 \) (48 mg, 0.1 mmol) in 5 mL of CH\(_3\)OH was carefully added to the top of the mixture solvent layer above formed. The yellow crystal appeared in the middle of the tube 2–3 weeks later, which was filtered out, washed by methanol and dried in air. \( \{[Mn(MAC)][Fe(CN)_5(imidazole)],[CH_3OH]_n\} \) (3): Yield: 43.6 mg, 70.9%. Main IR bands (cm\(^{-1}\)): 2150, 2120(s, \( \nu \) C≡N), 1630 (m, \( \nu \) C≡N). The elemental analysis (experimental and theoretical) and some physical properties are given in Table 1.
2. 2. X-ray Data Collection and Structure Refinement

Single crystals with suitable dimensions for complexes 1–3 for X-ray diffraction analysis were mounted on the glass rod and the crystal data were collected on a Bruker APEX II CCD area-detector with a Mo Ka sealed tube ($\lambda = 0.71073 \, \text{Å}$) at room temperature using a $\omega$ scan mode. The structures were solved by direct methods and expanded using Fourier difference techniques with the SHELXTL-2018/3 program package.\(^{45}\) While all the hydrogen atoms were introduced as fixed contributors, the non-hydrogen atoms were refined anisotropically with anisotropic displacement coefficients. Hydrogen atoms except some ones from the solvent molecules were assigned isotropic displacement coefficients $U(H) = 1.2U(C)$ or $1.5U(C)$ and their coordinates were allowed to ride on their respective carbon/nitrogen atoms using SHELXL 2018/3. For the solvent H atoms, they were refined isotropically with fixed $U$ values, during which the DFIX command was used to rationalize the bond parameter. The supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. Details of the crystallographic parameter, data collection, and refinement are summarized in Table 2.

3. Results and Discussion

3. 1. Synthesis

With comparison to the widely used hexacyanoiron(III) in cyanide-bridged molecular magnetism field, the pentacyanoiron(III) has been relatively less used to assemble magnetic complex, and only several pentacyanoiron(III)-based heterometallic magnetic systems have been reported.\(^{39–42, 45}\) By using the three-layers diffusion method, which has been shown to be a powerful way for growing single crystals,\(^{43–44}\) one cationic tetranuclear Fe\(^{3+}\)Mn\(^{2+}\) entity and one neutral one-dimensional Fe\(^{3+}\)-Mn\(^{1+}\) complex have been successfully prepared from the reactions of [Fe(imidazole)(CN)]\(^{2–}\) and the manganese

Schiff-base [Mn(L)]\(^+\) or the macrocyclic [Mn(MAC)]\(^{2+}\) compound, respectively (Scheme 2).

The cyanide-bridged heterometallic complexes have been characterized by IR spectroscopy. Compared to the cyanide precursor with only one peak at about 2125 cm\(^{-1}\), two sharp peaks in the IR spectra of complexes 2 and 3 due to the cyanide-stretching vibration \(^{[42, 43]}\) were observed at about 2120 and 2160 cm\(^{-1}\), respectively, indicating the presence of bridging and nonbridging cyanide ligands in these complexes. For complex 2, the strong peak centered at 1100 cm\(^{-1}\) is attributed to the free ClO\(_4^−\) anions.

### 3. 2. Crystal Structure Descriptions

#### The crystal structure of the cyano precursor:

The selected bond lengths and angles for complex 1 are given in Table 3. The molecular structure and the H-bond resulted 1D supramolecular structure are shown in Figures 1 and 2, respectively. The asymmetric unit of (PPh\(_4\))\(_2\)[Fe(CN)\(_5\)imidazole]·(imidazole)·H\(_2\)O (1), which crystallizes in monoclinic space group P2/c, is comprised

Symmetry transformations used to generate equivalent atoms: #1 x, -y+1/2, z+1/2; #2 x, -y+1/2, z+1/2; #3 x+1, y, z (1); #1 x, -y, z-1/2 (2).

by five moieties: an anionic Fe complex, one water molecule, one imidazole molecule and two tetraphenylphosphonium cations. The [Fe(CN)₅(imidazole)]²⁻ anion contains a low-spin Fe³⁺ center coordinated by one imidazole unit and five CN units, in which four CN groups occupy the four equatorial positions with the fifth CN group collinearly axial with the imidazole group. The Fe-C bond lengths in a narrow range 1.925(3)–1.958(3) Å are slightly shorter than the Fe-N(imidazole) bond with the value 2.002(2) Å. The Fe≡C=N angles are within the range of 175.4(3)–179.3(3)°, indicating the almost linear conformation of these atoms. Under the O-H...N H-bond interactions from the host anion and the co-crystallized water molecules (Table 4), the [Fe(CN)₅(imidazole)]²⁻ moieties are linked into 1D supramolecular single chain structure (Figure 2).

3.3. The Crystal Structure of the Complex 2

The cationic tetranuclear structure and the one-dimensional ladder-like double-chain structure formed by the intermolecular hydrogen bonds for complex 2 are shown in Figures 3 and 4, respectively. The selected important bond parameters for complex 2 are listed in Table 5.

The complex 2 is a neutral tetranuclear cluster comprised by the cationic FeMn₃ unit and an additional disordered ClO₄⁻ as counter anion. In the FeMn₃ core, [Fe(imidazole)(CN)₅]²⁻ acting as a mer-₃-coordinating-donor building block is coordinated by three [Mn(L)(H₂O)]⁺ through three cyanide groups and forming a T-like arrangement. Each [Mn(L)(H₂O)]⁺ moiety has an elongated octahedral geometry with Jahn-Teller distortion along the (H₂O)-Mn-N_cyanide axis, in which the four equatorial positions are coordinated by N₂O₂ unit from the Schiff-base ligand and the two axial ones occupied by one N atom of the bridge cyanide group and one O atom from the H₂O molecule. The average Mn-N_Schiff-base/O_Schiff-base bond lengths are 1.988(5) Å and 1.874(3) Å, which are obviously shorter than the Mn-N_cyanide 2.245(5) Å and Mn-O_water 2.298(4) Å. The Mn(1)-N(1)-C(1) angle (156.5(4)°) is slightly bigger than the other two Mn-N≡C angles with values of 146.4(4)° and 149.2(4)°. The intramolecular Mn₃⁺ distances through bridge-cyanides are very close to each other with values 5.100, 5.100 and 5.154 Å, respectively, which are slightly longer than the shortest intermo-

Figure 4. One-dimensional double-chain structure of complex 2 formed by intermolecular hydrogen-bond interactions. All the H atoms except those used to form hydrogen bonds and the balance ClO₄⁻ have been omitted for clarity.
lecular metal-metal separation. Because of the excellent encapsulation ability of the O₄ compartment for the water molecule, one-dimensional ladder-like double chain structure is formed under the help of the intermolecular H-bond interactions (Table 3) between the O₄H₂O atoms and the O atoms of the Schiff-base ligand.

3. 4. The Crystal Structure of the Complex 3

The asymmetry binuclear unit and 1D neutral chain structure of complex 3 is presented in Figure 5. The important bond parameters are given in Table 5. As can be found, complex 3 possesses one-dimensional neutral single chain structure comprising of the repeating [-NC-Fe(imidazole)(CN)₃-CN-Mn(MAC)-] units. In this complex, each [Fe(imidazole)(CN)₅]²⁻ unit, functioning as bidentate ligand through its two cyanide groups in trans position, connects the Mn(II) ions of two independent macrocyclic manganese units. Similar to that in compounds 1 and 2, the coordination geometry of the Fe atom is also a slightly distorted octahedral geometry with the macrocyclic ligand forming the equatorial plane. The five equatorial positions are occupied by N atoms from the macrocyclic ligand, while the axial positions are occupied by two N atoms of the bridging cyanide groups. The Mn-N distances within the range 2.196–2.299 Å are with no conspicuous with the Mn-N distances (2.199(5) and 2.220(5) Å), indicating the only slightly distorted pentagonal-bipyramidal geometry of the Mn(II) ion. With comparison to the Fe-C≡N angle distributed in a very narrow range of 179.3(5)°–177.1(5)°, the bridging cyanide ligands coordinated to the Mn(II) ions in a bent fashion with the Mn-N≡C angles are 152.6(4)° and 161.7(5)°, respectively.

3. 5. The Magnetic Properties of Complexes 2 and 3

The temperature dependences of the $c_mT$ product per FeIII-MnIII and FeIII-MnII unit for 2 and 3 measured from 2 to 300 K under an applied magnetic field of 2000 Oe are shown in Figures 6 and 7. The $c_mT$ value at room temperature is 9.11 emu K mol⁻¹ ($\mu_{eff} = 8.57$ BM) for 2 and 4.33 emu K mol⁻¹ ($\mu_{eff} = 5.91$ BM) for 3, which are slightly
lower than the spin only value of 9.375/4.75 emu K mol\(^{-1}\) for uncoupled three high spin Mn(III) (\(S = 2\))/one high spin Mn(II) (\(S = 5/2\)) and one low spin Fe(III) (\(S = 1/2\)) based on \(g = 2.00\), respectively. For these two complexes, the \(c_mT\) values maintains nearly constant until the temperature lowering to 20 K for \(2\) and 50 K for \(3\). After that, the \(c_mT\) value for complex \(2\) starts to increase smoothly and reaches its highest value 10.12 emu K mol\(^{-1}\), and then decreases rapidly to the lowest value about 0.87 emu K mol\(^{-1}\) at 2 K. The suddenly decrease for the \(c_mT\) value in the low temperature range can maybe attributed to the comparable strong intermolecular H-bond interaction and/or the zero field spitting of the Mn(III) ion. Different from that for complex \(2\), the \(c_mT\) value of complex \(3\) presents the obvious decreasing tendency from 50 K, and attains its minimum value 2.19 emu K mol\(^{-1}\) at 2 K, implying the different coupling nature in these two complexes. The magnetic susceptibilities of \(2\) and \(3\) conform well to Curie-Weiss law and give the positive Weiss constant \(q = 1.87\) K, Curie constant \(C = 8.90\) emu K mol\(^{-1}\) for \(2\) and negative \(q = -1.90\) K, \(C = 4.54\) emu K mol\(^{-1}\) for \(3\). On the basis of the Weiss constant and with the combination of change tendency of \(c_m-T\) curves, the overall ferromagnetic magnetic coupling between Fe(III) and Mn(III) ions in complex \(2\) and antiferromagnetic coupling between Fe(III) and Mn(II) ion in \(3\) can be concluded.

In view of the situation that the three Mn-N≡C-Fe bridges are structurally independent and the coordination environment of the three Mn(III) ions are not completely same to each other with the Mn-N≡C angles 146.4(4)–156.1(4)° and the Mn-N\(_{\text{CN}}\) bond lengths 1.980(5)–2.253(5) Å, the simulation of the magnetic susceptibility for this compound should be based on three different \(J\) values (\(J_1 \neq J_2 \neq J_3\)), where the three \(J\) values represent the Mn(1)…Fe(1), Mn(2)…Fe(1) and Mn(3)…Fe(1) interactions through cyanide bridges, respectively. On the other hand, according to the method successfully employed to simulate the magnetic susceptibilities of 1D chain compound with alternating spins 1/2 and 2,\(^{30b}\) the one-dimensional chain structure of the complex \(3\) can be considered as isotropic Heisenberg chain containing alternating spins 1/2 and 5/2 with two antiferromagnetic exchange interactions \(J_1\) and \(J_2\). In this case, the magnetic susceptibility of this complex can be calculated rationally based on a closed ring cluster model consisting of five 1/2–5/2 spin pairs.

**Figure 6.** Left: The \(c_m-T\) (the solid line represents the best fit based on the parameters discussed in the text) and \(c_m\) curve for complex \(2\). Right: The field-dependent magnetization for complex \(2\).

**Figure 7.** Temperature dependence of \(c_m\) of complex \(3\) (the solid line represents the best fit based on the parameters discussed in the text). Inset: Field dependence of magnetization at 2 K (the dotted line is the Brillouin curve for antiferromagnetic coupled Fe(III) and Mn(II) ions with \(g = 2.00\)).

**Scheme 4.**

Evaluation of the exchange coupling between the iron(III) ion and manganese(III/II) ions bridged by cyanide group in complexes \(2\) and \(3\) are carried out by MAGPACK program.\(^{47}\) The best-fit parameters obtained are \(J_1 = 1.12, J_2 = 1.65, J_3 = 0.91\) cm\(^{-1}\), \(D = -1.81\) cm\(^{-1}\), \(g = 2.02, R =\)
= Σ(c_{obsd}T - c_{cald}T)^2/Σ(c_{obsd}T)^2 = 1.61 \times 10^{-5} \text{ for complex 2}
and J_1 = -1.34, J_2 = -0.54(1) \text{ cm}^{-1}, g = 1.99, R = 3.01 \times 10^{-5}
for complex 3, respectively. All the theoretical fitting results are comparable to those found in the previously reported cyanide-bridged Fe^{III}-Mn^{III/II} complexes.\textsuperscript{42-44, 48}
The field-dependent magnetizations measured up to 50 kOe at 2 K for complexes 2 and 3 are shown in Figure 6
and the inset of Figure 7, respectively. The field-dependent magnetization curve for complex 2 has a sigmoid shape,
implying maybe the metamagnetic behavior: The magnetization first increases slowly with increasing magnetic field
until 20 kOe because of the relatively strong intermolecular hydrogen bond interaction, then increases abruptly
for a phase transition at about 20 kOe, and finally attains the highest value about 7.45 Nb, which is slightly higher
than the saturated value for three Mn(III) ion (S = 2) and one low spin Fe(III) ion (S = 1/2). For complex 3, the magnetization quickly increases with the field increasing until about 15 kOe, then increases smoothly up to about 3.9 Nb
until 50 kOe. This data is very close to the saturated value of 4.0 Nb but obviously lower than the value of uncoupled low spin Fe(III) and Mn(II) based on g = 2.0, confirming again the overall antiferromagnetic coupling interaction between Fe(III) and Mn(II) ions bridged by cyanide group.

4. Conclusion
In summary, two new heterobimetallic cyanide-bridged complexes have been prepared with pentacyanoiron(III) as building block and manganese(III/II) compounds as the counterpart assemble segment. The single crystal X-ray analysis revealed the cationic tetranuclear FeMn$_3$ entity or one-dimensional infinite chain structure, respectively. For the polynuclear cluster, it can be self-complementary through coordinated aqua ligand from one complex and the free O$_4$ compartment from the neighboring complex, therefore giving interesting supramolecular one-dimensional ladders. The experimental and theoretical investigation on their magnetic properties disclose the ferro- or antiferromagnetic coupling in cyanide-bridged Fe^{III}-Mn^{III/II} units, respectively. The present results can further enrich the pentacyanometallate-based molecule magnetic system, which is helpful for fully discover the magneto-structural relation from the molecule magnetism.
