Abstract:
This article presents the inverse of the kernel operator associated with the complete quadratic Lyapunov-Krasovskii functional for coupled differential-functional equations when the kernel operator is separable. Similar to the case of time-delay systems of retarded type, the inverse operator is instrumental in control synthesis. Unlike the power series expansion approach used in the previous literature, a direct algebraic method is used here. It is shown that the domain of definition of the infinitesimal generator is an invariant subspace of the inverse operator if it is an invariant subspace of the kernel operator. The process of control synthesis using the inverse operator is described, and a numerical example is presented using the sum-of-square formulation.

Keywords: Lyapunov-Krasovskii functional, linear operator, time delay, sum-of-square.

1. INTRODUCTION

It is known that an accurate stability analysis using the Lyapunov approach requires a complete quadratic Lyapunov-Krasovskii functional. Such an approach was first implemented in the form of the discretized Lyapunov-Krasovskii functional method in Gu (1997), and a refined version was presented in Gu (2001). In this method, the kernel of the Lyapunov-Krasovskii functional is piecewise linear. An alternative approach is the Sum-Of-Squares (SOS) method presented in Peet et al. (2009). In the SOS method, the kernel is polynomial. In both approaches, the stability problem is reduced to a semi-definite programming problem, or more specifically, a linear matrix inequality problem.

For many practical systems, the number of state variables with delays is very small compared with the total number of state variables. For such systems, a special form of the coupled differential-difference equation formulation, or its generalized counterpart, the coupled differential-functional equation formulation proves to be much more efficient in numerical computation. The differential-difference formulations can also model systems of neutral type. The discretized Lyapunov-Krasovskii functional approach to stability of differential-difference equations is documented in Gu and Liu (2009), Gu (2010) and Li (2012), and the SOS formulation can be found in Zhang et al. (2011).

Control synthesis based on complete quadratic Lyapunov-Krasovskii functional stability conditions is still rare. An early example is Fridman (2002), in which a more limited class of Lyapunov-Krasovskii functional is used, and some parameter constraints are imposed. Recently, a synthesis based on the inverse of kernel operator associated with the Lyapunov-Krasovskii functional for time-delay systems of retarded type in the SOS formulation was developed in Peet and Papachristodoulou (2009b) and Peet (2013).

This paper extends the method by Peet et al. to coupled differential-functional equations. The inverse operator is derived using direct algebraic approach rather than the series expansion approach. The basic idea of such synthesis is outlined as follows.

Consider the coupled differential functional equations

\[
\dot{x}(t) = Ax(t) + By(t - r) + \int_r^0 H(\theta)y(t + \theta)d\theta, \quad (1)
\]

\[
y(t) = Cx(t) + Dy(t - r), \quad (2)
\]

where \( A \in \mathbb{R}^{n \times n}, B \in \mathbb{R}^{m \times n}, C \in \mathbb{R}^{m \times n}, H(\theta) \in \mathbb{R}^{m \times m}, D \in \mathbb{R}^{m \times n} \), and \( r > 0 \) is time delay, \( \mathbb{R}^n \) and \( \mathbb{R}^{m \times n} \) denote the set of real vectors and matrices with \( m \times n \) dimensions, respectively. The initial conditions are defined as

\[
x(0) = \psi \in \mathbb{R}^n, \quad y_0 = \phi \in PC(r, m),
\]

where \( y_t \) represents a shift and restriction of \( y(t) \) defined by \( y_t(\theta) = y(t + \theta), -r \leq \theta \leq 0 \). \( PC(r, m) \) represents the set of piecewise continuous functions from \([-r, 0]\) to \( \mathbb{R}^m \). Let
\[
Z := \mathbb{R}^n \times PC(r, m).
\]
The solutions to the system described by (1) and (2) may be represented by a strongly continuous semigroup \( C_0 \)-semigroup) \( S : Z \rightarrow Z \).
\[
z(t) = S(t - r)z(\tau).
\]
System (1)-(2) may be written as an abstract differential equation on \( Z \),
\[
\dot{z} = Az + Fu.
\]
Critical to implementing the above idea is the inversion of the linear operator \( \mathcal{P} \). Unfortunately, such an inversion is not easy in general. It turns out that a relatively simple expression for \( \mathcal{P}^{-1} \) is possible when \( \mathcal{P} \) is separable, as is utilized in (Peet and Papachristodoulou , 2009b) to carry out control synthesis for time-delay systems of retarded type. In this paper, we present the inversion of \( \mathcal{P} \) for coupled differential-functional equations. Unlike the series expansion method used in (Peet, 2013), a direct algebraic approach is used here. Control synthesis is also described, and a numerical example is presented to illustrate the method.

2. PRELIMINARIES

Consider the coupled differential functional equations given in (1) and (2).

Stability of such a system may be verified using a complete Lyapunov-Krasovskii functional of the following form,
\[
V(\psi, \phi) = r\psi^T P\psi + 2r\psi^T \int_{-r}^{0} Q(\eta)\phi(\eta)d\eta + \int_{-r}^{0} \int_{-r}^{0} \phi^T(\xi)R(\xi, \eta)\phi(\eta)d\xi d\eta + \int_{-r}^{0} \phi^T(\eta)S(\eta)\phi(\eta)d\eta,
\]
where
\[
P = P^T \in \mathbb{R}^{n \times n},
\]
\[
Q(\eta) \in \mathbb{R}^{m \times m},
\]
\[
R(\xi, \eta) = R^T(\xi, \eta) \in \mathbb{R}^{m \times m},
\]
\[
S(\eta) = S^T(\eta) \in \mathbb{S}^n,
\]
and \( \mathbb{S}^n \) represents the set of symmetric matrices, the superscript \( T \) denotes the transpose of a matrix or vector. 

Lemma 1. (Gu and Liu, 2009; Li, 2012) System (1)-(2) with \( \rho(D) < 1 \) is exponentially stable if there exists a quadratic Lyapunov-Krasovskii functional from (15)-(19), such that
\[
\epsilon \||\psi||^2 \leq V(\psi, \phi),
\]
for some \( \epsilon > 0 \), and its derivative along the system trajectory
\[
\dot{V}(\psi, \phi) \triangleq \limsup_{t \to 0^+} \frac{V(t, x(t, \psi, \phi), y_t(\psi, \phi)) - V(\psi, \phi)}{t}
\]
satisfies
\[
\dot{V}(\psi, \phi) \leq -\epsilon \||\psi||^2,
\]
where, \( \||\psi|| \) denotes 2-norm.
Define inner product on $Z$ given in (3),
\[
\left\langle \begin{bmatrix} \psi_1 \\ \phi_1 \end{bmatrix}, \begin{bmatrix} \psi_2 \\ \phi_2 \end{bmatrix} \right\rangle = r\psi_T^0 \psi_2 + \int_{-r}^0 \phi_T^0(s)\phi_2(ds).
\]
For matrix $P$ and matrix functions $Q, R, S$ that satisfy (16)-(19), we define the linear operator $\mathcal{P} : Z \rightarrow Z$
\[
\mathcal{P} \begin{bmatrix} \psi \\ \phi \end{bmatrix} = \begin{bmatrix} P\psi + \int_{-r}^0 Q(s)\phi(ds) \\ II \end{bmatrix},
\]
where
\[
\Pi = rQ^T(s) + \int_{-r}^0 R(s, \theta)\phi(\theta)d\theta + S(s)\phi(s).
\]

Obviously, $\mathcal{P}$ is a bounded and self-adjoint linear operator in view of (16)-(19), and the Lyapunov-Krasovskii functional may be expressed as
\[
V(\psi, \phi) = \left\langle \begin{bmatrix} \psi \\ \phi \end{bmatrix}, \mathcal{P} \begin{bmatrix} \psi \\ \phi \end{bmatrix} \right\rangle.
\]

As mentioned in Section 1, system (1)-(2) define a strongly $C_0$-semigroup $S : Z \rightarrow Z$ that satisfies (4). System (1)-(2) may also be written as an abstract differential equation (5) on $Z$. Let the domain of definition of $A$ be $X$. Then,
\[
X := \left\{ \begin{bmatrix} \psi \\ \phi \end{bmatrix} \in Z \mid \dot{\phi}(s) \in C, \phi(0) = C\psi + D\phi(-r) \right\},
\]
where $C$ represents the set of continuous functions. It is of interest in some cases to restrict $\mathcal{P}$ so that $X$ is invariant subspace of $\mathcal{P}$,
\[
\mathcal{P}X \subset X.
\]
The specific conditions for such a $\mathcal{P}$ to satisfy is given in the following.

**Lemma 2.** $\mathcal{P}$ satisfies (21) if and only if the following conditions are satisfied,
\[
\begin{align*}
    rQ^T(0) + S(0)C &= CP + rDQ^T(-r), \\
    R(0, s) &= CQ(s) + DR(-r, s), \\
    DS(-r) &= S(0)D.
\end{align*}
\]

**Proof.** Define $h(s) = rQ^T(s)\psi + \int_{-r}^0 R(s, \theta)\phi(\theta)d\theta + S(s)\phi(s)$ and $g = P\psi + \int_{-r}^0 Q(s)\phi(ds)$. Then, $\mathcal{P}X \subset X$ is equivalent to
\[
h(0) = Cg + Dh(-r),
\]
for arbitrary $\begin{bmatrix} \psi \\ \phi \end{bmatrix} \in X$, or
\[
\phi(0) = C\psi + D\phi(-r).
\]

Using (26), we have
\[
\begin{align*}
h(0) &= rQ^T(0)\psi + S(0)\phi(0) + \int_{-r}^0 R(0, \theta)\phi(\theta)d\theta \\
    &= rQ^T(0)\psi + S(0)C\psi + \int_{-r}^0 R(0, \theta)\phi(\theta)d\theta \\
    &\quad + S(0)D\phi(-r) \\
    &= (rQ^T(0) + S(0)C)\psi + \int_{-r}^0 R(0, \theta)\phi(\theta)d\theta \\
    &\quad + S(0)D\phi(-r)
\end{align*}
\]
and
\[
\begin{align*}
    \mathcal{P}^{-1} \begin{bmatrix} \psi \\ \phi \end{bmatrix}(s) &= \begin{bmatrix} \hat{P}\psi + \int_{-r}^0 \hat{Q}(\theta)\phi(\theta)d\theta \\
    r\hat{Q}^T(s)\psi + \hat{S}(s)\phi(s) + \int_{-r}^0 \hat{R}(s, \theta)\phi(\theta)d\theta \end{bmatrix},
\end{align*}
\]
where
\[
\begin{align*}
    \hat{R}(s, \theta) &= \hat{Z}^T(s)\hat{\Gamma}\hat{Z}(\theta), \\
    \hat{Q}(\theta) &= \hat{H}\hat{Z}(\theta), \\
    \hat{S}(s) &= S^{-1}(s), \\
    \hat{Z}(s) &= Z(s)S^{-1}(s), \\
    \hat{H} &= -P^{-1}HT, \\
    T &= (I + KT - rKH^TP_{-1}H)^{-1}, \\
    \hat{P} &= [I + rPH^TP_{-1}H]\hat{P}_{-1}, \\
    \hat{\Gamma} &= [rT^THTP_{-1}H - \Gamma](I + KT)^{-1}, \\
    K &= \int_{-r}^0 Z(s)S^{-1}(s)Z^T(s)ds,
\end{align*}
\]
and $I$ denotes the identity matrix with appropriate dimension.

**Proof.** Let the operator defined by the right hand side of (31) be denoted as $\hat{\mathcal{P}}$, then
\[
\hat{\mathcal{P}} \begin{bmatrix} \psi \\ \phi \end{bmatrix}(s) = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix},
\]
\[
= CP + Dh(-r) + \int_{-r}^0 CQ(s)\phi(ds) + rDQ^T(-r)\psi \\
\quad + \int_{-r}^0 DR(-r, s)\phi(ds) + DS(-r)\phi(-r) \\
\quad + \int_{-r}^0 (CQ(s) + DR(-r, s))\phi(ds)
\]
The right sides of (27)-(28) are equal for arbitrary $\psi$ and $\phi$ if and only if (22)-(24) are satisfied.

Obviously, the above is generalization of Theorem 3 in Peet (2016).

### 3. INVERSE OPERATOR

In this section, we will present an analytical expression for the inverse of the operator $\mathcal{P}$ when it is separable. Similar to Peet (2013), such an analytic expression for the inverse operator can be used to expedite the construction of the stabilizing controller in the controller synthesis problem.

**Definition 1:** An operator $\mathcal{P}$ defined in (20) is said to be separable if
\[
\begin{align*}
    R(s, \theta) &= Z^T(s)\Gamma Z(\theta), \\
    Q(s) &= HZ(s),
\end{align*}
\]
for some constant matrices $\Gamma = \Gamma^T$ and $H$, and column vector function $Z(s)$.

**Theorem 3.** Assume $\mathcal{P}$ in (20) is separable. Then, provided that all the inverse matrices below are well defined, its inverse may be expressed as
\[
\mathcal{P}^{-1} \begin{bmatrix} \psi \\ \phi \end{bmatrix}(s) = \begin{bmatrix} \hat{P}\psi + \int_{-r}^0 \hat{Q}(\theta)\phi(\theta)d\theta \\
    r\hat{Q}^T(s)\psi + \hat{S}(s)\phi(s) + \int_{-r}^0 \hat{R}(s, \theta)\phi(\theta)d\theta \end{bmatrix},
\]
\[
\hat{P} = [I + rPH^TP_{-1}H]\hat{P}_{-1},
\]
\[
\hat{\Gamma} = [rT^THTP_{-1}H - \Gamma](I + KT)^{-1},
\]
and $I$ denotes the identity matrix with appropriate dimension.

**Proof.** Let the operator defined by the right hand side of (31) be denoted as $\hat{\mathcal{P}}$, then
where

\[ A_1 = \int_{-r}^{0} \left( \dot{P}Q(\theta) + \dot{Q}(\theta) S(\theta) + \int_{-r}^{0} \dot{Q}(\xi) R(\xi, \theta) d\xi \right) \psi(\theta) d\theta + \left( \dot{P}P + \int_{-r}^{0} r\dot{Q}(\theta) Q^T(\theta) d\theta \right) \psi, \]

\[ A_2 = r \left( \dot{Q}^T(s)P + \dot{S}(s)Q^T(s) + \int_{-r}^{0} \dot{R}(s, \theta) Q^T(\theta) d\theta \right) \psi + \dot{S}(s)S(\theta) + \int_{-r}^{0} \left( r\dot{Q}^T(s)Q(\theta) + \dot{S}(s)R(s, \theta) + \dot{R}(s, \theta) S(\theta) + \int_{-r}^{0} \dot{R}(s, \xi) R(\xi, \theta) d\xi \right) \psi(\theta) d\theta. \]

Using (29)-(30) and (32)-(40), we obtain

\[ \dot{P}P + \int_{-r}^{0} \dot{Q}(\theta) Q^T(\theta) d\theta = \dot{P} + r\dot{H}KHT^T = [I + rP^{-1}HT(I + KT - rKHT P^{-1}H)^{-1}KH^T]^{-1} - P^{-1}HTKH^T]. \]

Thus, we have shown

\[ \hat{P} = \hat{P}, \]

where

\[ \hat{P} = \hat{P}. \]

\[ \hat{P}Q(\theta) + \dot{Q}(\theta) S(\theta) + \int_{-r}^{0} \dot{Q}(\xi) R(\xi, \theta) d\xi = 0. \]

Using (29)-(30) and (32)-(40), we obtain

\[ \dot{Q}^T(s)P + \dot{S}(s)Q^T(s) + \int_{-r}^{0} \dot{R}(s, \theta) Q^T(\theta) d\theta = 0, \]

\[ \dot{Z}(s)(\dot{H}^T P + H^T + \dot{K}KH^T) = [I + rP^{-1}HT(I + KT - rKHT P^{-1}H)^{-1}KH^T]^{-1} - P^{-1}HTKH^T - \dot{P}P + r\dot{H}KHT^T = 0. \]

From (41) and (42), we conclude that \( \hat{P} = \hat{P}. \)

\[ \textbf{Theorem 4.} \] If the separable operator \( \mathcal{P} \) satisfies \( \mathcal{P}X \in X, \) Then, \( \mathcal{P}^{-1}X \in X \) holds.

\[ \textbf{Proof.} \] Let the linear operator \( \mathcal{P} \) satisfy \( \mathcal{P}X \in X. \) By Lemma 2, this is equivalent to (22)-(24), from which, we obtain

\[ CP^{-1} = rS^{-1}(0)(DZT(-r) - ZT(0))H^TP^{-1} + S^{-1}(0)C, \]

\[ CH = (ZT(0) - DZT(-r))\Gamma, \]

\[ S^{-1}(0)D = DS^{-1}(-r). \]

Applying (43)-(45) to the operator \( \mathcal{P}^{-1} \) defined in (31), after tedious calculations, we can obtain the following equation,

\[ \dot{r}\dot{Q}^T(0)\psi + \dot{S}(0)\phi(0) + \int_{-r}^{0} \dot{R}(0, \theta) \phi(\theta) d\theta = C \left( \dot{P} + \int_{-r}^{0} \dot{Q}(\theta) \phi(\theta) d\theta \right) + D \left[ r\dot{Q}^T(-r)\psi + \dot{S}(-r)\phi(-r) + \int_{-r}^{0} \dot{R}(-r, \theta) \phi(\theta) d\theta \right], \]

from which, we conclude that \( \mathcal{P}^{-1}X \in X. \)

\section{4. CONTROLLER SYNTHESIS}

In this section, we consider a control system as follows

\[ \dot{x} = Ax + By(t - r) + Fu(t), \]

\[ y(t) = Cx(t) + Dy(t - r). \]

Define the infinitesimal generator \( \mathcal{A} \) as follows.

\[ \mathcal{A} \left[ \begin{array}{c} x \\ y_t \\ \end{array} \right] (s) = \left[ \begin{array}{c} Ax + By(t - r) \\ \frac{d}{ds} y_t(s) \end{array} \right]. \]

Likewise, we define the input operator \( \mathcal{F} : \mathbb{R}^3 \to X \) as

\[ (Fu)(t) := \begin{bmatrix} F \end{bmatrix} \begin{bmatrix} u(t) \\ y(t) \end{bmatrix}. \]

We define the controller synthesis problem as the search for matrices \( K_0, K_1 \) and matrix-valued function \( K_2(s) \) such that the System of Equations (46)-(47) is stable if

\[ u(t) = K \left[ \begin{array}{c} x \\ y_t \end{array} \right], \]

where we define \( K : X \to \mathbb{R}^q \) as

\[ K \left[ \begin{array}{c} x \\ y_t \end{array} \right] (s) = K_0x(t) + K_1y(t - r) + \int_{-r}^{0} K_2(s)y(t + s)ds. \]

Before we give the main result of the section, we briefly address SOS methods for enforcing joint positivity of coupled multiplier and integral operators using positive matrices. These methods have been developed in a series of papers, a summary of which can be found in the survey
paper Peet (2014). Specifically, for matrix-valued functions $M(s)$, $N(s, \theta)$, we say that
\[ \{M, N\} \in \Xi \]
if $M$ and $N$ satisfy the conditions of Theorem 8 in Peet (2014). The constraint $\{M, N\} \in \Xi$ can be cast as an LMI using SOSTOOLS as described in Peet (2014) and this constraint ensures that the operator $\mathcal{P}$, defined as
\[
\mathcal{P} \left[ \begin{array}{c} \psi \\ \phi \end{array} \right] = \left[ \begin{array}{c} M_{11} \psi + \int_{-r}^{0} M_{12}(s)\phi(s)ds \\ rM_{21}(s)\psi + \int_{-r}^{0} N(s, \theta)\phi(\theta)d\theta + M_{22}(s)\phi(s) \end{array} \right]
\]
is positive on $X$. Furthermore, we note that $\{M, N\} \in \Xi$ implies that $\mathcal{P}$ is separable and $P = \int M_{11}(ds)$ and $S = M_{22}$ are invertible. We now state the main result.

**Proposition 1:** Let $Z : \mathbb{R} \to \mathbb{R}^{q \times n}$ be an arbitrary continuously differentiable function. Suppose there exist matrices $M_0$, $M_1$, $P = P^T$, matrix-valued functions $M_2(s)$, $Q(s)$, $R(s, \theta)$, $S(s) = S^T(s) \in \mathbb{S}^{n}$, and scalar $\epsilon > 0$ such that (22)-(24) are satisfied and the following conditions hold
\[
\{T, R\} \in \Xi, \quad \{-U, -V\} \in \Xi,
\]
where
\[
T(s) = \left[ \begin{array}{ccc} P & rQ(s) & S(s) \\ rQ^T(s) & S(s) & 0 \\ S(s) & 0 & \hat{S}(s) \end{array} \right] - \epsilon I, \quad (50)
\]
\[
U(s) = \left[ \begin{array}{ccc} \Gamma + \epsilon I & BS(-r) + FM_1 + \frac{1}{\epsilon}C^T S(0)D & \Upsilon \\ * & \frac{1}{r}(S(-r) - D^T S(0)D) & 0 \\ * & * & \hat{S}(s) \end{array} \right], \quad (51)
\]
and $\epsilon$ denotes the corresponding symmetric part,
\[
\Gamma = AP + PA^T + r(BQ^T(-r) + Q(-r)B^T) + \frac{1}{\epsilon}C^T S(0)C + FM_0 + M_0^T F,
\]
\[
\Upsilon = r[Q(s) + BR(-r, s) + AQ(s) + FM_2(s)].
\]
Then System (46)-(47) is stabilizable with a controller of the form (48). Furthermore, let $\hat{P}$, $\hat{Q}$, $\hat{R}$ and $\hat{S}$ be as defined in Theorem 3. Then if
\[
u(t) = K_0 x(t) + K_1 y(t-r) + \int_{-r}^{0} K_2(s)y(t+s)ds,
\]
where
\[
K_0 = M_0 \hat{P} + rM_1 \hat{Q}^T(-r) + r \int_{-r}^{0} M_2(s)\hat{Q}^T(s)ds,
\]
\[
K_1 = M_1 \hat{S}(-r),
\]
\[
K_2(s) = M_0 \hat{Q}(s) + M_1 \hat{R}(-r, s) + M_2(s)\hat{S}(s) + \int_{-r}^{0} M_2(\theta)\hat{R}(\theta, s)d\theta,
\]
then the System (46)-(47) is stable.

**Proof.** Define
\[
\mathcal{P} \left[ \begin{array}{c} \psi \\ \phi \end{array} \right] = \left[ \begin{array}{c} P\psi + \int_{-r}^{0} Q(s)\phi(s)ds \\ rQ^T(s)\psi + \int_{-r}^{0} R(s, \theta)\phi(\theta)d\theta + S(s)\phi(s) \end{array} \right].
\]
Then as per Lemma 2, $\mathcal{P} = \mathcal{P}^*$, $\mathcal{P} : X \to X$ and $\mathcal{P} \geq \epsilon I$. Furthermore, $\mathcal{P}$ is bounded and as per Theorem 3, the inverse $\mathcal{P}^{-1}$ is defined as in (31) and is likewise bounded and coercive with $\mathcal{P}^{-1} \geq \epsilon I$. Furthermore, from Theorem 4, $\mathcal{P}^{-1} : X \to X$ and $\mathcal{P}^{-1} = \mathcal{P}^{-*}$. Now define the Lyapunov functional
\[
V = \left\langle \begin{array}{c} \psi \\ \phi(s) \end{array} \right| \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \right\rangle \geq \epsilon \left\| \phi(s) \right\|^2
\]
for $\left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \in X$. Since $\mathcal{P}^{-1} = \mathcal{P}^{-*}$,
\[
\left\langle \begin{array}{c} \psi \\ \phi(s) \end{array} \right| \mathcal{P}^{-1} A \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \right\rangle + \left\langle A \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] | \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \right\rangle
\]
\[
= \left\langle \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] | \mathcal{A} \mathcal{P} \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \right\rangle + \left\langle \mathcal{A} \mathcal{P} \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] | \mathcal{P}^{-1} \left[ \begin{array}{c} \psi \\ \phi(s) \end{array} \right] \right\rangle.
\]
Next, we note that if we define $\mathcal{K}$ as
\[
\mathcal{K} \left[ \begin{array}{c} x \\ y_1 \end{array} \right] = K_0 x(t) + K_1 y(t-r) + \int_{-r}^{0} K_2(s)y(t+s)ds,
\]
and $\mathcal{M}$ as
\[
\left[ \begin{array}{c} \mathcal{M} \\ \mathcal{M} \end{array} \right] \left[ \begin{array}{c} x \\ y_1 \end{array} \right] = M_0 x(t) + M_1 y(t-r) + \int_{-r}^{0} M_2(s)y(t+s)ds,
\]
then $\mathcal{K} := \mathcal{M} \mathcal{P}^{-1}$. We construct the controller
\[
\mathcal{M} \mathcal{P}^{-1} \left[ \begin{array}{c} x \\ y \end{array} \right] = M_0 \left( \hat{P} x + \int_{-r}^{0} \hat{Q}(\theta)y(\theta)d\theta \right) + M_1 \left( r\hat{Q}^T(-r)x + \hat{R}(-r, \theta)y(\theta)d\theta \right) + \int_{-r}^{0} M_2(s) \left( r\hat{Q}^T(s)x + \hat{S}(s)y(s) \right) ds + \int_{-r}^{0} \hat{R}(s, \theta)y(\theta)d\theta ds
\]
\[
= \left( M_0 \hat{P} + rM_1 \hat{Q}^T(-r) + r \int_{-r}^{0} M_2(s)\hat{Q}^T(s)ds \right) x + M_1 \hat{S}(-r)y(-r) + \int_{-r}^{0} M_2(s)\hat{Q}(s) + M_1 \hat{R}(-r, s) + M_2(s)\hat{S}(s) + \int_{-r}^{0} M_2(\theta)\hat{R}(\theta, s)d\theta \right) y(s)ds
\]
\[
= \mathcal{K} \left[ \begin{array}{c} x \\ y \end{array} \right].
\]
Now we define a new state \[ \frac{\hat{\phi}(s)}{\phi(s)} = \mathcal{P}^{-1} \frac{\psi(s)}{\phi(s)} \in X. \] Continuing, if \( u = K \begin{bmatrix} x \\ y \end{bmatrix} = K\mathcal{P}^{-1} \begin{bmatrix} x \\ y \end{bmatrix} \), then the closed-loop system is stable if \( \dot{V} < 0 \), where

\[
\dot{V} = \left\langle \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix}, \mathcal{A}\mathcal{P} \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right\rangle 
+ \left\langle \mathcal{A}\mathcal{P} \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix}, \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] \right\rangle 
+ \left\langle \mathcal{F}\mathcal{M} \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix}, \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] \right\rangle.
\]

To show that \( \dot{V} < 0 \), we examine \( \mathcal{A}\mathcal{P} \) and \( \mathcal{F}\mathcal{M} \) separately. First, we have

\[
\mathcal{A}\mathcal{P} \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} = \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right],
\]

where

\[
\Psi = \mathcal{A}\mathcal{P} \hat{\psi} + \int_{-r}^{0} \mathcal{A}Q(s)\hat{\phi}(s)ds + BrQ^T(-r)\hat{\psi}
+ BS(-r)\hat{\phi}(r) + \int_{-r}^{0} BR(-r, \theta)\hat{\phi}(\theta)d\theta,
\]

\[= rQ^T(r)\hat{\phi}(r) + \int_{-r}^{0} \mathcal{A}Q(s)\hat{\phi}(s)ds + r\mathcal{A}\mathcal{P} \mathcal{F}\mathcal{M} \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] \Omega \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] ds.
\]

Then,

\[
\left\langle \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix}, \mathcal{A}\mathcal{P} \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right\rangle = \int_{-r}^{0} \hat{\psi}^T \Psi ds + \int_{-r}^{0} \hat{\phi}^T(s)\Phi(s)ds
= r\mathcal{A}\mathcal{P} \mathcal{F}\mathcal{M} \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] \Omega \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] ds.
\]

Since \( \left[ \begin{bmatrix} \hat{\psi} \\ \phi(s) \end{bmatrix} \right] \in X \), we have \( \hat{\phi}(0) = C\hat{\psi} + D\hat{\phi}(-r) \). Then,

\[
\int_{0}^{t} \hat{\phi}^T(s)S(s)\hat{\phi}(s)ds
= \hat{\phi}^T(0)S(0)\hat{\phi}(0) - \hat{\phi}^T(-r)S(-r)\hat{\phi}(-r)
- \int_{-r}^{0} \hat{\phi}^T(s)S(s)\hat{\phi}(s)ds.
\]

For conditions (51)-(52), we have

\[
\dot{V} < 0.
\]

Therefore, the closed-loop System (46)-(47) is stable.

**Remark 5.** When \( F = 0 \) in System (46)-(47), we recover the standard delay-differential framework studied in Peet (2016) and Peet (2013):

\[
\dot{x}(t) = A_0x(t) + \sum_{i=1}^{t} A_i x(t - r_i)
= x(t) = \phi(t).
\]

The primary computational advantage of the differential-difference framework over control of System (46)-(47) is
that we can replace $A \in \mathbb{R}^{n \times n}$ with $BC$ where $B \in \mathbb{R}^{n \times m}$ and $C \in \mathbb{R}^{m \times n}$ and $m$ is typically strictly less than $n$. Because the dimension of the decision variables in the optimization problem defined in this paper scale as $n + 2m$ as opposed to $3n$ using the framework in Peet (2016) and Peet (2013), the complexity of the resulting algorithm is significantly reduced.

**Remark 6.** The feedback controller in (48) does not include delay in the input. However, the case of delay in the input can also be treated using a different form of $F$. This is left for future work.

**Remark 7.** Although not explicitly stated, in order to use SOS to enforce the conditions of Theorem 3 and Proposition 1, we choose our decision variables to be polynomial and use SOSTOOLS and the Positivstellensatz to enforce positivity/negativity on the interval $[-r, 0]$. This approach is described in more detail in Peet (2016) and Peet (2013).

In the following, we present a numerical example to illustrate the controller obtained from the conditions in Proposition 1. We consider the following system with a feedback controller as follows

$$\dot{x}(t) = \begin{bmatrix} 0 & 0.5 & 0 & 0 & 0 & 0 \\ -0.5 & -0.5 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0.1 & 1 & 0 & 0 \\ 0 & 0 & -2 & 0.2 & 0 & 0 \\ 0 & 0 & 0 & 1 & -2 & 0 \\ 0 & 0 & 0 & 0 & 0 & -0.9 \end{bmatrix} x(t)$$

$$+ \begin{bmatrix} 0.5 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix} y(t-r) + \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} u(t),$$

(56)

$$y(t) = \begin{bmatrix} -0.2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} x(t),$$

(57)

where $r = 1.6$. By using Proposition 1, together with the tools of MuPad, Matlab, SOSTOOLS and polynomials with degree 2, we obtain the controller

$$u(t) = \begin{bmatrix} -1.874 \\ 2.232 \\ -0.830 \\ 3.099 \\ 0.030 \\ -1.033 \end{bmatrix}^T x(t) + \begin{bmatrix} -0.239 \\ -0.343 \end{bmatrix}^T y(t-r)$$

$$+ \int_{-1.6}^0 K_2 y(t+s)ds,$$

(58)

where

$$K_2 = \begin{bmatrix} -0.246 + 0.221s + 0.122s^2 - 0.012s^3 - 0.032s^4 & 0.238 - 0.399s + 0.007s^2 + 0.037s^3 + 0.010s^4 \end{bmatrix}^T.$$

Using Controller (58) coupled with System (56)-(57) we simulate the closed-loop system, which is illustrated in Fig.1.

5. CONCLUSIONS

In this paper, we have obtained an analytic formulation for the inverse of jointly positive multiplier and integral operators as defined in Peet (2016). This formulation has the advantage that it eliminates the need for either individual positivity of the multiplier and integral operators or the need to use a series expansion to find the inverse. This inversion formula is applied to controller synthesis of coupled differential-difference equations. The use of the differential-difference formulation has the advantage that the size of the resulting decision variables is reduced, thereby allowing for control of systems with larger numbers of states. These methods are illustrated by designing a stabilizing controller for a system with 6 states and 2 delay channels.
