Preparation of Macrometallocycle and Selective Sensor for Copper Ion

Yingjie Liu¹, Zhixiang Zhao² & Qingxiang Liu²

Two bis-imidazolium salts 1,8-bis[(N-R-imidazoliumyl)acetylamino]naphthalene chloride (L¹H₄Cl₂: R = Et; L²H₄Cl₂: R = n-Bu), as well as their four NHC metal complexes [L¹H₄AgCl] (1), [L¹Ni] (2), [L²Ni] (3) and [L²H₄Hg(HgCl₄)] (4) have been synthesized. In each of the cationic moieties of complexes 1 or 4, there is a groove-like 14-membered macrometallocycle, and each macrometallocycle is consisted of one biscarbene ligand L¹H₄Cl₂ and one metal ion (silver(I) ion for 1 and mercury(II) ion for 4). Three 6-membered cycles are contained in each molecule of complexes 2 or 3. Additionally, the selective recognition of macrometallocycle 1 for Cu²⁺ was studied with the methods of fluorescence and ultraviolet spectroscopy, ¹H NMR titrations, MS and IR spectra. The experimental results display macrometallocycle 1 can discriminate Cu²⁺ from other cations effectively.

The detection of Cu²⁺ occupies an important position in host-guest chemistry because it plays a crucial part in chemistry, biology and environmental science¹–³. As a trace element in the body, copper are key components of hemocyanin and some enzymes. Ingesting excess or deficient Cu²⁺ will cause serious illness, such as Alzheimer’s and Wilson’s diseases, haematological manifestations and liver damage 4–12. Excess Cu²⁺ can also destroy the aquatic ecosystem, and disturb the nutrient absorption and transport of some plants 13. Among the detection of Cu²⁺, the fluorescent chemosensor is one of significant tools due to its high sensitivity and the simplicity of equipment 14–16. So far, a variety of types of fluorescent chemosensors for Cu²⁺ have been reported, such as organic small molecules and MOFs 17–23. Besides, Liu and co-workers reported a sensor based on porous conjugated polyelectrolyte, M···M interactions, M···X interactions and M···π interactions). Herein, we report the synthesis and characterization of new practical chemosensors are still desirable.

In the process of searching for suitable chemosensors for Cu²⁺, we focused on N-heterocyclic carbene (NHC) metal complexes because of their diverse structures, such as macrocycle 25–29, molecular rectangle 30–32 and groove 33,34. In a large number of complexes, cyclic NHC metal complexes have favorable recognition capability for metal ions 25–31, because this kind of host can capture effectively metal ions through several kinds of forces (electrostatic force, M···M interactions, M···X interactions and M···π interactions). Herein, we report the synthesis of bis-imidazolium salts 1,8-bis[(N-R-imidazoliumyl)acetylamino]naphthalene chloride (L¹H₄Cl₂: R = Et; L²H₄Cl₂: R = n-Bu), as well as the preparation and structure of four NHC complexes [L¹H₄AgCl] (1), [L¹Ni] (2), [L²Ni] (3) and [L²H₄Hg(HgCl₄)] (4). Additionally, we studied the selective recognition of macrometallocycle 1 for Cu²⁺ with the methods of fluorescence and ultraviolet spectroscopy, ¹H NMR titrations, MS and IR spectra.

Results and Discussion

Synthesis and characterization of L¹H₄Cl₂ and L²H₄Cl₂. As shown in Fig. 1, 1,8-diaminonaphthalene reacted with chloroacetyl chloride to give 1,8-di(2′-chloroacetylamino)naphthalene, which further reacted with N-R-imidazole (R = Et or n-Bu) to generate bis-imidazolium salts L¹H₄Cl₂ and L²H₄Cl₂. Precursors L¹H₄Cl₂ and L²H₄Cl₂ remain stable in the air, and can be dissolved in DMSO, dichloromethane and acetonitrile, but their solubility is poor in benzene, diethyl ether and petroleum ether. In the ¹H NMR spectra of L¹H₄Cl₂ and L²H₄Cl₂, the proton signals (NCHN) of imidazolium appear at δ = 9.47 and 9.50 ppm, and these values are analogous to those of known imidazolium compounds 35,40–46.

Synthesis and general characterization of complexes 1–4. The synthesis of NHC silver(I) complex [L¹H₄AgCl] (1) was accomplished via the reaction of L¹H₄Cl₂ with Ag₂O in CH₃CN/DMSO (Fig. 2). The reactions of L¹H₄Cl₂ or L²H₄Cl₂ with NiCl₂ in the presence of K₂CO₃ in CH₃CN/DMSO afforded NHC nickel(II)

Correspondence and requests for materials should be addressed to Q.L. (email: tjnulqx@163.com)
complexes [L\textsuperscript{1}Ni] (2) and [L\textsuperscript{3}Ni] (3). The reaction of L\textsuperscript{1}H\textsubscript{4}Cl\textsubscript{2} with HgCl\textsubscript{2} in the presence of KO\textsuperscript{t}Bu in CH\textsubscript{3}CN/DMSO gave NHC mercury(II) complex L\textsuperscript{4}H\textsubscript{4}Cl\textsubscript{2} (4).

The crystals of complexes 1–4 were obtained via slow adding Et\textsubscript{2}O to their solutions. Complexes 1–4 can be dissolved in DMSO and CH\textsubscript{3}CN, but they are scarce soluble in benzene, diethyl ether and petroleum ether.

solution of complex 1 is slightly light-sensitive. The proton signals (NCHN) of imidazolium disappear in the \(^{1}H\) NMR spectra of 1–4 due to the introduction of metals, and other proton signals are analogous to \(L\)\(^{1}H_{4}\)·Cl\(_{2}\) or \(L^{2}H_{4}\)·Cl\(_{2}\). In the \(^{13}C\) NMR spectra of 1, no carbene carbon signal is found, and this phenomenon may be the
fluxional behavior of the NHC silver(I) complexes\textsuperscript{47–49}. The carbene carbon signals of 2–4 are observed at 175.0–176.8 ppm, which are consistent with other NHC metal complexes in literatures\textsuperscript{50–60}.  

**Structure of complexes 1–4.** In complexes 1–4 (Figs 3–6), the N-C-N angles are between 103.5(1)° and 106.3(5)°, and these values are consistent with those of literatures\textsuperscript{47–49,61}. One 14-membered macrometallocycle is contained in each of the molecules of complexes 1 or 4. By contrast, three 6-membered cycles in each molecule of 2 or 3 are observed. In the same ligand for 1–4, the naphthalene plane and two imidazole planes form the dihedral angles of 51.5(5)°–75.9(8)° (Table S1 in Supporting Information). Two imidazole planes in the same NHC-metal-NHC unit form the dihedral angles of 9.6(5)°–14.2(4)° for 1 and 4. In complexes 2 and 3, the dihedral angles formed by two imidazole planes are in the range of 74.9(1)–83.4(3)°.

In complex 1, the arrangement of C(3)-Ag(1)-C(20) is almost linear with the angle of 175.3(3)°, and the distances of Ag(1)-C(3) and Ag(1)-C(20) are 2.074(8) Å and 2.100(8) Å. Both are comparable with those of known NHC Ag(I) complexes\textsuperscript{47–49}.

In complexes 2 or 3, two acetylamino groups (-CONH-) and two imidazolium moieties of precursors L\textsubscript{1}H\textsubscript{4}Cl\textsubscript{2} or L\textsubscript{2}H\textsubscript{4}Cl\textsubscript{2} are deprotonated in the presence of K\textsubscript{2}CO\textsubscript{3}. As a result, Ni(II) ion is coordinated to two carbene atoms and two nitrogen atoms to adopt a quadrilateral geometry with slight distortion. The bond distances of C-Ni and N-Ni are 1.858(5)–1.900(2) Å and 1.918(1)–1.933(4) Å, respectively. The bond angles of C-Ni-C, N-Ni-N and C-Ni-N are 91.2(2)–97.9(1)°, 87.0(8)–94.6(2)° and 84.4(9)–169.9(9)°, respectively. Similar values were also reported in other literatures about NHC Ni(II) complexes\textsuperscript{61}.

Both of Hg(1) and Hg(2) in complex 4 are tetra-coordinated. The distances of Hg(1)-C(5) and Hg(1)-C(20) are 2.073(6) Å and 2.081(7) Å, and the bond angle of C(5)-Hg(1)-C(20) is 168.6(2)°. The distances of Hg(2)-Cl(2) (2.418(2)–2.557(1) Å) are shorter than that of Hg(1)-Cl(1) (2.880(1) Å). A distorted Hg\textsubscript{2}Cl\textsubscript{4} quadrangular arrangement is formed by Hg(1), Cl(1), Hg(2) and Cl(2), in which the dihedral angle between the Cl(1)-Hg(1)-Cl(2) plane and the Cl(1)-Hg(2)-Cl(2) plane is 30.5(8)°. The Hg···Hg separation of 3.815(5) Å suggests the nonexistence of metal-metal interactions between both Hg(II) ions (van der Waals Radii of mercury = 1.70 Å)\textsuperscript{62,63}.

**Recognition of Cu\textsuperscript{2+} using 1 as a chemosensor.** The screening experiments of complexes 1–4 for some cations (Li\textsuperscript{+}, Na\textsuperscript{+}, K\textsuperscript{+}, NH\textsubscript{4}\textsuperscript{+}, Ag\textsuperscript{+}, Ca\textsuperscript{2+}, Co\textsuperscript{2+}, Ni\textsuperscript{2+}, Cu\textsuperscript{2+}, Zn\textsuperscript{2+}, Cd\textsuperscript{2+}, Cr\textsuperscript{3+}, Al\textsuperscript{3+}, Pb\textsuperscript{2+} and Hg\textsuperscript{2+}), and their anions (NO\textsubscript{3}\textsuperscript{−}, CN\textsuperscript{−}, Cl\textsuperscript{−}, Br\textsuperscript{−}, I\textsuperscript{−}) via fluorescence spectroscopy in CH\textsubscript{3}CN at 25 °C were carried out. The fluorescence intensities of complexes 2–4 didn’t change after adding cations. However, the fluorescence emission of complex 1 decreased remarkably after adding Cu\textsuperscript{2+}, and other cations did not have similar phenomenon. Therefore, complex 1 was selected as a chemosensor to process recognition investigation of cations.

To evaluate the response time of complex 1 to Cu\textsuperscript{2+}, the time-dependent plot was measured (Fig. 7). The results showed that the interactions between Cu\textsuperscript{2+} and 1 can cause fluorescence quenching, in which fluorescence intensity quickly reduced within 6 minutes, and then the tendency slowed down. The fluorescence quantum yields (\(\Phi\)) of L\textsubscript{1}H\textsubscript{4}Cl\textsubscript{2} and complex 1 using 1-aminonaphthalene as fluorescence standard (\(\Phi = 0.39\)) were measured\textsuperscript{64}. The fluorescence quantum yields of L\textsubscript{1}H\textsubscript{4}Cl\textsubscript{2} and complex 1 were determined to be 0.16 and 0.21, and the latter was higher than the former. It may be originated to the incorporation of metal-ligand coordination interactions\textsuperscript{65,66}.

As shown in Fig. 8, complex 1 showed a fluorescence emission band at ca. 415 nm, which originated from conjugated bis(acetylamino)-naphthalene (\(\lambda_{ex} = 330\ nm\)). When 10 equiv. of Li\textsuperscript{+}, Na\textsuperscript{+}, K\textsuperscript{+}, NH\textsubscript{4}\textsuperscript{+}, Ag\textsuperscript{+}, Ca\textsuperscript{2+}, Co\textsuperscript{2+}, Ni\textsuperscript{2+}, Zn\textsuperscript{2+}, Cd\textsuperscript{2+}, Cr\textsuperscript{3+}, Al\textsuperscript{3+}, Pb\textsuperscript{2+} and Hg\textsuperscript{2+} were added, the fluorescence intensity of 1 had no observable change. However, the significant fluorescence quenching of 1 was observed after adding 10 equiv. of Cu\textsuperscript{2+}. In UV/vis experiment, upon addition of Cu\textsuperscript{2+} to the solution of 1, the absorption of 1 at ca. 250–350 nm increased remarkably, but other cations had no similar influence on the absorption of 1 (Fig. S1 in the Supporting Information). The experiment results showed that 1 can discriminate Cu\textsuperscript{2+} from other cations effectively.

---

Figure 10. The Job’s plot of 1 toward Cu\textsuperscript{2+} at 214 nm. \(\chi\) is the molar fraction of 1. It illustrates the host-guest fluorescence quenching occurs in 1:1 complexation.
In the fluorescence titration experiments (Fig. 9), upon the titration of Cu$^{2+}$ into solutions of 1 in CH$_3$CN at 25 °C, the fluorescence intensities of 1 at ca. 415 nm decreased gradually. In the inset of Fig. 9, the fluorescence intensities of 1 went down quickly in the ratios of $C_{Cu^{2+}}/C_{1}$ being 0 to 10:1. When the ratio ascended to 20:1, the quenching rate slowed down. Finally, fluorescence intensities remained unchanged even though more Cu$^{2+}$ was added. The quenching behaviors of Cu$^{2+}$ on the fluorescence of 1 were found to follow a conventional Stern-Volmer relationship 67,68 (equation (1)).

$$\frac{F_0}{F} = 1 + K_{SV}C_{Cu^{2+}}$$

where $F_0$ and $F$ are the fluorescence intensities of 1 in the absence and presence of Cu$^{2+}$, and $C_{Cu^{2+}}$ is the concentration of Cu$^{2+}$. The equation reveals that $F_0/F$ increases in direct proportion to the increasing concentration of Cu$^{2+}$, and the Stern-Volmer constant $K_{SV}$ defines the quenching efficiency of Cu$^{2+}$.

The $K_{SV}$ value for 1-Cu$^{2+}$ was calculated as $5.68 \times 10^5$ M$^{-1}$ (R = 0.9999) by using the equation (1) (Fig. S2). As shown in Fig. S3, the detection limit was estimated to be $1.5 \times 10^{-7}$ mol/L. To further confirm the complexation stoichiometry between 1 and Cu$^{2+}$, a Job's plot analysis at 214 nm was carried out (Fig. 10)$^{62,63}$. The $\Delta A$ values for 1-Cu$^{2+}$ reached a maximum when molar fractions ($\chi$) of 1 was 0.5, and it indicated stoichiometric ratio was 1:1. Where total concentration was a constant, and $\Delta A$ was the discrepancy of the absorption bands.

**Figure 11.** Partial $^1$H NMR spectra in DMSO-$d_6$. (i) 1; (ii) 1 and 0.25 equiv. of Cu$^{2+}$; (iii) 1 and 0.5 equiv. of Cu$^{2+}$; (vi) 1 and 1 equiv. of Cu$^{2+}$; (v) 1 and 1.5 equiv. of Cu$^{2+}$; (vi) 1 and 2 equiv. of Cu$^{2+}$.

**Figure 12.** The interactions of 1 with Cu$^{2+}$. 

In the fluorescence titration experiments (Fig. 9), upon the titration of Cu$^{2+}$ into solutions of 1 in CH$_3$CN at 25 °C, the fluorescence intensities of 1 at ca. 415 nm decreased gradually. In the inset of Fig. 9, the fluorescence intensities of 1 went down quickly in the ratios of $C_{Cu^{2+}}/C_{1}$ being 0 to 10:1. When the ratio ascended to 20:1, the quenching rate slowed down. Finally, fluorescence intensities remained unchanged even though more Cu$^{2+}$ was added. The quenching behaviors of Cu$^{2+}$ on the fluorescence of 1 were found to follow a conventional Stern-Volmer relationship 67,68 (equation (1)).

$$\frac{F_0}{F} = 1 + K_{SV}C_{Cu^{2+}}$$

where $F_0$ and $F$ are the fluorescence intensities of 1 in the absence and presence of Cu$^{2+}$, and $C_{Cu^{2+}}$ is the concentration of Cu$^{2+}$. The equation reveals that $F_0/F$ increases in direct proportion to the increasing concentration of Cu$^{2+}$, and the Stern-Volmer constant $K_{SV}$ defines the quenching efficiency of Cu$^{2+}$.

The $K_{SV}$ value for 1-Cu$^{2+}$ was calculated as $5.68 \times 10^5$ M$^{-1}$ (R = 0.9999) by using the equation (1) (Fig. S2). As shown in Fig. S3, the detection limit was estimated to be $1.5 \times 10^{-7}$ mol/L. To further confirm the complexation stoichiometry between 1 and Cu$^{2+}$, a Job's plot analysis at 214 nm was carried out (Fig. 10)$^{62,63}$. The $\Delta A$ values for 1-Cu$^{2+}$ reached a maximum when molar fractions ($\chi$) of 1 was 0.5, and it indicated stoichiometric ratio was 1:1. Where total concentration was a constant, and $\Delta A$ was the discrepancy of the absorption bands.
To test the ability to resist interference of other cations, the competition experiments were conducted (Fig. S4), where 1 (2.0 × 10−4 mol/L) was mixed with 5 equiv. of Li+, Na+, K+, NH4+, Ag+, Ca2+, Ba2+, Ni2+, Zn2+, Cd2+, Cr(III), Al3+, Pb2+ or Hg22+, and then 5 equiv. of Cu2+ was added. The presence of other cations did not cause any significant changes in the emission of 1-Cu2+.

Analogous to Fig. 8, the decrease of fluorescence intensities of 1 were also observed after the addition of other copper(II) salts (1.0 × 10−3 mol/L) with different counter anions (Br−, SO42−, OAc−, Cl−, NO3− and CO32−) (Fig. S5). Thus, the different anions did not obviously influence on the binding between 1 and Cu2+. Reversible binding of 1 with Cu2+ was also carried out (Fig. S6). The addition of 10 equiv. of EDTA to a mixture of 1 (2.0 × 10−4 mol/L) and Cu2+ (20 × 10−8 mol/L) resulted in the increase of fluorescence intensity at 415 nm, and the fluorescence intensity was approximately equal to that of 1, which signified the regeneration of the free 1. The fluorescence intensity decreased upon the addition of Cu2+ again. This result showed that 1 was a good chemosensor for Cu2+ with admirable reversibility and regeneration capacity.

**Table 1.** Summary of crystallographic data for 1–4. a \( GOF = \frac{\|F_o\| - \|F_c\|}{\|F_c\|} \), \( R \) and \( wR \) are the goodness-of-fit on F2, \( R_1 \) and \( wR_1 \) are the goodness-of-fit indices for 1–4, respectively.

**Interactions of 1 with Cu2+**. The potential binding sites of 1 for Cu2+ may be oxygen atoms, nitrogen atoms and \( \pi \) systems (including O−Cu2+, N−Cu2+ interactions and \( \pi \)−Cu2+ interactions). To get detailed information on how 1 bound with Cu2+, we studied the data of 1H NMR titrations (\( CD_2Cl_2/C_6 \)) from 0 to 2.0 equiv.) in DMSO-\( d_6 \) (Fig. 11). Upon the addition of 1 equiv. of Cu2+, the proton signal on NH (Hd) had a large downfield shift by 0.92 ppm (Fig. 11(iv)), and the proton signals of He and Hf on naphthalene ring also shifted to downfield (ca. 0.27 ppm), which may be attributed to electron-withdrawing effect of Cu2+ due to Cu2+−N interactions (Fig. 12). The proton signal of Hc on CH2 attached to C−O shifted to downfield (ca. 0.25 ppm), which may be attributed to electron-withdrawing effect of Cu2+ due to Cu2+−O interactions. More equivalents of Cu2+ did not cause further change of chemical shifts of Hc−Hf (Fig. 11(vii)), which showed the combination ratio between 1 and Cu2+ was 1:1.

Additional evidence for the combination ratio between 1 and Cu2+ was obtained through high-resolution mass spectra of 1/Cu2+ (Fig. S7). The observation of m/z (318.3) for (1-Cu2+)/2 further confirmed the formation of a 1:1 complex. This finding agreed with the result of Job’s plot (Fig. 10). The IR spectra of 1 and 1-Cu2+ were measured for more information about how 1 bound with Cu2+. In Fig. S8, we found that several absorption bands...
have changed after adding Cu²⁺. The ν₃(C=N) varied from 1660 cm⁻¹ to 1683 cm⁻¹, ν₁(N-H) varied from 3378 cm⁻¹ to 3382 cm⁻¹, and Δν₂(N-H) varied from 1617 cm⁻¹ to 1629 cm⁻¹, respectively.

By analyzing the structure of I and above experiment results, we can conclude that I bound with Cu²⁺ mainly through Cu²⁺–O and Cu²⁺–N interactions. Once complex 1–Cu²⁺ was formed, the photo-induced electron transfer (PET) process from the imidazole rings to naphthalene ring was switched on and it led to the quench of fluorescence emission of I⁶⁹,⁷⁰. We tried to cultivate the single crystal of 1–Cu²⁺, but unsuccessful.

Conclusion
In conclusion, we prepared and characterized two bis-imidazolium salts L¹H₂Cl₂ and L²H₂Cl₂, as well as their four NHC metal complexes 1–4. In each molecule of 1 or 4, one 14-membered groove-like macrometallocycle was contained. Additionally, the selective recognition of macrometallocycle 1 for Cu²⁺ was studied with the methods of fluorescence and ultraviolet spectroscopy, 1H NMR titrations, MS and IR spectra. The experimental results displayed macrometallocycle 1 can distinguish Cu²⁺ from other cations effectively. Kₓ, value of 5.68 × 10⁵ M⁻¹ for 1–Cu²⁺ based on a 1:1 association equation analysis was obtained through fluorescence titrations. The detection limit was calculated as 1.5 × 10⁻⁷ mol/L, which indicated that 1 is sensitive for Cu²⁺. In literatures, some peptide sensors for Cu²⁺ were reported⁷¹,⁷², and their association constants and detection limits were in the ranges of 10³–10⁵ M⁻¹ and 10⁻¹–10⁻⁸ mol/L. Compared with these sensors, sensor 1 showed similar binding ability and good sensitivity to Cu²⁺. Further investigation for new NHC metal complexes from L¹H₂Cl₂, L²H₂Cl₂ and similar to precursors are still under way.

Experimental Section
General procedures. N-ethyl-imidazole and N-t-butyl-imidazole were prepared according to the methods of literature reported⁷⁷,⁷⁸. Schlenk techniques were used in all manipulations. All the reagents for synthesis and analyses were of analytical grade and used without further purification. Melting points were determined with a Boetius Block apparatus. §H and 13C NMR spectra were recorded on a Varian Mercury Vx 400 spectrometer at 400 MHz and 100 MHz, respectively. Chemical shifts, δ, are reported in ppm relative to the internal standard TMS for both §H and 13C NMR. J values are given in Hz. Elemental analyses were measured using a Perkin-Elmer 2400 C Elemental Analyzer. The fluorescence spectra were performed using a Cary Eclipse fluorescence
spectrophotometer. UV-vis spectra were recorded on a JASCO-V570 spectrometer. EI mass spectra were recorded on a VG ZAB-HS mass spectrometer (VG, U.K.). IR spectra (KBr) were taken on a Bruker Equinox 55 spectrometer.

### Synthesis of 1,8-bis(2′-chlooroacetyl)diaminonaphthalene. A suspension of 1,8-diaminonaphthalene (10.000 g, 63.2 mmol) and triethylamine (21.0 mL, 151.6 mmol) in CH₂Cl₂ (120 mL) was stirred for 30 min at 0 °C. Then chloroacetyl chloride (11.4 mL, 151.7 mmol) was dropwise added to the suspension above and stirred continually for 3 h at ambient temperature. The mixture was filtered and washed by water to afford 1,8-bis(2′-chloroacetyl)diaminonaphthalene as a yellow powder. Yield: 15.731 g (80%). M.p.: 265–267 °C. ²H NMR (400 MHz, DMSO-d₆): δ 4.36 (s, 4H, CH₂), 7.52 (t, J = 3.4 Hz, 6H, PhH), 7.90 (t, J = 4.6 Hz, 2H, PhH), 10.10 (s, 2H, NH). ¹³C NMR (100 MHz, DMSO-d₆): δ 43.8 (CH₃), 126.0 (PhC), 127.8 (PhC), 132.18 (PhC), 135.9 (PhC), 165.6 (C=O).

### Preparation of 1,8-bis[2′-(N-ethylimidazolium)acylamino]naphthalene chloride (L₁H₄Cl₂). A solution of N-ethyl-imidazole (1.538 g, 16.0 mmol) and 1,8-bis(2′-chlooroacetyl)naphthalene (2.000 g, 6.4 mmol) in DMF (150 mL) was heated to reflux for 7 days with stirring, and precipitated a black powder. The precipitate was collected by filtration and washed with a small portion of DMF to give 1,8-bis[2′-(N-ethylimidazolium)acylamino]naphthalene chloride. Yield: 1.480 g (48%). M.p.: 260–261 °C. Anal. Calcd for C₉₂H₁₄₈N₂O₈Cl₂: C, 50.23; H, 4.56; N, 16.69%. Found: C, 50.42; H, 4.56; N, 16.86%. ¹H NMR (400 MHz, DMSO-d₆): δ 1.48 (t, J = 7.2 Hz, 6H, CH₃), 4.32 (m, 4H, CH₂), 5.50 (s, 4H, CH₂), 7.59 (s, 2H, PhH), 7.92 (t, J = 15.6 Hz, 4H, PhH), 9.47 (s, 2H, 2-imH), 11.07 (s, 2H, NH). ¹³C NMR (100 MHz, DMSO-d₆): δ 15.6 (CH₃), 44.7 (CH₂), 52.1 (CH₃), 121.6 (PhC), 124.7 (PhC), 125.8 (PhC), 126.8 (PhC), 127.9 (PhC), 131.4 (PhC), 136.0 (PhC), 137.7 (PhC), 164.9 (C=O) (imi = imidazolium).

### Preparation of 1,8-bis[2′-(N-butyliimidazolium)acetylamino]naphthalene chloride (L₁H₄Cl₂). L₁H₄Cl₂ was prepared according to the methods of L₁H₄AgCl (1). The mixture of L₁H₄Cl₂ (0.100 g, 0.2 mmol) and Ag(OH)₂ (0.046 g, 0.2 mmol) in DMSO (2.5 mL) and CH₂CN (12.5 mL) was heated to reflux for 24 h with stirring. After filtration, the solvent was evaporated to 5 mL, and the pale yellow powder of L₁H₄Cl₂ was obtained after adding 5 mL of diethyl ether. Yield: 0.040 g (36%). M.p.: 192–194 °C. Anal. Calcd for C₉₂H₁₄₈N₂O₈Cl₂: C, 50.23; H, 4.56; N, 14.64%. Found: C, 50.44; H, 4.42; N, 14.52%. ¹H NMR (400 MHz, DMSO-d₆): δ 1.43 (t, J = 17.5 Hz, 6H, CH₃), 4.20 (q, 4H, CH₂), 5.06 (s, 4H, CH₂), 7.29 (m, 4H, PhH), 7.60 (d, J = 88 Hz, 4H, PhH), 8.34 (s, 2H, PhH), 9.29 (s, 2H, NH). ¹³C NMR (100 MHz, DMSO-d₆): δ 17.3 (CH₃), 46.2 (CH₂), 121.3 (CH₂), 121.4 (PhC), 124.1 (PhC), 125.5 (PhC), 135.9 (PhC), 166.3 (C=O).

### Preparation of [L₁H₄AgCl] (1). NiCl₂ (0.052 g, 0.4 mmol) was mixed with L₁H₄Cl₂ (0.100 g, 0.2 mmol) and K₂CO₃ (0.138 g, 1.0 mmol) in DMSO (2.5 mL) and CH₂CN (12.5 mL), and the reaction kept going for 24 h at 60 °C with stirring. After filtration, the solvent was evaporated to 5 mL, and the pale yellow powder of 1 was obtained after adding 5 mL of diethyl ether. Yield: 0.040 g (30%). M.p.: >230 °C. Anal. Calcd for C₉₂H₁₄₈N₂O₈Cl₂·C₂H₅OH: C, 59.16; H, 4.96; N, 17.25%. Found: C, 59.32; H, 4.87; N, 17.43%. ¹H NMR (400 MHz, DMSO-d₆): δ 1.06 (t, J = 7.2 Hz, 6H, CH₃), 3.41 (q, J = 6.9 Hz, 4H, CH₂), 4.50 (t, J = 3.2 Hz, 4H, CH₂), 6.70 (s, 2H, PhH), 7.11 (t, J = 7.6 Hz, 2H, PhH), 7.28 (d, J = 2.0 Hz, 2H, PhH), 7.40 (d, J = 3.0 Hz, 2H, PhH), 7.55 (d, J = 0.5 Hz, 2H, PhH). ¹³C NMR (100 MHz, DMSO-d₆): δ 15.6 (CH₃), 44.5 (CH₂), 65.3 (CH₃), 121.5 (PhC), 122.2 (PhC), 124.5 (PhC), 135.4 (PhC), 166.6 (C=O), 175.0 (2-im-H).
Fluorescence titrations. The stock solution (1.0 × 10⁻⁴ M) of the host was prepared and diluted to the suitable concentration with CH₃CN. The stock solutions (1.0 × 10⁻³ M or 1.0 × 10⁻⁴ M) of guest were prepared and diluted in the same solvent. Test solutions were prepared through placing 0.2 mL of host stock solution into a 10 mL volumetric flask, and the appropriate amount of the stock solutions (1.0 × 10⁻³ M or 1.0 × 10⁻⁴ M) of guest were added with a microsyringe. The mixture solutions were diluted to 10 mL with CH₃CN to prepare test solutions. The concentrations of guest in the test solutions were from 0 to 24.0 × 10⁻⁶ M, and the concentration of host stayed the same (2.0 × 10⁻⁴ M). The test solutions were kept at 25 °C for 8–10 minutes, and then fluorescence spectra were recorded with the excitation wavelength at 330 nm, and the excitation and emission slits are 5 nm and 5 nm. Statistical analysis of the data was carried out using Origin 8.0. CH₃CN used in the titrations was freshly distilled.

Quantum yields. Fluorescence quantum yields (Φ) of L¹H₁Cl₁ and complex I were determined by using 1-aminonaphthalene (Φ = 0.39) in CH₃CN as the standard compound. Fluorescence quantum yields could be calculated according to the equation (2) below64.

\[ Φ_U = \Phi_D(A_D/A_U)(F_U/F_D)(n_D/n_U)^2 \]

where Φ_D, A_D, and F_D are the quantum yield, the absorbance and the emission intensity for L¹H₁Cl₁ or complex I. Φ_U, A_U and F_U are the quantum yield, the absorbance and the emission intensity for 1-aminonaphthalene. n_D and n_U are the average refractive index of the sample solution (n_U = n_D = n_water).

Method for Job’s plot. The stock solution (1.0 × 10⁻⁴ M) of the host was prepared and diluted to the suitable concentration with CH₃CN. The stock solutions (1.0 × 10⁻³ M or 1.0 × 10⁻⁴ M) of guest were prepared and diluted in the same solvent. The molar fractions of host and guest in the test solutions were from 1 to 0 and 0 to 1, respectively. The total concentration is 4.0 × 10⁻⁴ M and different amounts of host and guest solutions were placed into a 10 mL volumetric flask using a microsyringe, and then diluted to 10 mL. The test solutions were kept at 25 °C for 8–10 minutes, and then absorption spectra were measured. Statistical analysis of the data was carried out using Origin 8.0.

X-Ray data collection and structure determinations. A Bruker Apex II CCD diffractometer were used for the collection of diffraction data of 1–4⁶⁸. The structure was solved with the SHELXS program⁷⁹. Figures 1–4 were formed via employing Crystal-Maker⁸⁰. Other details for structural analysis and crystallographic data was listed in Tables 1 and 2.
