Abstract. The production of pro-inflammatory cytokines and chemokines is increased during inflammatory bowel disease (IBD). Previously, it was demonstrated that brain derived neurotrophic factor (BDNF) expression is increased in experimental models of colitis. BDNF is partially responsible for the structural and functional changes that take place during IBD. However, the exact mechanisms underlying the upregulation of BDNF during gut inflammation are unknown. The aim of the present study was to determine the effects of direct treatment of smooth muscle cells with inflammatory cytokines on the synthesis and secretion of BDNF. BDNF expression and secretion levels were measured using ELISA kits on tissue lysates and on incubation media used to culture the rat colon smooth muscle tissues treated for 24 h with either tumor necrosis factor (TNF)-α or interleukin (IL)-1β. Compared with the control tissue samples, treatment with TNF-α and IL-1β resulted in a significant increase in the protein expression levels of BDNF in the incubated smooth muscle tissue. TNF-α and IL-1β also stimulated the secretion of BDNF. Chelation of intracellular Ca²⁺ with BABTA-AM prevented the result in the significant increase in the protein expression levels of BDNF in the incubated smooth muscle tissue. Furthermore, inhibition of protein kinase A (PKA) significantly reduced BDNF expression levels when treated with cytokines but not secretion. In conclusion, proinflammatory cytokines that are upregulated during IBD, directly stimulated BDNF expression and secretion in a Ca²⁺ dependent manner. Considering the ability of BDNF to enhance smooth muscle contraction and pain sensation, this autocrine loop may partially explain the characteristic hypercontractility and hypersensitivity associated with IBD.

Introduction

Ulcerative colitis (UC) and Crohn's disease (CD), collectively known as inflammatory bowel disease (IBD), are chronic, relapsing, immune-mediated disorders (1). CD is characterized by patchy granulomatous inflammation that may affect any part of the gastrointestinal tract, from the mouth to the anus (2). UC is characterized by a continuous pattern of inflammation that is restricted to the colon (3). The prevalence of IBD has rapidly increased in Europe and North America in the second half of the twentieth century and is becoming more common in the rest of the world, as different countries adopt a Western based diet and lifestyle (4).

The pathogenesis underlying IBD is complex and results from the interaction of environmental factors, genetic variations and intestinal microbiota with the innate and adaptive immune responses (5). Altered immune responses are considered the cornerstone of the pathogenesis underlying IBD (5). For example, in both forms of IBD, the numbers of macrophages and dendritic cells in the lamina propria increase and attain an activated phenotype (5). Furthermore, the production of pro-inflammatory cytokines and chemokines is also enhanced (5). The analysis of the inflamed mucosa from patients with IBD shows an increase in the expression of several cytokines, such as interleukin (IL)-1, IL-6, IL-8 and tumor necrosis factor (TNF)-α (5). These cytokines are hypothesized to subsequently direct the development of an adaptive immune response which is primarily mediated by T and B lymphocytes (6). The cumulative effect of the above processes eventually leads to IBD.

The production of cytokines serves a central role in the pathogenesis of IBD. Another hallmark of IBD is the dysmotility of the muscular layers of the bowel (7). The specific mechanism underlying the IBD-mediated changes in contractility are currently unknown but may be directly or indirectly associated with the increased production of cytokines. The neurotrophic factor, brain derived neurotrophic factor (BDNF), has been shown to be secreted by smooth muscle cells of the rat colon in a dextran sodium sulphate induced colitis model (8), which enhances the cholinergic contraction of the smooth muscle cells of the colon (9). Taken together, it is hypothesized that cytokines
produced from the inflammation of the bowel observed in IBD, may directly stimulate the expression of BDNF in the smooth muscle cells of the colon. Secreted BDNF acts in an autocrine manner and affects the contractility of the smooth muscle cells themselves. These observations demonstrate a tentative link between the increased production of inflammatory cytokines in bowel tissues and the ensuing changes in contractility. To support this hypothesis, the aim of the present study was to test the hypothesis that direct treatment of colon smooth muscle cells with inflammatory cytokines increased the synthesis and secretion of BDNF.

Materials and methods

Animal experiments. All experiments were performed in accordance with the Institutional Animal Care and Use Committee at Jordan University of Science and Technology (approval no. 2019/0023). Male adult Sprague-Dawley rats, weighing 150-200 g, were maintained at the University animal house under with a 12-h light/dark cycle, in polyethylene cages at -22°C and 50% humidity.

A total of 20 rats were euthanized using 100% CO₂. The colons were dissected, emptied of their contents and placed in cold smooth muscle buffer (120 mM NaCl, 4 mM KCl, 2.6 mM KH₂PO₄, 2.0 mM CaCl₂, 0.6 mM MgCl₂, 25 mM HEPES, 14 mM glucose and 2.1% essential amino mixture; pH 7.4). Sections (2-3 cm) of the colon were removed and mounted onto a glass rod. The fat and mesenteric regions were removed, and the longitudinal muscle was separated from the circular layer by radial abrasion with a Kim wipe. The muscle layers were released from the mucosal/submucosal layers using micro dissection and cut into small sections using surgical scissors. Equal amounts (1.5 g/well) were placed in 6-well plates containing MEM with penicillin (200 U/ml), streptomycin (200 µg/ml), gentamycine (100 µg/ml³) and amphotericin B (2.5 µg/ml), and placed in a 37°C incubator.

TNF-α and IL-1β exposure. Longitudinal smooth muscle tissues from rat colons were exposed for 24 h to either of the medium alone (control, n=5) or medium supplemented with 10 ng/ml recombinant human TNF-α (n=3; R&D Systems, Inc.; cat. no. 210-0005) or 10 ng/ml IL-1β (n=3; Sigma-Aldrich; Merck KGaA; cat. no. 1457756001) for 24 h. The roles of Ca²⁺ and PKA were tested by pre-treating smooth muscle tissues with 1 µM BABTA-AM (n=3; R&D Systems, Inc.) or 10 µg/ml IL-1β (n=3; Sigma-Aldrich; Merck KGaA; cat. no. G7611) for 24 h. The concentration of BDNF in the samples was calculated using a standard curve. Data are expressed relative to the total protein concentration and compared with the control, TNF-α and IL-1β treated groups.

Statistical analysis. Data are presented as the mean ± the standard error of the mean. Each experiment used at least three animals and was repeated three times. GraphPad PRISM version 8 (GraphPad Software, Inc.) was used for statistical analysis. ANOVA with a post hoc Tukey's test was used for multiple comparisons. P<0.05 was considered to indicate a statistically significant difference.

Results

Effect of TNF-α and IL-1β on BDNF expression in the longitudinal muscles of the rat colon. The effect of TNF-α and IL-1β on BDNF protein content in smooth muscle tissues was evaluated. Both TNF-α and IL-1β significantly upregulated BDNF protein expression levels compared with the control (control, 111.7±8.11; TNF-α, 228±29.51; IL-1β, 175.8±12.03, P=0.0057; Fig. 1). The effect of TNF-α was greater than that of IL-1β, but was not statistically significant.

Effect of TNF-α and IL-1β on BDNF secretion in the longitudinal smooth muscle of rat colons. To study the effects of TNF-α and IL-1β on the secretion of BDNF, longitudinal smooth muscle tissues were treated with TNF-α and IL-1β for 24 h and the quantity of BDNF release into the media was determined using ELISA. After 24 h of incubation with either of the cytokines, secretion of BDNF was significantly increased compared with the control (control, 36.67±6.888; TNF-α, 75.33±7.42; P=0.0067; IL-1β, 64.25±4.54, P=0.0246; Fig. 2). The increase in BDNF secretion induced by TNF-α was greater than that of IL-1β, but was not statistically significant.

Role of Ca²⁺ and PKA in mediating the effects of IL-1β on BDNF expression in longitudinal muscle tissues. To determine
Figure 1. Expression of BDNF synthesis induced by TNF-α and IL-1β. Incubation of rat colon smooth muscle tissue with 10 ng/ml TNF-α and with 10 ng/ml of IL-1β for 24 h increased expression of BDNF. Data are presented as the mean ± the standard error of the mean. BDNF; brain derived neurotrophic factor; TNF-α, tumor necrosis factor-α; IL-1β, interleukin-1β.

Figure 2. Secretion of BDNF induced by TNF-α and IL-1β. Incubation of rat colon smooth muscle tissues with 10 ng/ml TNF-α or 10 ng/ml of IL-1β for 24 h increased secretion of BDNF. Data are presented as the mean ± the standard error of the mean. BDNF, brain derived neurotrophic factor; TNF-α, tumor necrosis factor-α; IL-1β, interleukin-1β.

Figure 3. Effect of BAPTA-AM and PKA inhibitors on the expression of BDNF induced by 10 ng/ml IL-1β. Incubation of smooth muscle tissues for 24 h with the Ca²⁺ chelating agent BAPTA-AM significantly reduced the increase in BDNF expression levels induced by 10 ng/ml IL-1β. Treatment with PKA decreased BDNF expression levels. Data are presented as the mean ± the standard error of the mean. BDNF, brain derived neurotrophic factor; IL-1β, interleukin-1β; PKA, protein kinase A.

Role of Ca²⁺ and PKA in mediating the effect of TNF-α on BDNF expression in longitudinal muscle tissues. To determine the mechanism of action underlying the IL-1β-mediated increase in BDNF expression, the roles of Ca²⁺ and PKA were both investigated, as both are associated with the responses evoked by IL-1β, and are known activators of BDNF gene transcription (10,11). Incubation of longitudinal muscle tissues with IL-1β for 24 h in the presence of 1 µM BAPTA-AM to chelate Ca²⁺, abrogated the ability of IL-1β to increase BDNF expression (control, 111.7±8.11; IL-1β, 175.8±12.03, P=0.0052 vs. control; IL-1β-BAPTA-AM, 118.0±4.041, P=0.913 vs. control; IL-1β vs. IL-1β-BAPTA-AM; Fig. 3). However, the effect of 1 µM of PKA inhibitor 6-22 Amide did not significantly alter the effect of IL-1β on BDNF expression (control, 111.7±8.11; IL-1β, 175.8±12.03; IL-1β-PKA inhibitor, 152.3±10.48; P=0.3720, IL-1β vs. IL-1β-PKA).

Role of Ca²⁺ and PKA in mediating the effect of TNF-α on BDNF expression in longitudinal muscle tissues. To determine the mechanism of action underlying TNF-α on BDNF expression, the role of Ca²⁺ and PKA was investigated, as both are associated with TNF-α-mediated effects. Incubation of longitudinal muscle tissues with 10 ng/ml TNF-α for 24 h in the presence of 1 µM BAPTA-AM to chelate Ca²⁺ abrogated the ability of TNF-α to increase BDNF expression (control, 111.7±8.11; TNF-α, 228±29.51, P=0.0096 vs. control; TNF-α-BAPTA-AM, 115.7±8.686, P=0.6934 vs. control; P=0.0316, TNF-α vs. TNF-α-BAPTA-AM; Fig. 4). Furthermore, PKA inhibition with 1 µM of 6-22 Amide abolished the effects of TNF-α on BDNF expression (control, 111.7±8.11; TNF-α, 23±29.51, P=0.0096 vs. control; TNF-α-PKA inhibitor, 129±6.35, P=0.9834 vs. control; P=0.0110, TNF-α vs. TNF-α-PKA).

Role of Ca²⁺ and PKA in mediating the effect of IL-1β on BDNF secretion from longitudinal muscle tissues. As BDNF is secreted in an activity dependent manner in response to elevated intracellular Ca²⁺, the role of general Ca²⁺ on BDNF secretion in response to IL-1β was assessed. Incubation of rat smooth muscle tissue for 24 h with IL-1β in the presence of 1 µM of BAPTA-AM resulted in complete inhibition of IL-1β on BDNF secretion (control, 36.67±6.89; IL-1β, 64.25±4.54, P=0.0327 vs. control; IL-1β-BAPTA-AM, 32.67±8.57, P=0.9656 vs. control; P=0.0157, IL-1β vs. IL-1β-BAPTA-AM; Fig. 5). Treatment with PKA did not significantly decrease BDNF secretion (control, 36.67±6.888; IL-1β, 64.25±4.54; IL-1β-PKA inhibitor, 50.67±2.60; P=0.3882, IL-1β vs. IL-1β-PKA).

Role of Ca²⁺ and PKA in mediating the effect of TNF-α on BDNF secretion from longitudinal muscle tissues. Incubation of rat smooth muscle tissues for 24 h with TNF-α in the presence of 1 µM of BAPTA-AM abolished the ability of TNF-α to increase BDNF secretion (control, 36.67±6.89; TNF-α, 75.33±7.42, P=0.0188 vs. control; TNF-α-BAPTA-AM, 41±7.55, P=0.6934 vs. control; P=0.0303, TNF-α vs. TNF-α-BAPTA-AM; Fig. 6). However, 1 µM of 6-22 Amide did not significantly inhibit BDNF secretion induced by
Discussion

In the present study, it was demonstrated that the exogenous proinflammatory cytokines, TNF-α and IL-1β, upregulated BDNF protein expression and secretion in rat colon smooth muscle tissues. Furthermore, the expression and secretion of BDNF by TNF-α and IL-1β were likely Ca²⁺-dependent. Finally the effect of TNF-α on the expression and secretion of BDNF was regulated by the cAMP/PKA pathway as well.

Previously, it has been shown that BDNF and its receptors are present in adult rat colon smooth muscle, and its expression is increased in inflammatory diseases such as UC (8,12). Furthermore, exogenous BDNF enhances cholinergic contraction of the smooth muscle cells associated with IBD (9). In the present study, it was demonstrated that TNF-α and IL-1β significantly upregulated BDNF levels in rat colon smooth muscle tissues. In agreement with the results of the present study, inflammatory cytokines enhanced BDNF expression and secretion in airway smooth muscle cells (13). The effect of these cytokines may underlie functional and structural changes which take place during bowel inflammation. For example, the reported changes in gut motility during colitis and in response to inflammatory cytokines (14) may be due to the increase in expression/secretion of BDNF which was induced by TNF-α and IL-1β, as demonstrated in the present study. The effect of BDNF on gut motility is well established. BDNF enhances stool frequency in patients treated with a higher dose of BDNF, enhances gastrointestinal and colonic transit in human subjects, accelerates myoelectric activity in the gastrointestinal tract and enhances peristalsis in the rat colon (15-18). Furthermore, BDNF may account for the abdominal pain and visceral hypersensitivity experienced by patients with gut inflammation (19). Intraperitoneal BDNF injections results in increased pain sensation in response to colon distension in healthy rats, and administration of BDNF antibodies inhibited visceral hypersensitivity in experimental colitis (19), and BDNF heterogeneous knockout animals experienced notably less pain compared with wild type mice in a model of colitis (20). Furthermore, BDNF increases the expression of calcitonin gene-related peptide during colitis, which is considered a pain mediator (21). The results of the present study suggest that TNF-α and IL-1β may underlie the increase in BDNF expression.

An additional aim of the present study was to delineate the mechanisms underlying the increase in BDNF expression and secretion mediated by proinflammatory cytokines.

Figure 4. Effect of BAPTA-AM and PKA inhibitors on the expression of BDNF induced by 10 ng/ml TNF-α. Incubation of smooth muscle tissues for 24 h with the Ca²⁺ chelating agent BAPTA-AM or a PKA inhibitor both abolished the increase in BDNF expression induced by 10 ng/ml TNF-α. Data are presented as the mean ± the standard error of the mean. BDNF, brain derived neurotrophic factor; TNF-α, tumor necrosis factor-α; PKA, protein kinase A.

Figure 5. Effect of BAPTA-AM and PKA inhibitors on the secretion of BDNF induced by 10 ng/ml IL-1β. Incubation of smooth muscle tissues for 24 h with the Ca²⁺ chelating agent BAPTA-AM abolished the increase in BDNF secretion induced by 10 ng/ml IL-1β. PKA inhibitor did not significantly affect secretion induced by IL-1β. Data are presented as the mean ± the standard error of the mean. BDNF, brain derived neurotrophic factor; IL-1β, interleukin-1β; PKA, protein kinase A.

Figure 6. Effect of BAPTA-AM and PKA inhibitors on the secretion of BDNF induced by 10 ng/ml TNF-α. Incubation of smooth muscle tissues for 24 h with the Ca²⁺ chelating agent BAPTA-AM abolished the increase in BDNF secretion induced by 10 ng/ml TNF-α. BDNF secretion was not significantly affected by PKA inhibitor treatment. Data are presented as the mean ± the standard error of the mean. BDNF, brain derived neurotrophic factor; TNF-α, Tumor Necrosis Factor-α; PKA, protein kinase A.
BDNF expression by both TNF-α and IL-1β was Ca²⁺ and PKA dependent. BDNF gene expression is under the control of intracellular Ca²⁺ and PKA levels (22). Stimuli that result in an increase in the intracellular Ca²⁺ levels activate BDNF transcription and synthesis by activating Ca²⁺/calmodulin, which phosphorylates calmodulin-dependent protein kinase I (CaMKII). CaMKII, in turn, phosphorylates cAMP response element-binding protein (CREB) which results in BDNF transcription and translation (23). Although in the present study, Ca²⁺ levels were not measured in response to TNF-α and IL-1β, it has previously been shown that these cytokines may increase intracellular Ca²⁺ levels in various types of cells, including smooth muscle cells (24). In agreement with the results of the present study, TNF-α upregulates BDNF protein in primary astrocytes (25), monocytes (26), neurons (27) and smooth muscle cells (13). In airway smooth muscle cells, elevation of intracellular Ca²⁺ and PKA are essential for TNF-α induced BDNF synthesis (13).

BDNF is secreted in an activity dependent manner that is regulated by intracellular Ca²⁺ levels (28). In the present study, it was shown that the TNF-α and IL-1β induced BDNF release was inhibited by the chelation of intracellular and extracellular Ca²⁺ using BAPTA-AM. As the source of Ca²⁺ was not investigated, future studies should use different pharmacological inhibitors of intracellular and extracellular Ca²⁺ routes, to elucidate the pathways involved in cytokine induced BDNF release.

BDNF may act in a positive feedback loop to induce its synthesis and release (28). BDNF activates three primary signaling pathways; ERK, PI3K and phospholipase C, resulting in increases in intracellular Ca²⁺ levels (29). Thus in future studies the effects of these cytokines in the presence and absence of tropomyosin-related kinase B should be investigated to assess this possibility. In airway smooth muscle cells, cytokine-mediated BDNF release was Ca²⁺ dependent and involved a positive feedback mechanism mediated by BDNF, acting in an autocrine and paracrine manner (13), which may also apply to colon smooth muscle cells.

The reported role of cAMP/PKA in cytokine-induced BDNF synthesis and release is supported by several previous studies. It was previously shown that substance P (SP) and pituitary adenylate cyclase activating peptide (PACAP) induced BDNF synthesis in intestinal smooth muscle cells in a cAMP/PKA dependent manner (30). PKA inhibition resulted in reduced BDNF synthesis in response to SP or PACAP treatment (30). In neurons from rat hippocampi, BDNF expression was under the control of PKA activation and the subsequent phosphorylation of CREB (31-33) these data demonstrate that cytokines stimulation of BDNF synthesis in colon smooth muscle cells is PKA dependent as well.

In conclusion, TNF-α and IL-1β upregulated BDNF synthesis and release in rat colon smooth muscle cells. Both cytokines depend on Ca²⁺ for their action on BDNF synthesis and release; however, PKA may have been more involved in BDNF synthesis rather than release. These data may highlight novel potential avenues for treatment of IBD, by targeting BDNF.
