A \textit{k-linear} triangulated category without a model

ALICE RIZZARDO AND MICHEL VAN DEN BERGH

ABSTRACT. In this paper we give an example of a triangulated category, linear over a field of characteristic zero, which does not carry a DG-enhancement. The only previous examples of triangulated categories without a model have been constructed by Muro, Schwede and Strickland. These examples are however not linear over a field.

1. INTRODUCTION

1.1. Main result. The only known examples of triangulated categories without model (not even topological) are given in [9]. The examples in loc. cit. are not linear over a field and furthermore they depend on some special properties of the number 2. In particular they satisfy $2 \neq 0$ but $4 = 0$.

In this paper we discuss triangulated categories over a field $k$ of characteristic zero. In this case the appropriate notion of a model is a DG-enhancement [3, 4, 8], or what amounts to the same thing: an $A_\infty$-enhancement (see §1). Our main result is an example of a \textit{k-linear} triangulated category which does not carry an $A_\infty$-enhancement. This in particular answers positively what is described as a challenging question in the survey [4] by Canonaco and Stellari, namely Question 3.8. Our example also provides a negative answer to Question 3.3 of their survey.

To describe the example we have to introduce some notation. Fix a natural number $n \geq 3$ and let $k$ be either a field of characteristic zero or an infinite field of characteristic > $n$. Let $R = k[x_1, \ldots, x_n]$ and let $K$ be the quotient field of $R$. Furthermore let $R[\epsilon]$ be the $R$-linear DG-algebra with $|\epsilon| = -n + 2$, $\epsilon^2 = 0$, $d\epsilon = 0$. Let $C(R, R)$ be the Hochschild complex of $R$ and let $HH^n(R, R) = H^n(C(R, R))$. Let $T^n_{R/k} = \Lambda^n_R \text{Der}_R(R, R)$. The HKR theorem furnishes an inclusion $T^n_{R/k} \subset Z^n C(R, R)$ which induces an isomorphism $\cong \text{HH}^n(R, R)$. For $\eta \in T^n_{R/k}$ we let $R[\eta]$ be the $k[\epsilon]$-linear $A_\infty$-deformation of $R[\epsilon]$ whose only non-trivial higher multiplication is given by $\epsilon \eta$.

Theorem 1.1 (see §11.3). Assume $n \geq 14$ and $\eta \neq 0$. Then there exists a triangulated category without $A_\infty$-enhancement with semi-orthogonal decomposition $\langle D(K), D(R[\eta]) \rangle$.

In the next few sections we discuss in more detail the ingredients that go into the construction of this example.

1Notwithstanding what we say here, almost everything we do is valid in arbitrary characteristic. However in finite characteristic we would also have to consider topological enhancements and we do not discuss these in the current paper.

2We can always transform an $A_\infty$-enhancement into a DG-enhancement by taking its DG-hull. See [7, p127] or [12, Appendix C].
1.2. Pre-triangulated $A_n$-categories. An $A_\infty$-category [7] is a DG-graph equipped with higher compositions $(m_i)$, which satisfy certain natural quadratic relations. If only $m_i$ with $i \leq n$ are defined then we obtain the corresponding notion of an $A_n$-category. As a general principle, for any $A_\infty$-notion there is a corresponding $A_n$-notion in which we consider only operations with $\leq n$ arguments and we require the axioms to only hold for expressions with $\leq n$ arguments. Facts about $A_\infty$-categories remain valid for $A_n$-categories as long as they only involve such expressions. It is useful to note that if $a$ is an $A_n$-category for $n \geq 3$ then its “homotopy category” $H^0(a)$ is an honest category.

A DG-category is an $A_\infty$-category with $m_i = 0$ for $i > 2$. In their seminal paper [3] Bondal and Kapranov introduced pre-triangulated DG-categories which, in particular, have the property that their homotopy category is canonically triangulated. Their most striking insight is that, whereas a triangulated category is an additive category with extra structure, a pre-triangulated DG-category is a DG-category with extra properties.

It is well understood how to define the analogous notion of a pre-triangulated $A_\infty$-category (see [2]). An $A_\infty$-category is pre-triangulated if the natural functor $a \to \text{Tw } a$ is a quasi-equivalence, where $\text{Tw } a$ is the category of twisted complexes over $a$. It is easy to see that this is equivalent to $a$ being closed under suspensions, desuspensions and cones of closed maps, up to isomorphism in $H^0(\text{Tw } a)$. Stating these properties explicitly requires only a finite number of higher operations on $a$ and so they make sense for $A_n$-categories for $n \gg 0$.

For any $A_\infty$-category $a$, $H^0(\text{Tw } a)$ is canonically triangulated and hence if $a$ is pre-triangulated then $H^0(a)$ is also canonically triangulated. Now it is intuitively clear that it should be possible to prove this using only a finite number of the higher operations on $a$. It then follows that it must be possible to define for $n \gg 0$ a notion of a pre-triangulated $A_n$-category which induces a canonical triangulation on its homotopy category.

Unfortunately, carrying out this program naïvely using explicit equations seems to be a nightmare. Therefore we are forced carry over some more advanced technology from the $A_\infty$-context. This is done in §§5, §6. The main difficulty we face is that the definition of $\text{Tw } a$ depends on higher compositions in $a$ of unbounded arity and therefore does not generalize to $A_n$-categories. Luckily this issue can be solved by considering twisted complexes of uniformly bounded length. In fact we only need $\text{Tw } \leq 1 a$, which consists of twisted complexes of length two. This leads to our first main result.

**Theorem 1.2** (Lemma 6.6, Definition 6.10, Theorem 8.3). If $a$ is an $A_n$-category then $\text{Tw } \leq 1 a$ is an $A_{[(n-1)/2]}$-category. If $n \geq 7$ then we say that $a$ is pre-triangulated if $H^*(a) \to H^*(\text{Tw } \leq 1 a)$ is a graded equivalence. If $a$ is pre-triangulated and $n \geq 13$ then $H^0(a)$ is canonically triangulated.

The number 13 seems quite high and we are rather curious if it can be reduced.

1.3. Gluing. We have already pointed out that if $a$ is an $A_n$-category then its “pre-triangulated hull” $\text{Tw } a$ is not well-defined. So while we have a satisfactory theory of pre-triangulated $A_n$-categories, it is unclear how to actually construct non-trivial examples of them. Luckily there is one approach which works very well. It turns out that pre-triangulated $A_n$-categories admit a “gluing” procedure and starting from pre-triangulated $A_\infty$-categories we can in this way produce pre-triangulated $A_n$-categories which are not themselves $A_\infty$-categories.

---

3In this introduction we will follow tradition by viewing a triangulated category as an additive category. However in the main body of the paper we will equip a triangulated category with its canonical graded enrichment. This means in particular that we use $H^*(a)$ rather than $H^0(a)$. See §3 for the rationale for this choice.
Let us first review gluing in the context of triangulated categories. If \( A, B \) are triangulated categories and \( \mathcal{M} \) is a \( B - A \)-bimodule (an additive bifunctor \( A^\circ \times B \rightarrow Ab \)) then a gluing of \( A, B \) across \( \mathcal{M} \) is a triangulated category \( C \) together with a semi-orthogonal decomposition \( C = \langle A, B \rangle \) such that \( C(A, B) = \mathcal{M}(A, B) \) for \( A \in \text{Ob}(A), B \in \text{Ob}(B) \). The data \( (A, B, \mathcal{M}) \) determines the objects of \( C \) up to isomorphism and there is a long exact sequence relating the Hom-spaces in \( C \) to those in \( A, B \) and the elements of \( \mathcal{M} \). However this is as far as it goes. Triangulated categories are too flabby to allow one to fully construct \( C \) from the triple \( (A, B, \mathcal{M}) \).

On the other hand if \( a, b \) are \( \mathbb{A}_\infty \)-categories and \( M \) is an \( \mathbb{A}_\infty \)-\( b \)-\( a \)-module then it is a routine matter to define an \( \mathbb{A}_\infty \)-gluing category \( c = a \coprod_M b \) such that if \( a, b \) are pre-triangulated then so is \( c \) and there is a semi-orthogonal decomposition \( H^0(c) = \langle H^0(a), H^0(b) \rangle \) with associated bimodule \( H^0(M) \).

To prove that \( c \) is pre-triangulated we have to prove it is closed under cones of closed maps and again it is clear that this will only involve a finite number of higher operations. Hence the theory can be developed for \( \mathbb{A}_\infty \)-categories. This leads to our next main result.

**Theorem 1.3** (Theorem 9.5). Assume that \( n \geq 13 \) and that \( a, b \) are pre-triangulated \( \mathbb{A}_n \)-categories and that \( M \) is an \( \mathbb{A}_n \)-\( b \)-\( a \)-bimodule. Then \( a \coprod_M b \) is a pre-triangulated \( \mathbb{A}_{n-1} \)-category. If \( n \geq 14 \), so that \( H^0(a \coprod_M b) \) is triangulated by Theorem 1.2, then we have a semi-orthogonal decomposition \( H^0(a \coprod_M b) = \langle H^0(a), H^0(b) \rangle \) whose associated bimodule is \( H^0(M) \).

1.4. **The counterexample.** The counterexample we describe in Theorem 1.1 will be more specifically of the form \( D = H^0(a \coprod_M b) \) where \( a, b \) are pre-triangulated \( \mathbb{A}_\infty \)-categories and \( M \) is an \( \mathbb{A}_\infty \)-\( b \)-\( a \)-bimodule. We will in fact assume that \( M \) is obtained from an \( \mathbb{A}_{n-1} \)-functor \( F : a \rightarrow b \) via \( M(A, B) = b(F(A, B)) \). By Theorems 1.2 and 1.3, \( D \) is canonically triangulated for \( n \gg 0 \). Moreover any \( \mathbb{A}_\infty \)-enhancement on \( D \) induces \( \mathbb{A}_\infty \)-enhancements \( a', b' \) on \( H^0(a), H^0(b) \) as well as an \( \mathbb{A}_\infty \)-functor \( F' : a' \rightarrow b' \) such that \( H^0(F') = H^0(F) \). One may hope to be able to prove that such \( F' \) does not exist. This then implies that an \( \mathbb{A}_\infty \)-enhancement on \( D \) does not exist.

We carry out this program with \( a, b \) being the standard \( \mathbb{A}_\infty \)-enhancements of \( D(K), D(R_\eta) \) for \( \eta \neq 0 \) (see §11). The exact functor
\[
f : D(K) \rightarrow D(R_\eta) : K \rightarrow K_\eta
\]
(defined using the fact that \( D(K) \) is the category of graded \( K \)-vector spaces, equipped with its unique triangulation) lifts to an \( \mathbb{A}_{n-1} \)-functor \( F \); by [12, Lemma 7.2.1] this follows from the fact that \( H^i(K_\eta) = 0 \) for \( i = 0, \ldots, -n + 3 \). However, using the fact that \( \eta \neq 0 \) one deduces that \( f \) does not lift to an \( \mathbb{A}_\infty \)-functor, even if we are allowed to change enhancements. This follows from the fact that the enhancement on \( D(R_\eta) \) is actually unique in a weak, but sufficient, sense. This is proved using higher Toda brackets (see Proposition 11.8). This finishes the proof that an \( \mathbb{A}_\infty \)-enhancement on \( D \) does not exist.

2. **Acknowledgement**

The authors thank Alexey Bondal and Dmitri Orlov for several interesting discussions around the possibility of gluing a non-enhanceable functor to obtain a triangulated category without a model.

3. **Notation and Conventions**

Below \( k \) is an arbitrary field, except in §11.3 where it will be subject to some restrictions. Unless otherwise specified, categories are pre-additive (enriched in abelian groups), except when we are in an \( \mathbb{A}_n \)-context. In that case we assume all objects and constructions are \( k \)-linear.

Triangulated categories will be equipped with their canonical graded enhancement (see §4.4). The motivation for this is that the principal “homotopy invariant” associated to an \( \mathbb{A}_n \)-category \( a \) is \( H^*(a) \) as
$H^0(\alpha)$ loses too much information in general. If $\alpha$ is pre-triangulated then $H^*(\alpha)$ can be recovered from $H^0(\alpha)$ together with a “shift functor” but, since the shift functor is not canonical (despite being unique up to unique isomorphism), this extra step creates some complications, notably with signs, which are often unnecessary. In any case, not all $A_\infty$-categories we will encounter will be pre-triangulated.

In situations where the shift functor is canonical we will use it. The most obvious case is graded objects over an abelian category $\mathcal{A}$. If $A^* = (A_i)_{i \in \mathbb{Z}}$ is such an object then we put $\Sigma^0(A_i) = A_{i+n}$. If $f : A^* \to B^*$ has degree $i$ then we put $\Sigma^0 f = (-1)^m f$. If $A^*$ is a graded object over $\mathbb{A}b$ and $x \in A_j$ then we write $sx$ for $x$ considered as an element of $(\Sigma A^*)_j$. The “degree change operator” $s$ makes it easy to find the correct sign in formulas using the Koszul convention.

4. Preliminaries on Triangulated Categories

4.1. Graded categories. For us a graded category is a category enriched in $\mathbb{Z}$-graded abelian groups.

Assume that $\mathcal{A}$ is a graded category and let $X \in \text{Ob}(\mathcal{A})$. A suspension of $X$ is a pair $(Y, \eta)$ where $Y \in \text{Ob}(\mathcal{A})$ and $\eta \in \mathcal{A}(X, Y)_{-1}$ is invertible. Conversely we call $(X, \eta)$ a desuspension of $Y$. (De)suspensions are clearly functorial if they exist. So if every object $X$ has a suspension $(Y, \eta)$ we may define a functor $\Sigma : \mathcal{A} \to \mathcal{A}$ by putting $\Sigma X = Y$ and requiring for maps $f \in \mathcal{A}(X, Y')$ that the following diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\eta} & \Sigma X \\
\downarrow f & & \downarrow \Sigma f \\
X' & \xrightarrow{\eta} & \Sigma X'
\end{array}
\]

commutes up to a sign $(-1)^{|f|}$. It is clear that $\Sigma$ is unique up to unique equivalence. We say that $\mathcal{A}$ has a shift functor $\Sigma$ if every object has a suspension and a desuspension and $\Sigma$ is as above. In this case $\Sigma$ is an auto-equivalence.

4.2. Graded categories from pre-additive categories with shift functor. Now assume that $\mathcal{A}$ is a pre-additive category (i.e. a category enriched in abelian groups) equipped with an auto-equivalence $\Sigma$. Then we can make $\mathcal{A}$ into a graded category $\tilde{\mathcal{A}}$ with the same objects by putting for $n \in \mathbb{Z}$

\[
\tilde{\mathcal{A}}(A, B)_n := \mathcal{A}(A, \Sigma^n B)
\]

and with compositions

\[
\tilde{\mathcal{A}}(B, C)_m \times \tilde{\mathcal{A}}(A, B)_n \to \tilde{\mathcal{A}}(A, C)_{m+n} : (g, f) \mapsto (-1)^{nm} \Sigma^n g \circ f
\]

We obtain that $\Sigma$ is a shift functor on $\tilde{\mathcal{A}}$ in the sense of §4.1.

4.3. Triangles. A triangle in a graded category $\mathcal{A}$ is a diagram

\[
\begin{array}{ccc}
& & C \\
& h \swarrow & \\
A & \xrightarrow{f} & B
\end{array}
\]

with $A, B, C \in \text{Ob}(\mathcal{A})$ and $|f| = |g| = 0, |h| = 1$. To save space a triangle will usually be written in linear form

\[
A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} A.
\]
If \( a \) is equipped with a shift functor then a triangle can also be written in “traditional” form

\[
A \xrightarrow{f} B \xrightarrow{g} C \rightarrow \Sigma A.
\]

A morphism of triangles is given by three degree zero morphisms fitting into the obvious commutative diagram.

4.4. **Triangulated categories as graded categories.** We will assume that the reader is familiar with the standard axioms for triangulated categories [14]. If \((\mathcal{T}, \Sigma)\) is triangulated category in the traditional sense then it can be made into a graded category as in §4.2. In this section we will reformulate the usual axioms of triangulated categories in such a way that they do not explicitly refer to a shift functor.

**Definition 4.1.** A **triangulated** category \( \mathcal{T} \) is a graded category equipped with a collection of “distinguished” triangles such that

**TR0** \( \mathcal{T} \) admits (possibly empty) finite direct sums and every object has a suspension and a desuspension.

**TR1** • For any object \( X \in \text{Ob}(\mathcal{T}) \) the following triangle is distinguished:

\[
X \xrightarrow{id_X} X \xrightarrow{0_0} 0 \xrightarrow{0_1} X
\]

where 0 is a zero object (which exists by TR0) and where \( 0_i \) is the zero morphism in \( \mathcal{T}(U, V)_i \).
• For any morphism \( u : X \rightarrow Y \) in \( \mathcal{T} \) of degree zero, there is an object \( Z \) (called a mapping cone of the morphism \( u \)) fitting into a distinguished triangle

\[
X \xrightarrow{u} Y \xrightarrow{v} Z \xrightarrow{(1)} X
\]

Any triangle isomorphic to a distinguished triangle is distinguished.

**TR2** If

\[
\begin{array}{c}
Z \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
X \\
\downarrow u \\
Y
\end{array}
\]

is a distinguished triangle then so are the two “rotated triangles”

\[
\begin{array}{c}
X' \\
\downarrow \eta u \\
X \\
\downarrow \eta^{-1} u \\
Y
\end{array}
\]

\[
\begin{array}{c}
Z' \\
\downarrow -u \eta \\
Z \\
\downarrow y^{-1} v \\
Y
\end{array}
\]

where \( X \xrightarrow{u} X' \) is a suspension of \( X \) and \( Z' \xrightarrow{v} Z \) is a desuspension of \( Z \).

\(^4\)Morphisms in a graded category whose degree is not specified are assumed to have degree zero. This convention is maintained throughout this document.
TR3 A commutative diagram of solid arrows

\[
\begin{array}{c}
X \rightarrow Y \rightarrow Z \rightarrow X \\
\downarrow \downarrow \downarrow \\
X' \rightarrow Y' \rightarrow Z' \rightarrow X'
\end{array}
\]

in which the rows are distinguished can be completed with the dotted arrow.

TR4 For every upper cap of an octahedron (drawn on the left) there is a corresponding lower cap (drawn on the right).

\[
(4.1)
\]

such that in addition the compositions \(Y \rightarrow Z \rightarrow Y'\) and \(Y \rightarrow Z' \rightarrow Y'\) are the same and similarly the compositions \(Y' \rightarrow X \rightarrow Y\) and \(Y' \rightarrow X' \rightarrow Y\) are the same. In the diagram the triangles marked \(d\) are distinguished and those marked with \(\bigcirc\) are commutative,

5. Preliminaries about \(A_n\)-categories

Let \(n \geq 0\). As a general principle, for any \(A_\infty\)-notion there is a corresponding \(A_n\)-notion in which we consider only operations with \(\leq n\) arguments and we require the axioms to only hold for expressions with \(\leq n\) arguments. Facts about \(A_\infty\)-categories remain valid for \(A_n\)-categories as long as they only involve such expressions. We discuss this below. Throughout we place ourselves in the strictly unital context.

5.1. \(A_n\)-categories and functors.

**Definition 5.1 ([7]).** An \(A_n\)-category \(a\) is the data of:

- A set of objects \(\text{Ob}(a)\).
- For each couple \((A, A')\) of objects of \(a\), a graded vector space of morphisms \(\text{a}(A, A')\). We call \(\text{a}(A, A')\) the Hom-space between \(A\) and \(A'\). A (homogeneous) element of \(\text{a}(A, A')\) is called a morphism (or sometimes an arrow).
- For each sequence \((A_0, \ldots, A_i)\) of objects of \(a\) with \(1 \leq i \leq n\), “higher” compositions

\[
b_i : \Sigma \text{a}(A_{i-1}, A_i) \otimes \cdots \otimes \Sigma \text{a}(A_0, A_1) \rightarrow \Sigma \text{a}(A_0, A_i)
\]

of degree 1 verifying (\(\ast\)) of [7, definition 1.2.1.1].
• For each object $A$ an identity (or unit) element $\text{id}_A \in a(A, A)_0$ satisfying
  
  
  \begin{align*}
  b_i(\ldots, s \text{id}_A, \ldots) &= 0 & \text{(for } i = 1 \text{ and } 3 \leq i \leq n) \\
  b_2(sf, s \text{id}_A) &= (-1)^{|f|} sf & \text{if } n \geq 2 \\
  b_2(s \text{id}_A, sg) &= sg & \text{if } n \geq 2
  \end{align*}

  If the identities hold for every $i$ then we get the notion of an $A_\infty$-category. Below an $A_n$-category will be silently considered as an $A_m$-category for all $m \leq n$.

  As for $A_\infty$-categories is it sometimes more convenient to express the higher compositions as operations

  \begin{align*}
  m_1 : a(A_{-1}, A_0) \otimes \ldots \otimes a(A_0, A_1) \to a(A_0, A_i)
  \end{align*}

  of degree $2 - n$ where $(m_n)_n$ and $(b_n)_n$ are related by $b_n = s^{-n+1}m_n$ so that in particular using the Koszul convention we obtain

  \begin{align*}
  b_1(sf) &= -sm_1(f) \\
  b_2(g, sf) &= (-1)^{|g|} sm_2(g, f) \\
  b_3(h, g, sf) &= (-1)^{|g|+1} sm_3(h, g, f)
  \end{align*}

  Sometimes we write $df = m_1(f)$ and $gf = m_2(g, f)$. It is useful to consider the case of low $n$.

  (1) An $A_0$-category is simply a directed graph (with distinguished “identity arrows”) whose Hom-spaces are graded vector spaces. We call this a graded graph.

  (2) An $A_1$-category is a graded graph whose arrows form complexes of vector spaces (the differential is given by $m_1$ and it annihilates identity arrows). We call this a DG-graph. A DG-graph $a$ has an associated graded graph $H^*(a)$ obtained by replacing the Hom-spaces in $a$ by their cohomology. A morphism $f$ in $a$ is called closed if $m_1(f) = 0$. We denote by $Z^0a$ the $k$-linear graph which has the same objects as $a$ and whose morphisms are the closed morphisms of degree zero.

  (3) An $A_2$ category is a DG-graph equipped with a bilinear composition of arrows given by $m_2$ (for which the identity arrows behave as unit elements) which is compatible with $m_1$. In particular $m_2$ descends to well-defined operations on $H^*(a)$ and $Z^0a$.

  (4) For $n \geq 3$ the composition on $H^*(a)$ induced by $m_2$ is associative and hence in particular $H^*(a)$ is a graded category.

**Definition 5.2.** An $A_n$-functor $f : a \to b$ between two $A_n$-categories $a$ and $b$ is the data of

• A map on objects $f : \text{Ob}(a) \to \text{Ob}(b)$.

• For each sequence $(A_0, \ldots, A_i)$ of objects of $a$ with $i \leq n$, compositions

  \begin{align*}
  f_i : \Sigma a(A_{-1}, A_i) \otimes \ldots \otimes \Sigma a(A_0, A_1) \to \Sigma b(f(A_0), f(A_i))
  \end{align*}

  of degree zero verifying (**) of [7, definition 1.2.1.2] for $i = 1, \ldots, n$.

  • If $n \geq 1$ then for each $A \in \text{Ob}(a)$ we have $f_i(s \text{id}_A) = s \text{id}_{f(A)}$ and $f_n(\ldots, s \text{id}_A, \ldots) = 0$ for $n \geq 2$.

Again it is instructive to unravel this definition for small values of $n$.

(1) An $A_0$-functor is just a map between sets of objects (there is no compatibility with morphisms).

(2) An $A_1$-functor $f : a \to b$ is a morphism of DG-graphs. In particular we have an induced morphism of graded graphs $H^*(f) := H^*(f_1)$.

(3) If $f$ is an $A_2$-functor for $n \geq 2$ then $H^*(f)$ is compatible with compositions. In particular, if $f$ is an $A_3$-functor between $A_3$-categories then $H^*(f)$ is a graded functor.
Like $A_m$-notions one may also approach $A_n$-notions via cocategories. Let $a$ be a graded graph. Then $(Ba)_{≤ n}$ is the graded cocategory with Hom-spaces

$$(Ba)_{≤ n}(A, B) = \bigoplus_{i=1}^n (\Sigma a)^{θ_i}(A, B)$$

(5.2)

$$(\Sigma a)^{θ_i}(A, B) = \bigoplus_{A=A_0\ldots A_i=B} Σ a(A_{i-1}, A_i) \otimes \ldots \otimes Σ a(A_0, A_1)$$

equipped with the usual bar coproduct. I.e. if $(sf_{i-1} \ldots |sf_0) := sf_{i-1} \otimes \ldots \otimes sf_0 \in (Σ a)^{θ_i}$ then

$$Δ(sf_{i-1} \ldots |sf_0) = \sum_{j=1}^{i-1} (sf_{j-1} \ldots |sf_j) \otimes (sf_{j-1} \ldots |sf_0)$$

If we ignore the compatibility with units then an $A_n$-structure on $a$ is the same as a codifferential on $(Ba)_{≤ n}$, i.e. a coderivation $b$ of degree one satisfying $bob = 0$. Similarly, ignoring units, an $A_n$-functor $f : a → b$ is the same as a cofunctor $(Ba)_{≤ n} → (Bb)_{≤ n}$ commuting with the codifferentials on $(Ba)_{≤ n}$ and $(Bb)_{≤ n}$. With this observation one may define the composition of $A_n$-functors simply as the composition of the corresponding cofunctors.

5.2. Some auxiliary definitions.

Definition 5.3. Let $f : a → b$ be an $A_m$-functor between $A_n$-categories, for $m ≤ n$. Then

1. $f$ is strict provided $m ≥ 1$ and $f_i = 0$ for $i ≥ 2$. Equivalently $f_1$ commutes with higher compositions with arity at most $m$.
2. $f$ is fully faithful if it is strict and for all $A, A' \in \text{Ob}(a)$ we have that $a(A, A') → b(f A, f A')$ is an isomorphism of graded vector spaces.
3. $f$ is a quasi-fully faithful if $m ≥ 2, n ≥ 3$ and $H^*(f) : H^*(a) → H^*(b)$ is fully faithful.
4. $f$ is a quasi-isomorphism if $m ≥ 2, n ≥ 3$ and $H^*(f) : H^*(a) → H^*(b)$ is an isomorphism.
5. $f$ is a quasi-equivalence if $m ≥ 2, n ≥ 3$ and $H^*(f) : H^*(a) → H^*(b)$ is an equivalence.

5.3. The category of functors between $A_n$-categories. Here we discuss some concepts from [7, Chapter 8]. As indicated above, the (decomposable) arrows of $(Ba)_{≤ n}$ are usually written as $(sf_{i-1} \ldots |sf_0)$ for a path of $1 ≤ i ≤ n$ composable arrows $f_0, \ldots, f_{i-1}$ in $a$. We let $(B^+a)_{≤ n}$ be the coaugmented cocategory obtained by also admitting empty paths $()]A$ starting and ending in $A ∈ \text{Ob}(a)$ (see §2.1.2 in loc. cit.). More precisely we have

$$(B^+a)_{≤ n}(A, B) = \begin{cases} (Ba)_{≤ n}(A, B) & \text{if } A ≠ B \\ k(A) \oplus (Ba)_{≤ n}(A, A) & \text{if } A = B. \end{cases}$$

with $[]A = 0$. The coproduct $Δ^+(t)$ for $t ∈ (Ba)_{≤ n}(A, B)$ is defined as

$$Δ^+(t) = (]A) \otimes t + t \otimes (]A) + Δ(t),$$

where $Δ$ is the coproduct on $(Ba)_{≤ n}$ and furthermore $Δ^+([]A) = (]A) ⊗ (]A)$. If $(Ba)_{≤ n}$ is equipped with a codifferential $b$ then we extend it to $(B^+a)_{≤ n}$ by putting $b([]A) = 0 ∈ a(A, A)$.

Given two $A_n$-categories $c$ and $b$, denote by $A_n(c, b)$ the set of $A_n$-functors $c → b$. Now assume that $a, b$ are respectively $A_m, A_n$-categories for $m ≤ n − 1$. We will equip $A_m(a, b)$ with the structure of an $A_{n-m}$-category as follows:
**Definition 5.4** (Morphisms in $A_m(a, b)$). Assume $m \leq n - 1$. Let $f_1, f_2 : a \to b$ be $A_m$-functors. We view these as cofunctors $(B^+a)_{\leq m} \to Bb_{\leq n}$ by putting $f_{i,0}(\cdot)_A := f_{i,0}(\cdot)_A = 0$. Then

$$\Sigma \text{Hom}(f_1, f_2) = \{ h \in \text{coDer}_{f_1, f_2}(B^+a_{\leq m}, Bb_{\leq n}) \mid \forall A \in \text{Ob}(a) : h(\cdots \otimes s_{id_A} \otimes \cdots) = 0 \}$$

Here coDer$_{f_1, f_2}((B^+a)_{\leq m}, Bb_{\leq n})$ consists of collections $k$-linear morphisms $h(A, A') : B^+a_{\leq m}(A, A') \to Bb_{\leq n}(f_1(A), f_2(A'))$ such that $h = h(A, A')_{A,A'}$ satisfies the following identity for $u \in (B^+a)_{\leq m}$

$$\Delta(h(u)) = \sum_{(u)} (f_2 \otimes h + h \otimes f_1)(u_{(1)} \otimes u_{(2)}).$$

where (using the Sweedler notation) $\Delta(u) = \sum_{(u)} u_{(1)} \otimes u_{(2)}$. It follows that $h \in \Sigma \text{Hom}(f_1, f_2)$ is determined by the “Taylor coefficients”

$$h_k : \Sigma a(A_{k-1}, A_k) \otimes \Sigma a(A_{k-2}, A_{k-1}) \otimes \cdots \otimes \Sigma a(A_0, A_1) \to \Sigma b(f_1(A_0), f_2(A_k))$$

for $1 \leq k \leq m$ as well as for each $A \in \text{Ob}(a)$ an element $h_0(A) := h_0(\cdot)_A \in \Sigma b(f_1(A), f_2(A))$ and the corresponding coderivation is given by

$$h = \sum f_{2,j} \otimes \cdots \otimes f_{2,j_1} \otimes h_k \otimes f_{1,i_1} \otimes \cdots \otimes f_{1,i_1}$$

where the right-hand side is restricted to terms which have $\leq m$ arguments. Note that $h$ sends $(B^+a)_{\leq m}$ to $(Bb)_{\leq m+1}$ (as the $f$’s take at least one argument but $h_0$ takes zero arguments). So since $m \leq n - 1$, $h$ is indeed well defined.

**Definition 5.5** (The differential on $A_m(a, b)$). If $m \leq n - 1$ and $h \in \Sigma \text{Hom}(f_1, f_2)$ then $b_1(h) = [b, h] = b \circ h - (-1)^{|h|} \circ b \circ h$. Concretely

$$b_1(h)_k = \sum_{\sum i_j + \sum j_i + k = k} b_{p+q+1} \circ (f_{2,j} \otimes \cdots \otimes f_{2,j_1} \otimes h_1 \otimes f_{1,i_1} \otimes \cdots \otimes f_{1,i_1})$$

$$- (-1)^{|h|} \sum_{a_0 + a_1 + l = k} h_{1+a_0+a_1} \circ (id_{\otimes a_0} \otimes b_l \otimes id_{\otimes a_1})$$

**Definition 5.6** (The higher multiplications on $A_m(a, b)$). Assume we have morphisms

$$f_0 \xrightarrow{h_1} f_1 \xrightarrow{h_2} \cdots \xrightarrow{h_k} f_k$$

represented by

$$h_j \in \text{coDer}_{f_{j-1}, f_j}(B^+a_{\leq m}, Bb_{\leq n})$$

and assume $2 \leq k \leq n - m$. Then we put

$$h_k \cup \cdots \cup h_1 = \sum f_{k,1,j_1} \otimes \cdots \otimes f_{k,j_k} \otimes h_{1,a_1} \otimes f_{1,1,j_1} \otimes h_{1,a_1} \otimes \cdots \otimes f_{1,j_1} \otimes f_{0,j_0} \otimes \cdots \otimes f_{0,j_1}$$

and $b_k(h_k, \ldots, h_1) = (b \circ (h_k \cup \cdots \cup h_1))$ where $(-)_k$ denotes Taylor coefficients.

Note that on the right-hand side of (5.6) the $f$’s take at least one argument but the $h$’s may take zero arguments. It follows that $h_k \cup \cdots \cup h_1$ maps $B^+a_{\leq m}$ to $Bb_{\leq m+k}$, and hence by the hypothesis $k \leq n - m$ is
a well defined element of \( \text{Hom}(B^+a_{\leq m}, Bb_{\leq n}) \). It is however not a coderivation. Instead it is inductively characterized by the following property for \( u \in (B^+a)_{\leq m} \) (using again the Sweedler notation)

\[
\Delta((h_k \cup \cdots \cup h_1)(u)) = \sum_{(u)} \left( f_k \otimes (h_k \cup \cdots \cup h_1) + (h_k \cup \cdots \cup h_1) \otimes f_1 \right) + \sum_{1 \leq j \leq k} \left( h_k \cup \cdots \cup h_{j+1} \right) \otimes (h_j \cup \cdots \cup h_1) \right)(u(1) \otimes u(2))
\]

One checks

**Lemma 5.7.** The collection of maps \((b_i)_{i=1, \ldots, n-m}\) makes \(A_m(a, b)\) into an \(A_{n-m}\)-category.

5.4. Homotopies and homotopic functors. Let \(a, b\) be \(A_n\)-categories, let \(1 \leq m \leq n-1\) (thus \(n \geq 2\)) and let \(h \in \Sigma Z^1\text{Der}(f_1, f_2)(B^+a_{\leq m}, Bb_{\leq n})\) and \([b, h] = 0\). Let \((h_k)_{k=0, \ldots, m}\) be the Taylor coefficients of \(h\). Specializing (5.5) to \(k = 0, 1\) we find that \(h_0(0) \in (\Sigma \text{C}(f_1, f_2))^{-1} = b(f_1, f_2)A_0\) satisfies \(d(h_0(0)) = 0\) and

\[
b_1b_1 + b_2b_0(h_0 \otimes f_1 + f_2 \otimes h_0) + h_1b_1 = 0
\]

Evaluating this on \(st \in a(A, B)\) we find

(5.7) \[
b_1(h_1(st)) + b_2(h_0(st), f_1(st)) + (-1)^{|t|+1}b_2(f_2(st), h_0(0)) + h_1(b_1(st)) = 0
\]

Put \(h_0(0) = sh_1(t)\). Using the usual sign convention \(h_1(st) = -sh_1(t)\), etc...together with (5.1) this may be rewritten as

\[
m_1(h_1(t)) + m_2(h_0, f_1(t)) + (-1)^{|t|+1}(-1)^{|t|}m_2(f_2(t), h_0(0)) + h_1(m_1(t)) = 0
\]

So we find in particular that \(H^*(h_0)\) defines a natural transformation \(H^*(f_1) \to H^*(f_2)\).

**Definition 5.8.** Let \(h, f_1, f_2\) be as above but assume \(n \geq 3\). We say that \(h\) is a homotopy \(h : f_1 \to f_2\) if \(H^*(h_0)\) is a natural isomorphism, i.e. if for all \(A \in \text{Ob}(a)\), \(H^*(h_0, A) \in H^*(\text{C}(a)(A, A))\) is invertible. We say that \(f_1, f_2\) are homotopic if there exists a homotopy \(h : f_1 \to f_2\).

**Lemma 5.9.** Assume \(1 \leq m \leq n-3\). Then \(h : f_1 \to f_2\) is a homotopy if and only if \(H^*(f_1)\) is invertible in \(H^*(a, b)\) (the latter is a genuine category because of the restriction on \(m, n\)). In particular the relation of being homotopic is an equivalence relation.

**Proof.** We have \(\langle hh' \rangle_0 = h_0h_0'\). So if \(h\) is invertible then it is a homotopy. Assume now \(h_0\) is invertible. Consider the morphism of complexes

\[
S : A_m(a, b)(f_2, f_1) \to A_m(b, b)(f_2, f_2) : h' \mapsto m_2(h, h')
\]

Using an appropriate spectral sequence one finds that \(S\) is a quasi-isomorphism. Hence there exists \(h' \in Z^0A_m(a, b)(f_2, f_1)\) such that \(m_2(h, h') - id_{f_2}\) has zero image in \(H^*(A_m(a, b)(f_2, f_2))\).

5.5. Inverting quasi-equivalences. We prove some \(A_n\)-versions of results which are well-known in the \(A_\infty\)-setting (e.g. [7, Théorème 9.2.0.4]).

**Lemma 5.10.** Let \(a, b\) be \(A_n\)-categories for \(n \geq 3\) and let \(f : a \to b\) be an \(A_n\)-functor which is a quasi-equivalence. There exists an \(A_{n-1}\)-quasi-equivalence \(g : b \to a\) such that \(fg\) and \(id_b\) are homotopic. Moreover the quasi-inverse \(H^*(g_1)\) to \(H^*(f_1)\) may be chosen freely.
Proof. If \( A \) is an \( A \)-category then we define \( \tilde{a} \) as the DG-graph obtained from \( a \) by dividing out identities. I.e.

\[
\tilde{a}(A, B) = \begin{cases} 
    a(A, B) & \text{if } A \neq B \\
    a(A, A)/k \text{id}_A & \text{if } A = B
\end{cases}
\]

Note that formally \( f \) is a cofunctor \( B \alpha \rightarrow B \beta \) such that \([b, f] = 0\). Likewise \( g \) should be a cofunctor \( B \beta \rightarrow B \delta \) satisfying \([b, g] = 0\) and the homotopy \( h : fg \rightarrow \text{id}_b \) should be an element of \( \text{coDer}_{f, \text{id}_b}(B^{+}B \delta_{m-1}^{+}, B \delta_{m}) \) of degree \(-1\) satisfying \([b, h] = 0\) such that \( H^{*}(h_{0}) \) is a natural isomorphism \( H^{*}(fg) \rightarrow \text{id}_{H^{*}(b)} \).

We will construct \( g \) and \( h \) step by step. The existence of \( g_{1} \) and \( h_{0}, h_{1} \) follows simply from the fact that \( f \) is a quasi-equivalence: we choose a unit preserving graded graph homomorphism \( g_{1} : b \rightarrow a \) commuting with differentials such that there is a natural isomorphism \( H^{*}(f_{1})H^{*}(g_{1}) \rightarrow \text{id}_{H^{*}(b)} \). We choose \( h_{0} : (Bb)_{0} \rightarrow b \) in such a way that this natural isomorphism is of the form \( H^{*}(h_{0}) \) and then we choose \( h_{1} \) such that the equation (5.7) holds.

Assume that for \( 1 \leq m < n - 1 \) that we have constructed a cofunctor \( g_{\leq m} : (Bb)_{\leq m} \rightarrow (Bb)_{\leq m} \) satisfying \([b, g_{\leq m}] = 0\) and a homotopy \( h_{\leq m} : f g_{\leq m} \rightarrow \text{id}_{b} \). We will extend the maps \((g_{\leq m}, h_{\leq m})\) to maps \((g_{\leq m+1}, h_{\leq m+1})\) with the same properties.

As a first approximation we extend \( g_{\leq m}, h_{\leq m} \) to respectively a cofunctor \( g_{\leq m+1} : Bb_{\leq m+1} \rightarrow Bb_{\leq m+1} \) and a \((f g_{\leq m+1}, \text{id}_{b})\)-coderivation \( h_{\leq m+1} : (B^{+}B)_{\leq m+1} \rightarrow Bb_{m+1} \) by setting \( g_{m+1}, h_{m+1} : (\Sigma b)_{\leq m+1} \rightarrow \Sigma a \) equal to zero (see (5.2) for the definition of \( (\Sigma b)_{\leq m+1} \)). Here \( \pi = [b, g_{\leq m+1}] \) is zero on \((\Sigma b)_{\leq m+1} \), \( i \leq m \) and hence it may be regarded as a map \((\Sigma b)_{\leq m+1} \rightarrow \Sigma a \). Moreover \( 0 = [b, \pi] = [b_{1}, \pi] \). So \( \pi \) is closed for the \( b_{1} \)-differential and since \( f \pi = [b, f g_{\leq m+1}] \) is zero on cohomology and \( f \) is a quasi-isomorphism, \( \pi \) is equal to zero in cohomology as well. In other words, there exists \( \delta_{m+1} : b_{\leq m+1} \rightarrow a \) such that \( \pi = [b_{1}, \delta_{m+1}] \). We now replace \( g_{m+1} \) by \( g_{m+1} - \delta_{m+1} \). Then \([b, g_{\leq m+1}] = 0\). In other words \( g_{\leq m+1} \) is an \( A_{m+1} \)-morphism.

Put \( D = [b_{1}, h_{\leq m+1}] \) (see (5.5)). Then \( D \) is a \((f g_{\leq m+1}, \text{id}_{b})\)-coderivation \((B^{+}b)_{\leq m+1} \rightarrow Bb_{\leq m} \) which is zero on \((Bb)_{\leq m} \) and hence it can be considered as a map \((\Sigma b)_{\leq m+1} \rightarrow \Sigma b \). Hence we have

\[
[b_{1}, D] = [b_{1}, D] = 0
\]

We will now try to choose \( \sigma_{m+1} : (\Sigma b)_{\leq m+1} \rightarrow \Sigma a, \tau_{m+1} : (\Sigma b)_{\leq m+1} \rightarrow \Sigma b \) such that for \( g_{m+1} = g_{m+1} + \sigma_{m+1}, h'_{m+1} = h_{m+1} + \tau_{m+1} \), \( g'_{m+1} = g_{m+1} + \sigma_{m+1} \) for \( i \leq m \) we have \([b, g'_{\leq m+1}] = 0, [b', h'_{\leq m+1}] = 0 \) where here \([b', h'] \) is the differential (5.5) computed with \( f_{1} = f g_{\leq m+1} \) and \( f_{2} = \text{id}_{b} \). The conditions we have to satisfy are

\[
0 = [b, g'_{\leq m+1}] = [b_{1}, \sigma_{m+1}]
\]

\[
0 = [b', h'_{\leq m+1}] = D + b_{2} \circ (h_{0} \otimes f_{1} (g_{m+1} + \sigma_{m+1}))) + [b_{1}, \tau_{m+1}]
\]

We claim these equations have a solution. First note that (5.10) may be written as

\[
b_{2} \circ (h_{0} \otimes f_{1} \sigma_{m+1}) = -D - b_{2} \circ (h_{0} \otimes f_{1} g_{m+1}) \mod \text{im}[b_{1}, -]
\]

Recall that here we have \([b_{1}, D] = 0, b_{1} \circ h_{0} = 0 \) (see §5.4), \([b_{1}, f_{1} g_{m+1}] = 0 \). Hence if we have a solution \( \sigma_{m+1} \) to (5.9)(11) and we replace \( \sigma_{m+1} \) by \( \sigma_{m+1} + [b_{1}, s] \) then it is still a solution.

It follows we may combine (5.9)(11) into a single equation

\[
b_{2} \circ (h_{0} \otimes f_{1} \sigma_{m+1}) = -D - b_{2} \circ (h_{0} \otimes f_{1} g_{m+1})
\]

in

\[
H^{*}(\text{Hom}(\Sigma b)_{\leq m+1}, b) = \text{Hom}(\Sigma H^{*}(b)_{\leq m+1}, \Sigma H^{*}(b))
\]
where $\overline{?}$ denotes cohomology classes or actions on cohomology. Using the fact that $f_1 = H^*(f_1)$ is an equivalence and $H^*(h_0)$ is a natural isomorphism one easily sees that (5.12) has a (unique) solution. □

We will need the following variant of Lemma 5.10 which is proved in a similar way.

**Lemma 5.11.** Let $a, b$ be $A_n$-categories for $n \geq 3$ and let $f : a \to b$ be a fully faithful $A_n$-functor which is also a quasi-equivalence. Then there exists an $A_{n-1}$-quasi-equivalence $g : b \to a$ such that $f g$ and $\text{id}_a$ are homotopic and such that $g f = \text{id}_a$. Moreover the quasi-inverse $H^*(g_1)$ to $H^*(f_1)$ may be chosen freely.

### 5.6. The category Free($a$).

**Definition 5.12.** Given an $A_n$-category $a$, Free($a$) is obtained from $a$ by formally adding finite (possibly empty) direct sums and shifts of objects in $a$, i.e. an object of Free($a$) is given by

\[(5.13) \quad A = \bigoplus_{i \in I} \Sigma^a A_i\]

where $A_i \in \text{Ob}(a)$, $a_i \in \mathbb{Z}$, $|I| < \infty$. We allow $|I| = \emptyset$. Morphisms in $a$ are defined as

\[\text{Free}(a)(\bigoplus_i \Sigma^a A_i, \bigoplus_j \Sigma^b B_j) = \bigoplus_i \Sigma^{a_i-b_j} a(A_i, B_j)\]

An element $f \in a(A, B)$ considered as an element of Free($a$)($\Sigma^a A$, $\Sigma^b B$) will be written as $\sigma^{b-a} f$ such that $|\sigma^{b-a} f| = |f| - (b - a)$.

If $a$ is an $A_n$-category we can then make Free($a$) into an $A_n$-category. We need to define the higher compositions between morphisms between objects of the form $\Sigma^a A$ (the case of more complicated objects is done by linear extension). So if we have we have maps in $a$:

\[A_0 \overset{f_1}{\to} A_1 \overset{f_2}{\to} \cdots \overset{f_n}{\to} A_n\]

and corresponding maps in Free($a$)

\[\Sigma^a A_0 \overset{\sigma^{a_1-a_0} f_1}{\to} \Sigma^a A_1 \overset{\sigma^{a_2-a_1} f_2}{\to} \cdots \overset{\sigma^{a_n-a_{n-1}} f_n}{\to} \Sigma^a A_n\]

then

\[b_n(s a^{a_{n-1}} f_n, \ldots, s a^{a_2-a_1} f_2, s a^{a_1-a_0} f_1) = \pm s a^{a_{n-1}} b_n(s f_n, \ldots, s f_2, s f_1)\]

where the sign is determined by the usual Koszul sign convention (used with the rule $ss = -ss$).

The $A_n$-category Free($a$) is equipped with an strict $A_n$-endo functor $\Sigma$ such that on objects we have

\[(5.14) \quad \Sigma (\bigoplus_i \Sigma^a A_i) = \bigoplus_i \Sigma^{a+1} A_i\]

and on morphisms $\Sigma$ is given by $\Sigma(\sigma^a f) = (-1)^a \sigma^a f$ for $f$ a morphism in $a$. We will call $\Sigma$ the shift functor on Free($a$). Likewise Free($a$) is equipped with an (associative) operation $\oplus$ with an obvious definition. We will call it the “direct sum”. Finally if $I = \emptyset$ in (5.13) the resulting object is denoted by $0$ and is called the “zero object”.

### 6. TRUNCATED TWISTED COMPLEXES

From now on let $a$ be an $A_n$-category.
6.1. **Higher cone categories.** Let \( a^{\oplus m} \) be the graded graph whose objects are formal direct sums of precisely \( m \) objects in \( a \).

(6.1) \[
A = A_0 \oplus A_1 \oplus \ldots \oplus A_{m-1}.
\]

Morphisms are given by

(6.2) \[
a^{\oplus m}(A, B) = \oplus_{i,j=0}^{m-1}(A_i, B_j).
\]

We extend the higher operations on \( a \) linearly to \( a^{\oplus m} \) so that \( a^{\oplus m} \) becomes an \( A_n \)-category.

**Remark 6.1.** Below we usually think of objects in \( a^{\oplus m} \) as column vectors and similarly of morphisms in \( a^{\oplus m} \) as matrices acting on those column vectors.

**Definition 6.2 (Higher cone categories).** Assume \( m \leq n+1 \). The graded graph \( a^{*m} \) is defined as follows.

- Objects are given by couples \((A, \delta_A)\) such that \( A \in \text{Ob}(a^{\oplus m}) \) and \( \delta_A \in a^{\oplus m}(A, A)_1 \) is a “Maurer-Cartan element” with strictly lower triangular matrix, i.e. it satisfies

(6.3) \[
\sum_{i \leq m-1} b_i(s_{\delta_A}, \ldots, s_{\delta_A}) = 0
\]

- Morphisms are given by

(6.4) \[
a^{*m}((A, \delta_A), (B, \delta_B)) = a^{\oplus m}(A, B)
\]

**Lemma 6.3.** Assume \( m \leq n+1 \). The graded graph \( a^{*m} \) has the structure of an \( A^{[\frac{n-m+1}{m}]} \)-category with higher multiplications given by

(6.5) \[
b_{a^{*m},i}(s_{g_i}, \ldots, s_{g_1}) = \sum_{l_{i0}, \ldots, l_{i1}} b_{a^{\oplus m},i}(s_{\delta_{l_{i0}}}, \ldots, s_{\delta_{l_{i1}}}, s_{g_i}, s_{\delta_{l_{i-1}}}, \ldots, s_{\delta_{l_{i-2}}}, \ldots, s_{\delta_{l_2}}, \ldots, s_{\delta_{l_1}}, s_{g_1}, s_{\delta_{l_0}}, \ldots, s_{\delta_0})
\]

for any set

\[
(B_0, \delta_0) \xrightarrow{\xi_1} (B_1, \delta_1) \xrightarrow{\xi_2} \ldots \xrightarrow{\xi_i} (B_i, \delta_i).
\]

of \( i \leq \lceil \frac{n-m+1}{m} \rceil \) composable arrows in \( a^{*m} \).

**Proof.** We need to check \( b_{a^{*m}} \circ b_{a^{*m}} = 0 \) on \( i \) composable arrows for \( i \leq \lceil \frac{n-m+1}{m} \rceil \) as well as the correct behavior of identities. We will concentrate on the first condition as it is the most interesting one. As we will use similar facts several times below we present the argument in some detail.

If we expand \( (b_{a^{*m}} \circ b_{a^{*m}}) \), then it becomes the sum of multilinear expressions evaluated on lists of arguments of the form

(6.6) \[
s_{\delta_{l_{i0}}}, \ldots, s_{\delta_{l_{i1}}}, s_{g_i}, s_{\delta_{l_{i-1}}}, \ldots, s_{\delta_{l_{i-2}}}, \ldots, s_{\delta_{l_2}}, \ldots, s_{\delta_{l_1}}, s_{g_1}, s_{\delta_{l_0}}, \ldots, s_{\delta_0}
\]

The crucial point is that those multilinear expression are obtained by linear expansion of the corresponding expressions evaluated on composable arrows in \( a \). Now for each element \((A, \delta_A) \in a^{*m}\), the Maurer-Cartan element \( \delta_A \) is a strictly lower triangular \( m \times m \)-matrix and hence such extended expressions are zero on (6.6) whenever one of the \( l_j \) is \( \geq m \).

By the assumption

\[
i \leq \left\lceil \frac{n-m+1}{m} \right\rceil
\]
we obtain that the length of the relevant lists of arguments in (6.6) is
\[ \leq (m - 1)(i + 1) + i \]
\[ = mi + m - 1 \]
\[ \leq m \left[ \frac{n - m + 1}{m} \right] + m - 1 \]
\[ \leq n - m + 1 + m - 1 \]
\[ = n \]

Now the condition \( b_\infty \circ b_\infty = 0 \) becomes \( b_\infty \circ b_\infty = 0 \) when evaluated on lists of \( \leq n \) arguments. This holds since \( a_\infty \) is an \( A_\infty \)-category. □

Below we call \( a^{s}m \) a higher cone category. This is motivated by Definition 6.8 below.

**Lemma 6.4** (Functoriality of \( \ast \)). Given \( A_\infty \)-categories \( a \) and \( b \) and \( t \leq m + 1 \leq n + 1 \), we obtain a strict \( A_p \)-functor

\[ \ast': A_m(a, b) \to A_{\lfloor (m+1)/t \rfloor}(a^{s}, b^{s}) \]

for \( p = \lfloor (n + 1)/t \rfloor - \lfloor (m + 1)/t \rfloor \). Moreover \( \ast' \) is strictly compatible with the compositions

\[ A_m(b, c) \times A_m(a, b) \to A_m(a, c). \]

**Proof.** Since we are defining a strict functor we only need to define \( (\ast')_1 \). We will write \( (\ast')_1(\ast') \).

First of all we define the functor on “objects”. For an element \( f \in \text{Ob}(A_m(a, b)) \) and \( (A, \delta_A) \in \text{Ob}(a^{s}) \) define

\[ f^{s}\ast(A, \delta_A) = (f(A), \sum_{i \in \mathbb{Z}} f(s\delta_A^1, \ldots, s\delta_A^i)) \]

where \( f \) is understood to be extended linearly to direct sums. For a sequence of composable arrows

\[ (A_0, \delta_0) \xrightarrow{a_1} (A_1, \delta_1) \xrightarrow{a_2} \cdots \xrightarrow{a_d} (A_d, \delta_d) \]

put

\[ (f^{s}\ast)_d(sa_d, \ldots, sa_1) = \sum f_d + i_0 + \cdots + i_d(s\delta_d^0, sa_d, s\delta_d^{i_0} \cdots, sa_1, s\delta_0^i). \]

To show that \( \ast' \) sends an \( A_m \)-functor to an \( A_{\lfloor (m+1)/t \rfloor} \)-functor (i.e. an element of \( \text{Ob}(A_{\lfloor (m+1)/t \rfloor}(a^{s}, b^{s})) \)), one proceeds in the same way as in the proof of Lemma 6.3.

Now we define \( (\ast')_1 \) on Hom-spaces in \( A_m(a, b) \). Given \( f, g \in A_m(a, b) \) and \( h \in A_m(a, b)(f, g) \) we define \( h^{s}\ast \in \text{Hom}(f^{s}, g^{s}) \) as follows: for a sequence of composable arrows as in (6.7) we have

\[ (h^{s}\ast)_d(sa_d, \ldots, sa_1) = \sum h_d + i_0 + \cdots + i_d(s\delta_d^0, sa_d, s\delta_d^{i_0} \cdots, sa_1, s\delta_0^i). \]

One verifies that \( (\ast')_1 \) commutes with the higher operations on \( A_m(a, b) \) and \( A_{\lfloor (m+1)/t \rfloor}(a^{s}, b^{s}) \) (see Lemma 5.7) and hence defines a strict functor. It is an \( A_p \)-functor since \( A_{\lfloor (m+1)/t \rfloor}(a^{s}, b^{s}) \) is an \( A_p \)-category by Lemma 6.3 and Lemma 5.7. The strict compatibility with compositions is also a standard verification. □
6.2. **Truncated twisted complexes.** In the $A_p$-category setting, untruncated twisted complexes are not well behaved as they form only a graded graph. Indeed even the definition of the differential on morphisms between twisted complexes involves higher operations of unbounded arity. Therefore in this section we introduce *truncated twisted complexes* over an $A_n$-category. In this case the resulting object is still an $A_p$-category for some $p$, although $p$ is much smaller than $n$.

**Definition 6.5** (Truncated twisted complexes). Assume $m \leq n$. We define the truncated twisted complexes over $a$ as

$$\text{Tw}_{\leq m}a = \text{Free}(a)^{s_{m+1}}$$

The map

$$(A, \delta_A) \mapsto (A \oplus 0, (\delta_A, 0))$$

defines a fully faithful functor $\text{Tw}_{\leq m}a \to \text{Tw}_{\leq m+1}a$ which we will treat as an inclusion. With this convention we write $\text{Tw}a$ for $\bigcup_m \text{Tw}_{\leq m}a$ in case $a$ is an $A_{\infty}$-category. In a similar vein we define the fully faithful functor $\Phi : a \to \text{Tw}_{\leq m}a : A \mapsto (A \oplus 0 \oplus \cdots, 0)$ which again we will treat as an inclusion.

From Lemma 6.3 we obtain

**Lemma 6.6.** Assume $m \leq n$. The category of truncated twisted complexes $\text{Tw}_{\leq m}a$ has a structure of an $A_{\frac{m}{n+1}}$-category.

**Lemma 6.7** (Functoriality of Tw). Let $F : a \to b$ be an $A_m$-functor between two $A_n$-categories with $a \leq m \leq n$. Then we obtain a corresponding $A_{\frac{m}{n+1}}$-functor

$$\text{Tw}_{\leq a}F : \text{Tw}_{\leq a}(a) \to \text{Tw}_{\leq a}(b).$$

Moreover $\text{Tw}_{\leq a}(-)$ is strictly compatible with compositions of $A_n$-functors.

**Proof.** This follows immediately from Lemma 6.4. □

6.3. **Distinguished triangles.**

**Definition 6.8.** Assume $f : A \to B$ is closed morphism in $a$ of degree zero. Then $C(f)$ is the object $(\Sigma A \oplus B, \delta_{C(f)}) \in \text{Tw}_{\leq 1}a$ such that

$$\delta_{C(f)} = \begin{pmatrix} 0 & 0 \\ \sigma^{-1} f & 0 \end{pmatrix}$$

(recall that we write objects as column vectors and morphisms as matrices - see Remark 6.1).

**Definition 6.9.** Let $f : A \to B$ be a morphism in $Z^0a$. The associated **standard distinguished triangle** $\delta_f$ in $\text{Tw}_{\leq 1}a$ is given by

$$\begin{array}{ccc}
A \xrightarrow{f} B \xrightarrow{i} (C(f), \delta_{C(f)}) & \xrightarrow{p} & A \\
& \langle l \rangle & \\
\end{array}$$

where

$$i = \begin{pmatrix} 0 \\ \text{id}_B \end{pmatrix} \quad p = (\sigma^{-1} \text{id}_A \quad 0)$$

The image of $\delta_f$ in $H^0(\text{Tw}_{\leq 1}a)$ is written as $\delta_f$. It is also called a standard distinguished triangle.

**Definition 6.10.** Let $a$ be an $A_n$-category with $n \geq 7$. A triangle in $H^*(a)$ is said to be **distinguished** if its image under $H^*(\Phi)$ is isomorphic to a standard distinguished triangle in $H^*(\text{Tw}_{\leq 1}a)$.

From this definition we immediately obtain:
Theorem 6.11. Let \( \rho : a \rightarrow b \) be an \( A_m \)-functor between \( A_n \)-categories for \( m \geq 5, n \geq 7 \). Then \( H^*(\rho) \) preserves distinguished triangles.

Proof. It is clear that there is a commutative diagram

\[
\begin{array}{ccc}
a & \xrightarrow{\Phi} & Tw_{\leq 1} \ a \\
| \ & \Phi & \downarrow \ & \Phi \\
b & \xrightarrow{\rho} & Tw_{\leq 1} \ b \\
\end{array}
\]

By Lemma 6.6 \( Tw_{\leq 1} a \) and \( Tw_{\leq 1} b \) are \( A_3 \)-categories and by Lemma 6.7, \( Tw_{\leq 1} \rho \) is an \( A_2 \)-functor. Hence \( H^*(Tw_{\leq 1} \rho) \) is a graded functor (see §5.1). One checks \( H^*(Tw_{\leq 1} \rho)(\tilde{\delta}_f) = \delta_{\rho}(f) \). This implies what we want. \( \square \)

7. DG-CATEGORIES

7.1. Generalities. Recall that a DG-category is an \( A_{\infty} \)-category such that \( m_i = 0 \) for \( i \geq 3 \). It that case \( Tw a \) is also a DG-category. We recall the following definition.

Definition 7.1. [3] A DG-category is pre-triangulated if the DG-functor \( \Phi : a \rightarrow Tw a \) is a quasi-equivalence.

The main result concerning pre-triangulated DG-categories is

Theorem 7.2. [3] If \( a \) is pre-triangulated then \( H^*(a) \), when equipped with distinguished triangles as in Definition 6.10, is triangulated.

Proof. Assume first that \( a \) is a general DG-category. \( Tw a \) is equipped with a natural cone functor \( C(f) \) and a notion of standard triangles \( \delta_f \) for any closed map \( f : A \rightarrow B \):

\[
A \xrightarrow{f} B \xrightarrow{j} C(f) \xrightarrow{\rho} A.
\]

A triangle in \( Tw a \) is called distinguished if it is isomorphic to a standard triangle. In [3] it is proved that \( H^*(Tw a) \) is triangulated when equipped with this class of distinguished triangles. If \( a \) is pre-triangulated then \( H^*(a) \) inherits the triangulated structure from \( H^*(Tw a) \). We have to prove that the distinguished triangles are the same as those in Definition 6.10. Assume that

\[
\tilde{\delta} : A \xrightarrow{f} B \xrightarrow{j} C(\tilde{\delta}) \xrightarrow{(1)} A
\]

is a triangle in \( H^*(a) \) distinguished in the sense of [3], i.e. \( \Phi(\tilde{\delta}) \) is distinguished in \( H^*(Tw a) \). Now \( \delta_{\Phi(f)} \in H^*(Tw_{\leq 1} a) \) is a distinguished triangle in \( H^*(Tw a) \) which has the same base as \( \delta_f \). By the axioms for triangulated categories we conclude that \( \Phi(\tilde{\delta}) \cong \delta_{\Phi(f)} \). Hence \( \tilde{\delta} \) is distinguished in the sense of Definition 6.10. The opposite direction is similar. \( \square \)

7.2. Some small DG-categories.

Definition 7.3. Let \( n \geq 0 \). Then \( I_n \) is the DG-category with objects \( (x_i)_{i=0}^n \) such that

\[
I_n(x_i, x_j) = \begin{cases} 
ka_{ij} & \text{if } i < j \\
k\delta_{x_i} & \text{if } i = j \\
0 & \text{otherwise}
\end{cases}
\]
with $|a_{ij}| = 0$, $a_j a_{ij} = a_{ij}$ and $d a_{ij} = 0$. We will write $a_i = a_{i,i+1}$ for $i = 0, \ldots, n - 1$.

**Lemma 7.4.** $\text{Tw}_{\leq 1} I_n$ is pre-triangulated.

**Proof.** As $\text{Tw} I_n$ is pre-triangulated [3] it is sufficient to prove that $H^*(\text{Tw}_{\leq 1} I_n) \to H^*(\text{Tw} I_n)$ is essentially surjective. This is essentially [13, Proposition 7.27]. For the convenience of the reader we repeat the argument. The Yoneda embedding realizes $H^*(\text{Tw} I_n)$ as the bounded derived category $D^b(\text{rep}(I_n))$ of the representations of $I_n$, viewed as quiver. Since $\text{rep}(I_n)$ is a hereditary category every object in $D^b(\text{rep}(I_n))$ is the direct sum of its (shifted) cohomology objects which are in $\text{rep}(I_n)$. Moreover every object in $\text{rep}(I_n)$ has projective dimension one and so it is isomorphic to a single cone of objects in $\text{Free}(I_n)$. In other words it is in the essential image of $H^*(\text{Tw}_{\leq 1} I_n)$.

**Remark 7.5.** Assume $n = 0$. Then $\text{rep}(I_0)$ has global dimension zero and we have in fact that $\text{Free}(I_0) = \text{Tw}_{\leq 0} I_0$ is pre-triangulated.

8. **PRE-TRIANGULATED $A_n$-CATEGORIES**

From now on let $\mathfrak{a}$ be an $A_n$-category. The purpose of this section is to define what it means for $\mathfrak{a}$ to be pre-triangulated and to show that this definition implies that $H^*(\mathfrak{a})$ is triangulated.

**Definition 8.1.** An $A_n$-category $\mathfrak{a}$, with $n \geq 7$, is said to be pre-triangulated if the inclusion $\mathfrak{a} \xrightarrow{\Phi} \text{Tw}_{\leq 1} \mathfrak{a}$ is a quasi-equivalence.

**Remark 8.2.** The lower bound $n \geq 7$ comes from the fact that we want $H^*(\text{Tw}_{\leq 1} \mathfrak{a})$ to be an honest category. This happens when $\text{Tw}_{\leq 1} \mathfrak{a}$ is an $A_3$-category. For this to be true $\mathfrak{a}$ needs to be at least an $A_3$-category by Lemma 6.6.

**Theorem 8.3.** Let $\mathfrak{a}$ be a pre-triangulated $A_n$-category for $n \geq 13$. When equipped with the collection of distinguished triangles as in Definition 6.10, $H^*(\mathfrak{a})$ is a triangulated category.

**Proof.** Here is the “strategy”: we have to prove that $H^*(\mathfrak{a})$ satisfies TR0-TR4 as in §4.4. For the TR1-TR4 axioms we will translate their input into a suitable $A_n$-functor $\mu : I_m \to \mathfrak{a}$, for $m \leq 2$, which is then extended to an $A_{[(n-1)/2]}$-functor $\text{Tw}_{\leq 1} \mu : \text{Tw}_{\leq 1} I_m \to \text{Tw}_{\leq 1} \mathfrak{a}$. Then we use that $\text{Tw}_{\leq 1} I_m$ is pre-triangulated by Lemma 7.4 and hence in particular $H^*(\text{Tw}_{\leq 1} I_m)$ is triangulated by Theorem 7.2. Roughly speaking we then transfer the output of the TR1-TR4-axioms for $H^*(\text{Tw}_{\leq 1} I_m)$ to $H^*(\mathfrak{a})$ by using Theorem 6.11.

To accomplish the last step we will pick an $A_{[(n-1)/2]}$-functor $\pi : \text{Tw}_{\leq 1} \mathfrak{a} \to \mathfrak{a}$, for $p = [(n - 3)/2]$, which is a homotopy inverse to $\Phi$ such that $\pi \Phi$ is the identity (see Lemmas 6.6, 5.11). In particular we have that $H^*(\Phi)$ and $H^*(\pi)$ are quasi-inverses to each other. Since $n \geq 13$, $\text{Tw}_{\leq 1} \mu$ is at least an $A_{[(n-1)/2]}$-functor and $\pi$ is at least an $A_{[(n-3)/2]}$-functor. So $H^*(\pi \text{Tw}_{\leq 1} \mu)$ preserves distinguished triangles by Theorem 6.11. To avoid making some arguments needlessly cumbersome we will in fact also use that $H^*(\text{Tw}_{\leq 1} \mu)$ preserves standard distinguished triangles and that $H^*(\pi)$ sends a standard distinguished triangle in $H^*(\text{Tw}_{\leq 1} \mu)$ to a distinguished triangle in $H^*(\mathfrak{a})$. The latter follows easily from the fact that $H^*(\pi)$ is a quasi-inverse to $H^*(\Phi)$. Note that the intermediate category $\text{Tw}_{\leq 1} \mathfrak{a}$ may be only an $A_{[(n-1)/2]}$-category so, with our current definitions, we cannot talk about distinguished triangles in $H^*(\text{Tw}_{\leq 1} \mathfrak{a})$.

TR0  Like $\text{Free}(\mathfrak{a})$ (see §5.6), $\text{Tw}_{\leq 1} \mathfrak{a}$ is equipped with canonical operations $\Sigma$ and $\Theta$. These descend to operations on $H^*(\text{Tw}_{\leq 1} \mathfrak{a})$ which one easily checks to be to be the categorical direct sum and shift functor. Since $H^*(\mathfrak{a}) \to H^*(\text{Tw}_{\leq 1} \mathfrak{a})$ is an equivalence, the direct sum and shift functor defined on $H^*(\text{Tw}_{\leq 1} \mathfrak{a})$ descend to $H^*(\mathfrak{a})$.

---

5We could have eliminated this minor technical complication by simply requiring $n \geq 15$. 
TR1 First we note that the triangle

$$A \xrightarrow{id_A} A \xrightarrow{0} A$$

is distinguished. Indeed: the functor $\mu : I_0 \to a : x_0 \mapsto A$ extends to a functor $\mu : \TW_{\leq 1} I_0 \to \TW_{\leq 1} a$ and (8.1) is the image under $H^*(\pi \TW_{\leq 1} \mu)$ of the distinguished triangle in $H^*(\TW_{\leq 1} I_0)$ (which satisfies TR1)

$$x \xrightarrow{id_a} x \xrightarrow{0} 0 \xrightarrow{(1)} x$$

Now we prove the second part of the TR1 conditions: the existence of distinguished triangles with a given base. Consider a map $A \xrightarrow{f} B$ in $H^*(a)$ and put $\tilde{\delta} = H^*(\pi)(\tilde{\delta}_f)$. Since $\tilde{\delta}_f$ is a standard distinguished triangle in $\TW_{\leq 1} a$, $\tilde{\delta}$ is distinguished.

Finally, the fact that any triangle isomorphic to a distinguished triangle is distinguished follows immediately from Definition 6.10.

TR2 Let $\tilde{\delta}$ be a distinguished triangle in $H^*(a)$. Then there exists an isomorphism with a standard triangle $H^*(\Phi)(\tilde{\delta}) \cong \tilde{\delta}_f$ and hence in particular $\tilde{\delta} \cong H^*(\pi)(\tilde{\delta}_f) := \tilde{\delta}'$. There is a strict $A_n$-functor $\mu : I_1 \to a$ which sends $a_0$ to $f$ and $\tilde{\delta}_f$ is the image of $\tilde{\delta}_{a_0} \in H^*(\TW_{\leq 1} I_1)$ under the morphism $H^*(\TW_{\leq 1} \mu)$. Since $H^*(\TW_{\leq 1} I_1)$ satisfies TR2, the rotated versions of $\tilde{\delta}_{a_0}$ are distinguished in $H^*(\TW_{\leq 1} I_1)$ and we obtain rotated versions of $\tilde{\delta}'$ by applying $H^*(\pi \TW_{\leq 1} \mu)$ (note that a graded functor preserves suspensions and desuspensions). By TR1 the corresponding rotated versions of $\tilde{\delta}$ are also distinguished.

TR3 Suppose we have a diagram of distinguished triangles in $H^0(a)$

(8.2)

$$A \xrightarrow{f} B \xrightarrow{c} C \xrightarrow{(1)} A$$

$$A' \xrightarrow{f'} B' \xrightarrow{c'} C' \xrightarrow{(1)} A'$$

Up to composing with an isomorphism of triangles, we can assume that the two distinguished triangles in the diagram are standard distinguished triangles in $\TW_{\leq 1} a$ so that $C = C(f)$, $C' = C(f')$. Hence we have to construct the dotted arrow in

$$A \xrightarrow{f} B \xrightarrow{C(f)} A$$

$$A' \xrightarrow{f'} B' \xrightarrow{C(f')} A'$$

It is easy to give a formula for $w$. Alternatively one may lift the square on the left to an $A_n$-functor $I \otimes I \to a$ and then proceed by considering the induced functor $\TW_{\leq 1}(I \otimes I) \to \TW_{\leq 1} a$.

We will give instead a proof compatible with our “strategy”. By writing the solid square as a composition of 2 squares it is sufficient to consider the case in which either $u$ or $v$ is the identity.

\footnote{The reader will note that here the literal execution of our “strategy” is a bit uneconomical and that by Remark 7.5 we could have used $\TW_{\leq 0} I_0$.}
The two cases are similar so we will consider the first one. Now the diagram is

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{v} & & \downarrow{w} \\
A & \xrightarrow{f'w} & C(f')
\end{array}
\]

(8.3)

We may construct an \(A\)-morphism \(\mu : I_2 \rightarrow a\) such that \(\mu_1(a_0) = f, \mu_1(a_1) = v, \mu_1(a_1a_0) = f'w\) (note that we need a non-trivial \(\mu_2\) as \(vf\) is not necessarily equal to \(f'w\) in \(a\)). Inside \(H^*(\mathbb{T}_{\leq 1}I_2)\) we have the diagram

\[
\begin{array}{ccc}
x_0 & \xrightarrow{a_0} & x_1 \\
\downarrow{a_1} & & \downarrow{a_1} \\
x_0 & \xrightarrow{a_1a_0} & x_2 \\
\downarrow{a_1a_0} & & \downarrow{a_1a_0} \\
\end{array}
\]

where now the dotted arrow exists as \(H^*(\mathbb{T}_{\leq 1}I_2)\) satisfies TR3. Applying \(H^*(\mathbb{T}_{\leq 1}a)\) we obtain (8.3).

TR4 Since we have shown TR1-TR3, by [1, 1.1.6] it suffices to show that any composable pair of degree zero morphisms \(X \rightarrow Y \rightarrow Z\) in \(H^*(a)\) can be completed to an octahedron as in (4.1).

A composable pair of degree zero morphisms in \(H^*(a)\) can be lifted to an \(A\)-functor \(\mu : I_2 \rightarrow a\). The image of the octahedron in \(H^*(\mathbb{T}_{\leq 1}I_2)\) built on \(x_0 \xrightarrow{a_0} x_1 \xrightarrow{a_1} x_2\) under \(H^*(\pi \mathbb{T}_{\leq 1}a)\) is now the sought octahedron in \(H^*(a)\).

\[\blacksquare\]

9. Gluing \(A_n\)-categories

9.1. Bimodules. Let \(a, b\) be \(A_n\)-categories. An \(A_{n+1}\)-\(a\)-bimodule is collection of graded vector spaces \(M(A, B), A \in \text{Ob}(a), B \in \text{Ob}(b)\) together with a coderivation on \((B^* b \otimes M \otimes B^* a)_{\leq n+1}\) where the latter is regarded as a DG-(\(B^* a\))_\leq n-(\(B^* b\))_\leq n-bimodule. In other words, such a bimodule is equipped with higher operations of degree one

\[
b_M : \Sigma b(B_{p-1}, B_p) \otimes \cdots \otimes \Sigma b(B_{a+1}, B_{a+2}) \otimes M(A_{a}, B_{a+1}) \otimes \Sigma b(A_{a-1}, A_a) \otimes \cdots \otimes \Sigma b(A_0, A_1) \rightarrow M(A_0, B_p)
\]

for \((A_i)_{i} \in \text{Ob}(a), (B_i)_{j} \in \text{Ob}(b)\) for \(p \leq n + 1\) such that \(bb = 0\). In addition we require that the higher operations vanish on identities, when appropriate. If \(a = b\) then the identity \(A_n\)-a-bimodule is given by \(M(A, A') = a(A, A')\) and the higher operations are those of \(a\).

If \(a_1, a_2, b_1, b_2\) are \(A_n\)-categories, \(f_1 : a_1 \rightarrow b_1\) are \(A_n\)-functors and \(M\) is an \(A_{n+1}\)-\(b_2\)-\(b_1\)-bimodule then we write \(f_1Mf_2\) for the \(A_n\)-bimodule which is the pullback of \(M\) along \((f_1, f_2)\). For \(A_1 \in \text{Ob}(a_1), A_2 \in \text{Ob}(a_2)\) we have \(f_1Mf_2(A_1, A_2) = M(f_1(A_1), f_2(A_2))\) and the higher operations on \(f_1Mf_2\) are schematically given by the following formula for \(m \in f_1Mf_2(A_1, A_2)\)

\[
b_{f_1Mf_2}(..., m, ...) = \sum \pm b_M(f_2(...), ..., f_2(...), m, f_1(...), ..., f_1(2))
\]

(the sign is given by the Koszul convention). It is easy to see that \(f_1Mf_2\) is an \(A_{n+1}\)-bimodule. If \(f_1\) or \(f_2\) is the identity then we omit it from the notation.
9.2. The arrow category.

**Definition 9.1** (The arrow category). Let \(a, b\) be \(A_n\)-categories and let \(M\) be a \(b\text{-}a\)-\(A_n\)-bimodule. The arrow category \(c = a \xrightarrow{M} b\) has \(\text{Ob}(c) = \text{Ob}(b)\) \(\coprod\) \(\text{Ob}(a)\) and morphisms for \(B, B' \in \text{Ob}(b)\), \(A, A' \in \text{Ob}(a)\) given by \(c(A, A') = a(A, A'), c(B, B') = b(B, B')\) and \(c(A, B) = M(A, B), c(B, A) = 0\).

It is easy to see that \(a \xrightarrow{M} b\) becomes an \(A_n\)-category by combining the higher multiplications on \(a\), \(b\) and \(M\) (as in (9.1)).

Assume we have \(\\text{\(A_n\)}\)-categories \(a, b, a', b'\) and \(b\text{-}a\) and \(b\text{-}a'\) bimodules \(M\) and \(M'\). Below it will be convenient to consider the category \(A^n_m(a \xrightarrow{M} b, a' \xrightarrow{M'} b')\) of \(A_n\)-functors \(F : (a \xrightarrow{M} b) \to (a' \xrightarrow{M'} b')\) such that \(F(\text{Ob}(a)) \subset \text{Ob}(a'), F(\text{Ob}(b)) \subset \text{Ob}(b')\). It is easy to see that \(F\) contains the same data as \(A^n_m\)-functors \(F_a : a \to a', F_b : b \to b'\) together with a \(A_m\)-bimodule morphism \(F_M : M \to F_a M'_b\).

Sometime we will write \(F = (F_a, F_M, F_b)\).

9.3. The gluing category.

**Definition 9.2** (The gluing category). Assume \(n \geq 1\). Let \(a, b\) be \(A_n\)-categories and let \(M\) be a \(b\text{-}a\)-\(A_n\)-bimodule. The gluing category \(\coprod M b\) is the full graded subgraph of \((a \xrightarrow{M} b)^{\oplus 2}\) given by objects of the form \((A \oplus B, \delta)\) with \(A \in \text{Ob}(a)\) and \(B \in \text{Ob}(b)\) (note that \(\delta\) is simply an element of \(Z^1 M(A, B)\)).

**Lemma 9.3.** \(\coprod M b\) has the structure of an \(A_{n-1}\)-category with higher multiplications given by (6.5).

**Proof.** The proof is as in Lemma 6.3 except that now in the relevant argument lists in (6.6) we can have at most one \(\bar{\delta}\) as the \((g_j)_\bar{\delta}\) are now represented by lower triangular \(2 \times 2\)-matrices. \(\square\)

**Remark 9.4.** An alternative way of defining \(\coprod M b\) is as follows. Let \(J_1\) be defined like \(I_1\) (see §7.2) but that we put \(|\alpha_0| = 1\). Then \(\coprod M b\) may be identified with the full subcategory of \(A_1(J_1, a \xrightarrow{M} b)\) consisting of \(A_1\)-functors \(F : J_1 \to (a \xrightarrow{M} b)\) such that \(F(x_0) \in \text{Ob}(a), F(x_1) \in \text{Ob}(b)\). It then follows from Lemma 5.7 that \(\coprod M b\) is indeed an \(A_{n-1}\)-category.

The following will be our main result in this section.

**Theorem 9.5.** Assume that \(n \geq 13\), that \(a, b\) are pre-triangulated \(A_n\)-categories and that \(M\) is an \(A_n\)-\(b\text{-}a\)-bimodule. Then \(\coprod M b\) is a pre-triangulated \(A_{n-1}\)-category. Moreover the obvious fully faithful functors \(\varphi_a : H^*(a) \to H^*(\coprod M b), \varphi_b : H^*(b) \to H^*(\coprod M b)\) preserve distinguished triangles. If \(n \geq 14\) so that \(H^*(\coprod M b)\) is triangulated by Theorem 8.3 and Lemma 9.3 then \(\varphi_a, \varphi_b\) give rise to a semi-orthogonal decomposition

\[
H^*(\coprod M b) = \langle H^*(a), H^*(b) \rangle
\]

whose associated bimodule (see §1.3) is \(H^*(M)\).

The proof of this theorem requires some preparation. We start with:

**Proposition 9.6** (Functoriality of gluing). Assume we have \(A_n\)-categories \(a, b, a', b'\) and \(b\text{-}a\) and \(b'\text{-}a'\) bimodules \(M\) and \(M'\). Then for \(m \leq n\), there is a strict \(A_{n-m}\)-functor

\[
\phi : A^n_m(a \xrightarrow{M} b, a' \xrightarrow{M'} b') \to A^n_{n-m}(a \xrightarrow{M} b, a' \xrightarrow{M'} b').
\]

Moreover \(\phi\) is strictly compatible with compositions.
Proof. This is proved like Lemma 6.4 which also gives the relevant formulas (where we take into account that in this case at most one $\delta$ can appear in the relevant arguments lists in (6.6)).

Corollary 9.7. Let $3 \leq m \leq n - 3$ and let $a, b, a', b', M, M'$ be as in Proposition 9.6 and let $F \in A^m_n(a \rightarrow b, a' \rightarrow b')$. If $F$ is a quasi-equivalence then so is $\phi(F)$.

Proof. Note that $F$ is a quasi-equivalence if and only if $F_a, F_b$ are quasi-equivalences and $F_M$ is a quasi-isomorphism. By Lemma 5.10 we may choose an inverse $G \in A^m_{m-1}(a' \rightarrow b', a \rightarrow b)$ to $F$, up to homotopy (making use of the fact that the quasi-inverse to $H^*(F)$ may be chosen freely). Note that $H^*(G)$ is a functor as $m - 1 \geq 2$.

Since $H^*(\phi)$ also being a functor (as $n - m \geq 3$) preserves invertible maps, we conclude by Lemma 5.9 that it preserves homotopies. Hence $\phi(G)$ is an inverse to $\phi(F)$ up to homotopy. It follows that $H^*(\phi(F))$ is an equivalence $H^*(a \coprod b) \rightarrow H^*(a' \coprod b')$.

For the next few results we assume that $a, b$ are $A_q$ categories and that $M$ is an $A_q$-$b$-$a$-bimodule. We define $M^{s+2}$ as the $b$-$b$-$a$-$a$ bimodule such that $M^{s+2}((A_0 \oplus A_1, \delta_0), (B_0 \oplus B_1, \delta_1)) = M(A_0, B_0) \oplus M(A_0, B_1) \oplus M(A_1, B_0) \oplus M(A_1, B_1)$ where the higher operations on $M^{s+2}$ are obtained from those of $M$ by “inserting Maurer-Cartan elements” like in Lemma 6.3. In a similar way as Lemma 6.4 one proves

Lemma 9.8. $M^{s+2}$ is a $A_{(n-1)/2}^{s+2}$-bimodule.

Lemma 9.9. Let $n \geq 3$ and let $a, b, M$ be as above. We have a fully faithful functor of $A_{(n-1)/2}^{s+2}$ categories

\[(a \coprod M b) \ast (a \coprod M b) \rightarrow a \ast a \coprod M^{s+2} b \ast b\]

Proof. An object in $(a \coprod M b) \ast (a \coprod M b)$ is of the form

\[(A_0 \oplus B_0, \delta_0) \oplus (A_1 \oplus B_1, \delta_1), \delta\]

where $\delta = (\delta_{00}, \delta_{01}, \delta_{11}) \in a(A_0, A_1) \oplus M(A_0, B_1) \oplus b(B_0, B_1)$ is such that

\[\delta = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \delta_{00} & 0 & 0 & 0 \\ \delta_{01} & \delta_{11} & 0 & 0 \end{pmatrix} \text{ acting on } \begin{pmatrix} A_0 \\ B_0 \\ A_1 \\ B_1 \end{pmatrix}\]

is a Maurer-Cartan element in $(a \coprod M b)^{\oplus 2}$. One verifies that the following matrix

\[\Delta = \begin{pmatrix} 0 & 0 & 0 & 0 \\ \delta_{00} & 0 & 0 & 0 \\ \delta_{01} & \delta_{11} & 0 & 0 \end{pmatrix} \text{ acting on } \begin{pmatrix} A_0 \\ B_0 \\ A_1 \\ B_1 \end{pmatrix}\]

defines a Maurer-Cartan element in $(a \coprod M b)^{\oplus 4}$. Rearranging $\Delta$ we get a different Maurer-Cartan element in $(a \coprod M b)^{\oplus 4}$

\[\Delta^* = \begin{pmatrix} 0 & 0 & 0 & 0 \\ \delta_{00} & 0 & 0 & 0 \\ \delta_{01} & \delta_{11} & 0 & 0 \end{pmatrix} \text{ acting on } \begin{pmatrix} A_0 \\ B_0 \\ A_1 \\ B_1 \end{pmatrix}\]

which is a block-matrix representation for an object in $(a \ast a) \coprod M^{s+2} (b \ast b)$. This construction defines and injection $\text{Ob}((a \coprod M b) \ast (a \coprod M b)) \hookrightarrow \text{Ob}(a \ast a \coprod M^{s+2} b \ast b)$ (but not a bijection) which is compatible
with Hom-sets. It is now an easy verification (but messy to write down) that we also get compatibility with higher operations.

The bimodule $M$ may be extended to a $\text{Free}(b)$-$\text{Free}(a)$-$A_n$-bimodule which we denote by $\text{Free}(M)$.

**Lemma 9.10.** We have a fully faithful functor of $A_{n-1}$-categories

$$\text{Free}(a \coprod_M b) \to \text{Free}(a) \coprod_{\text{Free}(M)} \text{Free}(b).$$

**Proof.** An object in $\text{Free}(a \coprod_M b)$ is of the form $\bigoplus_{i \in I} \Sigma^n_i (A_i \oplus B_i, \delta_i)$. We send it to $(\bigoplus_i \Sigma^n_i A_i \oplus \bigoplus_i B_i, \bigoplus_i \delta_i)$. It is easy to see that this operation is fully faithful.

Now we put $\mathcal{T}_B \leq 1 M = (\text{Free} M)^{\leq 2}$. From Lemma 9.8 we obtain

**Lemma 9.11.** $\mathcal{T}_B \leq 1 M$ is a $A_{(n-1)/2}$-bimodule.

**Corollary 9.12.** Assume $n \geq 3$. There is a fully faithful functor of $A_{[(n-1)/2]-1}$-categories

$$\mathcal{T}_B \leq 1 (a \coprod_M b) \to \mathcal{T}_B \leq 1 a \coprod_{\mathcal{T}_B \leq 1 M} \mathcal{T}_B \leq 1 b$$

whose restriction to $a \coprod_M b$ is of the form $(\Phi, I, \Phi^*)$ where $\Phi : a \to \mathcal{T}_B \leq 1 a$ is as in Definition 6.5, $\Phi^* : b \to \mathcal{T}_B \leq 1 b$ is the related map $B \mapsto (0 \oplus B, 0)$ and $I : M \to \mathcal{T}_B \leq 1 M_{\Phi}$ is the obvious inclusion.

**Proof.** The existence of (9.4) follows by combining Lemma 9.9 and 9.10. The fact that the restriction to $a \coprod_M b$ has the indicated form follows from the construction of the map.

**Proof of Theorem 9.5.** If $n \geq 3$ then $\mathcal{T}_B \leq 1 a, \mathcal{T}_B \leq 1 b$ are at least $A_6$-categories by Lemma 6.6, and by Lemma 9.11 $\mathcal{T}_B \leq 1 M$ is at least an $A_6$-bimodule. We can use Corollary 9.7 with $n = 6$ and $m = 3$, together with Lemma 9.13 below to conclude that the composition

$$a \coprod_M b \to \mathcal{T}_B \leq 1 (a \coprod_M b) \to \mathcal{T}_B \leq 1 a \coprod_{\mathcal{T}_B \leq 1 M} \mathcal{T}_B \leq 1 b$$

(which is equal to $(\Phi, I, \Phi^*)$ by Corollary 9.12) is a quasi-equivalence. Since both functors are fully faithful (the second one by Corollary 9.12), the first one must be a quasi-equivalence as well.

Put $c = a \coprod_M b$. The claim about the exactness of $\varphi_a, \varphi_b$ follows from Theorem 6.11. We clearly also have $H^*(c)(H^*(b), H^*(a)) = 0$. So to show that we have a semi-orthogonal decomposition as in (9.2) we have show that every object $C$ in $H^*(c)$ is of the form $C \cong \text{cone}(C_a \to C_b)$ with $C_a \in \text{Ob}(a), C_b \in \text{Ob}(b)$. Assume $C = (A \oplus B, \delta)$. We have a fully faithful functor $a \coprod_M b \subset \text{Free} a \coprod_{\text{Free} M} \text{Free} b$ and the latter category is also pre-triangulated (as “Free” preserves $A$-ness). Again by Theorem 6.11 this functor is exact. The following triangle

$$\Sigma^{-1} A \xrightarrow{\alpha \delta} B \xrightarrow{i} C \xrightarrow{p} \Sigma^{-1} A$$

is distinguished in $H^*(\text{Free} a \coprod_{\text{Free} M} \text{Free} b)$ as it is trivially isomorphic to the standard triangle $\delta_{\alpha \delta}$ in $H^*(\mathcal{T}_B \leq 1 (\text{Free} a \coprod_{\text{Free} M} \text{Free} b))$. Choose $A' \in \text{Ob}(a)$ such that $A' \cong \Sigma^{-1} A$ in $\text{Free} a$ ($A'$ is a desuspension of $A$). Then by the axioms of triangulated categories we obtain $\text{cone}(A' \to B) \cong C$ in $H^*(\text{Free} a \coprod_{\text{Free} M} \text{Free} b)$. By fully faithfulness this isomorphism also holds in $H^*(a \coprod_M b)$. The fact that the corresponding bimodule is as given is clear.

**Lemma 9.13.** Let $a$ be an $A_n$-category. The strict $A_{(n-1)/2}$-functors $\Phi, \Phi^* : a \to \mathcal{T}_B \leq 1 a$ given by $\Phi(A) = (A \oplus 0, 0), \Phi^*(A) = (0 \oplus A, 0)$ are homotopic.

**Proof.** The homotopy $h$ is such that $h_n = 0$ for $n \geq 1$ and $h_0$ is the matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.
### 10. Higher Toda Brackets in Triangulated and $A_{\infty}$-Categories

#### 10.1. Postnikov systems.

Let

\[ X^* : X_0 \rightarrow X_1 \rightarrow \cdots \rightarrow X_n \]

be a complex in a triangulated category $\mathcal{T}$, i.e., a sequence of composable morphisms in $\mathcal{T}$ such that the composition of any two consecutive morphisms is zero. A **Postnikov system** for $X^*$ is any exact diagram in $\mathcal{T}$ of the form

\[ \begin{array}{ccc}
Y_0 & \xrightarrow{(1)} & Y_1 \\
\cup & \pi & \cup \\
X_0 & \xrightarrow{d} & X_1 \end{array} \]

where the triangles marked with $\cup$ are commutative and the triangles marked with $\pi$ are distinguished. This means that we should have the following distinguished triangles

\[ Y_i \rightarrow X_{i+1} \rightarrow Y_{i+1} \xrightarrow{(1)} Y_i \]

with $X_0 = Y_0$. A Postnikov system need not exist and if it exists it may not be unique. If a Postnikov system exists then the object $Y_n$ will be called a **convolution** of $X^*$.

**Remark 10.1.** Sometimes it is helpful to think of a convolution $Y_n$ as an object with an ascending filtration with subquotients (starting from the bottom) $X_n, \Sigma X_{n-1}, \Sigma^2 X_{n-2}, \ldots, \Sigma^n X_0$. In particular the convolution $Y_n$ comes with maps

\[ Y_n \xrightarrow{p} X_0 \xrightarrow{(n)} X_n \]

where $i$ is as (10.2) and $p$ is the composition $Y_n \rightarrow Y_{n-1} \rightarrow \cdots \rightarrow Y_0 = X_0$ in that same diagram. Note that $pi = 0$.

#### 10.2. Existence.

Some existence and functoriality results for Postnikov systems are stated in [10, Lemmas 1.5, 1.6] but since they require the vanishing of arbitrary negatives $\Ext^i$s between suitable objects, they are not completely sufficient for our purposes. So we give some slightly strengthened versions in the next two sections.

**Lemma 10.2.** Assume $X^*$ is a complex in a triangulated category $\mathcal{T}$ such that

\[ \mathcal{T}(X_a, X_b)^{- (b-a) + 2} = 0 \quad \text{for} \quad b \geq a + 3. \]

Then $X^*$ may be extended to a Postnikov system. Moreover if the following condition holds

\[ \mathcal{T}(X_a, X_b)^{- (b-a) + 1} = 0 \quad \text{for} \quad b \geq a + 2 \]

then such an extension is unique, up to non-unique isomorphism.
Proof. The Posnikov system built on $X^*$ will be constructed inductively. Assume we have constructed the part involving $X_0, X_1, \ldots, X_i, Y_0, Y_1, \ldots, Y_i$ (so this is a Posnikov system on $X_0 \to \cdots \to X_i$). To lift the map $X_i \to X_{i+1}$ to a map $Y_i \to X_{i+1}$ we need that the composition

$$Y_{i-1} \to X_i \to X_{i+1}$$

is zero. Since the composition of $X_{i-1} \to X_i \to X_{i+1}$ is zero by definition it follows from (10.3) that we should have $T(Y_{i-2}, X_{i+1})\sim 0$. Using Remark 10.1 we see that this condition is implied by (10.5).

Once we have lifted to $X_i \to X_{i+1}$ to $Y_i \to X_{i+1}$ we may construct $Y_{i+1}$ via the distinguished triangle (10.3).

To obtain uniqueness we note that if $X^*$ can be extended to two Posnikov systems then by Lemma 10.3 below the identity on $X^*$ can be extended to a morphism between these Postnikov systems. It is then easy to see that this extension must be an isomorphism.

10.3. Weak functoriality.

Lemma 10.3. Assume we have a morphism of complexes in a triangulated category $T$

$$X_0 \to X_1 \to X_2 \to \cdots \to X_n$$

such that the following conditions hold

$$T(X_a, X'_b)\sim 0 \quad \text{for } b \geq a + 2$$

Then (10.7) can be extended to a map of Postnikov systems (not necessarily uniquely).

Proof. We work inductively. Assume that we have defined the extended map on $Y_0, \ldots, Y_i$ with the required commutativity holding on $Y_0, \ldots, Y_i, X_0, \ldots, X_i$. We perform the induction step. We have a diagram

$$Y_i \to X_{i+1} \to Y_{i+1} \to Y_i$$

We do not know that the leftmost square is commutative, so let the dotted arrow denote the difference of the two compositions. From the following diagram

$$X_i \to Y_i \to X_{i+1}$$

$$X'_i \to Y'_i \to X'_{i+1}$$

we obtain that the composition of $\delta$ with $X_i \to Y_i$ is zero. So in view of the distinguished triangle

$$Y_{i-1} \to X_i \to Y_i \to Y_{i-1}$$

$\delta$ will be zero provided $T(Y_{i-1}, X'_{i+1})\sim 0$. This follows from Remark 10.1 and the hypothesis (10.8).

So $\delta = 0$ and the square in (10.9) is commutative. We now finish by invoking TR3.
10.4. **Higher Toda brackets.** In this section we define higher Toda brackets. One may verify that they are the same as those defined in [5].

**Definition 10.4.** Let $X^* = (((X_i)_{i=0}^n (d_i)_{i=0}^{n-1})$ for $n \geq 3$ be a complex in a triangulated category $\mathcal{T}$. The (higher) Toda bracket $\langle X^* \rangle \subset \mathcal{T}(X_0, X_{n}−n+2)$ of $X^*$ is the collection of compositions $\beta \alpha$ where $\alpha, \beta$ fit in the following commutative diagram

\[
\begin{array}{ccc}
X_0 & \xrightarrow{d_0} & X_1 \\
& \searrow & \nearrow \\
& p & \circlearrowright \\
& \downarrow & \nwarrow \\
& (n-2) & \downarrow \beta \\
& \uparrow a & \nearrow \\
X_{n-1} & \xrightarrow{\cdot} & Y \\
& \downarrow \circlearrowright \\
X_n & \xrightarrow{\cdot d_{n-1}} & X_n
\end{array}
\]

where $Y$ is a convolution of $(X_i)_{i=1}^{n-1}$ and $p, i$ are as in (10.4).

Note that if $n > 3$ then $\langle X^* \rangle$ may be empty.

**Theorem 10.5.** Let $X^*$ be as in Definition 10.4.

1. If $t \in \langle X^* \rangle$ then $t + d_{n-1} \mathcal{T}(X_0, X_{n-1})_{n-2} + \mathcal{T}(X_1, X_n)_{n+2}d_0 \subset \langle X^* \rangle$.
2. If

\[
\mathcal{T}(X_a, X_b)_{-(b-a)+2} = 0 \quad \text{for } b - a \in [3, n-1].
\]

then $\langle X^* \rangle \neq \emptyset$.

3. If moreover

\[
\mathcal{T}(X_a, X_b)_{-(b-a)+1} = 0 \quad \text{for } b - a \in [2, n-2]
\]

then $\langle X^* \rangle$ is a coset of $d_{n-1} \mathcal{T}(X_0, X_{n-1})_{n-2} + \mathcal{T}(X_1, X_n)_{n+2}d_0$.

**Proof.** (1) If $\phi \in \mathcal{T}(X_0, X_{n-1})_{n+2}$ then as $\beta \phi = 0$, adding to $i \phi$ to $\alpha$ still keeps the diagram (10.10) commutative. Since $\beta i \phi = d_{n-1} \phi$ we obtain that $t + d_{n-1} \phi \in \langle X^* \rangle$. A similar reasoning applies if we start with $\phi \in \mathcal{T}(X_1, X_n)_{n+2}$.

(2) Note that (10.11) implies in particular (10.5) for $(X_i)_{i=1}^{n-1}$. So a convolution $Y$ as in (10.10) exists and we have to verify the existence of $\alpha$ and $\beta$. We will now introduce notations similar to §10.1. So we will denote the Postnikov systems giving rise to $Y$ by $Y_1, \ldots, Y_{n-1}$ where $Y_{n-1} = Y$ and $Y_1 = X_1$.

We first consider the existence of $\beta$. We have a distinguished triangle

\[
Y_{n-2} \rightarrow X_{n-1} \xrightarrow{f} Y_{n-1} \rightarrow
\]

Thus in order for the map $d_{n-1} : X_{n-1} \rightarrow X_n$ to factor through $Y_{n-1}$ we have to prove that the composition $Y_{n-2} \rightarrow Y_{n-1} \rightarrow X_n$ is zero. Since we already know that the composition $X_{n-2} \rightarrow Y_{n-2} \rightarrow X_{n-1} \rightarrow X_n$ is zero and there is a distinguished triangle

$X_{n-2} \rightarrow Y_{n-2} \rightarrow \Sigma Y_{n-3} \rightarrow$

it is sufficient to show that $\mathcal{T}(\Sigma Y_{n-3}, X_n) = 0$. Now by Remark 10.1, $\Sigma Y_{n-3}$ has subquotients $\Sigma X_{n-3}, \ldots, \Sigma^{n-2} X_1$. The conclusion now follows from (10.11).

Now we look at the existence of $\alpha$. We will successively lift $X_0 \xrightarrow{d_0} X_1 = Y_1$ to maps $X_0 \xrightarrow{(−1)} Y_2, \ldots, X_0 \xrightarrow{(−n+2)} Y_{n-1}$. The last map is the sought $\alpha$. First we look at the distinguished triangle

$X_1 \rightarrow X_2 \rightarrow Y_2 \rightarrow$
Since the composition $X_0 \rightarrow X_1 \rightarrow X_2$ is zero the map $d_0$ factors through $\Sigma^{-1}Y_2$. To continue we use the distinguished triangles

$$Y_{i-1} \rightarrow X_{i} \rightarrow Y_i \rightarrow$$

for $3 \leq i \leq n - 1$. Assume we have constructed the map $X_0 \rightarrow \Sigma^{-i+2}Y_{i-1}$. From (10.11) we obtain that the composition $X_0 \rightarrow \Sigma^{-i+2}Y_{i-1} \rightarrow \Sigma^{-i+2}X_i$ is zero and hence $X_0 \rightarrow \Sigma^{-i+2}Y_{i-1}$ factors through $\Sigma^{-i+1}Y_i$ and we can continue.

(3) First we observe that (10.12) implies in particular (10.6) and hence the Postnikov system built on $(X_i)_{i=1}^{n-1}$ is unique. To prove asserted statement we have to investigate the freedom in choosing $\alpha$ and $\beta$.

Again we will discuss $\beta$ first. $\beta$ is determined up to an element of the kernel of $T(Y_{n-1}, X_n) \rightarrow T(X_{n-1}, X_n)$. Using the distinguished triangle (10.13) we see that $\beta$ is determined up to a composition of the form $Y_{n-1} \rightarrow \Sigma Y_{n-2} \rightarrow X_n$. Using Remark 10.1 we see that $\Sigma Y_{n-2}$ has subquotients $\Sigma X_{n-2}, \Sigma^2 X_{n-3}, \ldots, \Sigma^{n-2} X_1$. Hence by (10.12) any morphism $\Sigma Y_{n-2} \rightarrow X_n$ factors through $\Sigma^{n-2}X_1$. It follows that $\beta$ is determined up to a composition of the form $Y_{n-1} \rightarrow (\Sigma Y_{n-2} \rightarrow X_n)$.

Composing with $\alpha$ we see as in (1) that changing $\beta$ in this way, changes $\beta\alpha$ by an element of $T(X_1, X_n)_{n+2}d_0$.

Now we discuss $\alpha$. $\alpha$ is determined up to an element of $\ker(T(X_0, Y_{n-1})_{n+2} \rightarrow T(X_0, X_1))$. Define $Y'_{i} = \Sigma^{-1}\text{cone}(Y_i \rightarrow \Sigma^{-1}X_1)$, so that in particular $Y'_{1} = 0, Y'_{2} = X_2$. Using the octahedral axiom we may construct commutative diagrams for $i = 2, \ldots, n - 1$

$$\begin{array}{ccc}
\Sigma Y'_{i-1} & \rightarrow & \Sigma Y_{i-1} \\
\downarrow & & \downarrow \\
\Sigma^{-1}X_1 & \rightarrow & \Sigma^{-1}X_1 \\
\downarrow & & \downarrow \\
Y'_{i} & \rightarrow & Y_i \\
\downarrow & & \downarrow \\
X'_{i} & \rightarrow & X_i \\
\end{array}$$

with rows and columns that are distinguished triangles, where the maps not involving $Y'$'s are taken from the Postnikov system. Hence similar to Remark 10.1, $Y'_{i}$ has subquotients $X_i, \Sigma X_{i-1}, \ldots, \Sigma^{n-2}X_2$.

We have a distinguished triangle

$$Y'_{n-1} \rightarrow Y_{n-1} \rightarrow \Sigma^{-n}X_1 \rightarrow$$

and hence $\alpha$ is determined up to a composition $X_0 \rightarrow \Sigma^{-n+2}Y'_{n-1} \rightarrow \Sigma^{-n}Y_{n-1}$. Now $\Sigma^{-n+2}Y'_{n-1}$ has subquotients $\Sigma^{-n+2}X_{n-1}, \ldots, \Sigma^{-1}X_1$ and hence by (10.12) we obtain that any map $X_0 \rightarrow \Sigma^{-n+2}Y'_{n-1}$ factors through $\Sigma^{-n+2}X_{n-1}$. Hence we obtain that $\alpha$ is determined up to a composition $X_0 \rightarrow \Sigma^{-n+2}X_{n-1} \rightarrow \Sigma^{-n+2}Y'_{n-1}$ which by construction is the same as a composition $X_0 \rightarrow \Sigma^{-n+2}X_{n-1} \rightarrow \Sigma^{-n+2}Y_{n-1}$ which by construction is the same as $X_0 \rightarrow \Sigma^{-n+2}Y_{n-1}$. We now finish as for $\beta$. \qed
10.5. **Postnikov systems associated to twisted complexes.** In this section \(a\) is an \(A_{\infty}\)-category.

10.5.1. **More on the category \(\text{Free}(a)\).** Recall that in §5.6 we introduced the strict endo-functor \(\Sigma\) of \(\text{Free}(a)\). Below we introduce some more notation concerning the category \(\text{Free}(a)\). If \(X = \Sigma^c Y\) for \(Y \in \text{Ob}(a)\) then we let \(\eta_{X,a,b} : \Sigma^a X \to \Sigma^b X\) be given by \(\sigma^{b-a} \text{id}_Y\). Note that \(m_2(\eta_{X,a,b}, \eta_{X,a,b}) = \eta_{X,a,c}\). All operations on \(a\), except \(m_2\), vanish when one of its arguments is of the form \(\eta_{X,a,c}\). Moreover we have formulas

\[
m_n(\ldots, f, m_2(\eta_{X,a,b}, g), \ldots) = m_n(\ldots, m_2(f, \eta_{X,a,b}), g, \ldots)
\]

\[
m_n(m_2(\eta_{X,a,b}, f), \ldots) = (-1)^{(c-2+n)(b-a)} m_2(\eta_{X,a,b}, m_n(f, \ldots))
\]

\[
m_n(\ldots, m_2(g, \eta_{X,a,b}))) = m_2(m_n(\ldots, g), \eta_{X,a,b}).
\]

and their \(b\)-versions which are useful for computations

\[
b_n(\ldots, s f, sm_2(\eta_{X,a,b}, g), \ldots) = (-1)^{b-a} b_n(\ldots, sm_2(f, \eta_{X,a,b}), sg, \ldots)
\]

\[
b_n(sm_2(\eta_{X,a,b}, f), \ldots) = m_2(\eta_{X,a,b}, b_n(s f, \ldots))
\]

\[
b_n(\ldots, sm_2(g, \eta_{X,a,b}))) = m_2(b_n(\ldots, sg), \eta_{X,a,b}).
\]

Below we usually write \(\eta_{X,a,b} g\) for \(m_2(\eta_{X,a,b}, g)\) and similarly \(m_3(g, \eta_{X,a,b})\). By the vanishing of \(m_3\) on arguments involving \(\eta_{X,a,b}\) this will not lead to confusion. Sometimes we also write \(\eta_{X,a,b}^{-1}\) for \(\eta_{X,b,a}\). One verifies using the definition of the functor \(\Sigma\) (see §5.6) that for \(f : \Sigma^a X \to \Sigma^b Z\) one has

\[
\Sigma^a f = (-1)^{a/1} f \eta_{Z,b,a+n, a}.
\]

Finally we put \(\eta_X = \eta_{X,0,1}\).

10.5.2. **More on the triangulated structure of \(\text{Tw} a\).** Let \(f : (A, \delta_A) \to (B, \delta_B)\) be a closed morphism of degree 0 in \(\text{Tw} a\). To \(f\) we associate a triangle in \(H^4(\text{Tw} a)\).

\[
(A, \delta_A) \xrightarrow{f} (B, \delta_B) \xrightarrow{i} (C(f), \delta_{C(f)}) \xrightarrow{p} (A, \delta_A)
\]

where \(C(f) = \Sigma A \oplus B\) and

\[
\delta_{C(f)} = \begin{pmatrix}
\Sigma \delta_A & 0 \\
\eta_A^{-1} & \delta_B
\end{pmatrix}
\]

and furthermore

\[
i = \begin{pmatrix} 0 \\ \text{id}_B \end{pmatrix}, \quad p = (\eta_A^{-1} 0).
\]

The following lemma is an easy verification:

**Lemma 10.6.** The triangles (10.16) are distinguished according to Definition 6.10.

10.5.3. **Postnikov systems from objects in \(\text{Tw} a\).**

**Proposition 10.7.** A twisted complex in \(\text{Tw} a\)

\[
Y_n = (\Sigma^n X_0 \oplus \Sigma^{n-1} X_1 \oplus \ldots \oplus X_n, \delta)
\]

with \(X_i \in \text{Free}(a)\) gives rise to a Postnikov system in \(H^4(\text{Tw} a)\) built on the complex

\[
X_0 \xrightarrow{d_0} X_1 \xrightarrow{d_1} \ldots \xrightarrow{d_{n-1}} X_n
\]

with

\[
d_{j-1} = (-1)^{n-j} \eta_{X_j,n-j,0} \cdot \delta_{j,j-1} \cdot \eta_{X_{j-1},0,n-j+1},
\]
where $\delta_{k,j-1} : \Sigma^{n-1} X_{j-1} \to \Sigma^{n-1} X_j$ is the $(j, j-1)$ entry of the matrix $\delta$ (the ~'s are for easier reading).

In the Postnikov system we also have

$$Y_j = (\Sigma^j X_0 \oplus \Sigma^{j-1} X_1 \oplus \cdots \oplus X_j, \delta_Y)$$

such that $\Sigma^{n-1} \delta_Y$ is given by the upper left $j + 1 \times j + 1$-square in the matrix representing $\delta$.

Finally the maps $p : Y_n \to X_0$, $i : X_n \to Y_n$ as in (10.4) are given by

$$i = \begin{pmatrix} 0 \\ \vdots \\ \text{id}_{X_n} \end{pmatrix}, \quad p = (\eta_{X_{n-1}}, 0, \ldots, 0)$$

**Proof.** We may write

$$\delta_Y = \begin{pmatrix} \Sigma \delta_{j-1} \\ f_j \eta_{j-1} \\ 0 \end{pmatrix}$$

where $f_j : (Y_{j-1}, \delta_{j-1}) \to X_j$ is the closed map in $\text{Tw} \alpha$ with matrix

$$((\delta_Y)_{j,0} \eta_{j-1} X_0, \ldots, (\delta_Y)_{j,j-1} \eta_{X_{j-1}}).$$

Clearly $Y_j = C(f_j)$ so that we have standard triangles

$$(10.19) \quad Y_{j-1} \xrightarrow{f_j} X_j \xrightarrow{i_j} Y_j \xrightarrow{p_j} Y_{j-1}$$

where $(i_j, p_j)$ are as in (10.17). In particular $i = i_n$ is given by the formula (10.18). We compute the composition

$$X_{j-1} \xrightarrow{i_{j-1}} Y_{j-1} \xrightarrow{f_j} X_j$$

It is given by the matrix multiplications

$$((\delta_{Y_j})_{j,0} \eta_{j-1} X_0, \ldots, (\delta_{Y_j})_{j,j-1} \eta_{X_{j-1}}) \begin{pmatrix} 0 \\ \vdots \\ \text{id}_{X_{j-1}} \end{pmatrix} = (\delta_{Y_j})_{j,j-1} \eta_{X_{j-1}}$$

which is equal to $(\Sigma^{-(n-j)}(\delta_{Y_n})_{j,j-1}) \eta_{X_{j-1}}$. One computes using (10.15) that the latter expression is equal to $d_{j-1}$.

Finally to show $p$ is as in (10.18) we use $p = p_1 \cdots p_{n-1} p_n$ by the description in Remark 10.1. Then we use the formula (10.17) for $p_j$. \hfill $\square$

10.6. **Higher Toda brackets in $A_\infty$-categories.** We prove the following result.

**Theorem 10.8.** Let $a$ be a pre-triangulated $A_\infty$-category and let $X_0 \xrightarrow{d_0} X_1 \xrightarrow{d_1} \cdots \xrightarrow{d_{n-1}} X_n$ be a complex in $\mathcal{T} = H^*(a)$. Assume the following conditions hold:

1. The $A_\infty$-subcategory of $a$ spanned by the objects $(X_i)_a$ is minimal (i.e. $b_1 = 0$).
2. $a(X_i, X_j)_a = 0$ for $-n + 2 < u < 0$.

Using (1) we may regard $d_i$ as closed arrows in $a$. With this convention we have that $(X^*)$ is the coset for $d_{n-1} \mathcal{T} (X_0, X_{n-1})_{n+2} + \mathcal{T} (X_1, X_n)_{n+2} d_0$ given by $s^{-1} b_0 (s d_{n-1}, \ldots, s d_0)$. 
Proof. Since (10.11) and (10.12) hold it is sufficient to produce a single element of \( \langle X' \rangle \). Since higher Toda brackets are obviously invariant under equivalences of triangulated categories we may perform the calculation in \( Tw \mathfrak{a} \). We start with the Postnikov system built on \( X_1 \xrightarrow{d_1} X_2 \xrightarrow{d_2} \cdots \xrightarrow{d_{n-2}} X_{n-1} \). By Proposition 10.7 it is obtained from the twisted complex
\[
Y = (\Sigma^{n-2} X_1 \oplus \cdots \oplus X_{n-1}, \delta)
\]
where the only non-zero entries of \( \delta \) are \( \delta_{j,j-1} \) for \( j = 2, \ldots, n-1 \) and \( \delta_{j,j-1} \) is given by
\[
\delta_{j,j-1} = (-1)^{n-1-j} \eta_{X_j,0,n-1-j} \cdot d_{j-1} \cdot \eta_{X_{j-1},n-j,0}
\]
Using the formulas for \( i \) and \( p \) (see (10.18)) it is then easy to see that we may take
\[
\alpha = \begin{pmatrix}
\eta_{X,0,n-2d_0}
\vdots
0
\end{pmatrix}
\]
and
\[
\beta = (0, 0, \ldots, d_{n-1})
\]
Then
\[m_{Tw \mathfrak{a}, 2}(\beta, \alpha) \in \langle X' \rangle.
\]
It will be more convenient to compute \( b_{Tw \mathfrak{a}, 2}(s \beta, sa) = sm_{Tw \mathfrak{a}, 2}(\beta, \alpha)\). We have
\[
b_{Tw \mathfrak{a}, 2}(s \beta, sa) = b_{\mathfrak{a}, a}(s \beta, s \delta, \ldots, s \delta, sa)
\]
\[
= b_{\mathfrak{a}, a}(sd_{n-1}, sd_{n-2} \cdot \eta_{X_{n-2},1,0}, \ldots, \ldots, (-1)^{n-1-j} \cdot s \eta_{X_j,0,n-1-j} \cdot d_{j-1} \cdot \eta_{X_{j-1},n-j,0}, \ldots, \ldots)
\]
\[
= b_{\mathfrak{a}, a}(sd_{n-1}, sd_{n-2}, \ldots, d_{n-1}, d_{n-2}, \ldots, d_0)
\]
where in the last line we have used (10.14).

11. TRIANGULATED CATEGORIES WITHOUT MODELS

If \( \mathfrak{A} \) is a triangulated category then an \( A_\infty \)-enhancement on \( \mathfrak{A} \) is a pair consisting of a pre-triangulated \( A_\infty \)-category \( \mathfrak{a} \) such that \( \text{Ob}(\mathfrak{a}) = \text{Ob}(\mathfrak{A}) \) and an isomorphism of triangulated categories \( H^*(\mathfrak{a}) \to \mathfrak{A} \) inducing the identity on objects. The following proposition will be the basis for constructing a triangulated category that does not admit an \( A_\infty \)-enhancement.

Proposition 11.1. Let \( \mathfrak{a}, \mathfrak{b} \) be pre-triangulated \( A_\infty \)-categories. Suppose we have an \( A_\infty \)-functor \( F : \mathfrak{a} \to \mathfrak{b} \) for \( n \geq 13 \) such that \( H^*(F) \) does not lift to an \( A_\infty \)-functor for any \( A_\infty \)-enhancements on \( H^*(\mathfrak{a}) \) and \( H^*(\mathfrak{b}) \). Let \( \mathfrak{c} \) be the gluing category \( \mathfrak{c} = \mathfrak{a} \coprod M \mathfrak{b} \) where \( M = K \mathfrak{b} \) (see §9.1). Then \( H^*(\mathfrak{c}) \) is a triangulated category which does not admit an \( A_\infty \)-enhancement.

Proof. By the discussion in §9.1, \( M \) is an \( A_{13} \)-bimodule. Therefore by Theorem 9.5, \( \mathfrak{c} \) is a pre-triangulated \( A_{13} \)-category. Hence by Theorem 8.3, \( H^*(\mathfrak{c}) \) is triangulated.

Suppose that an \( A_\infty \)-enhancement \( \mathfrak{b} \) on \( H^*(\mathfrak{c}) \) exists. Since \( H^*(\mathfrak{a}), H^*(\mathfrak{b}) \) are full exact subcategories of \( H^*(\mathfrak{c}) \), it follows that the \( A_\infty \)-structure on \( \mathfrak{b} \) induces \( A_\infty \)-enhancements \( \mathfrak{a}', \mathfrak{b}' \) on \( H^*(\mathfrak{a}) \) and \( H^*(\mathfrak{b}) \). By \( H^*(\mathfrak{b}) \cong H^*(\mathfrak{c}) \) it follows that \( \mathfrak{b}(A, B)_{\mathfrak{A}, \mathfrak{B}} \) for \( A \in \text{Ob}(H^*(\mathfrak{a})), B \in \text{Ob}(H^*(\mathfrak{b})) \) defines a \( A_\infty \)-\( \mathfrak{b}' \)-\( \mathfrak{a}' \)-bimodule which is a co-quasi-functor in the sense of §11.1 below. Hence by Lemma 11.4, \( \mathfrak{b} \) induces an \( A_\infty \)-functor \( F' : \mathfrak{a}' \to \mathfrak{b}' \) such that \( H^*(F') \cong F \). This contradicts the hypotheses on \( F \).
Remark 11.2. The idea of creating a triangulated category without model by gluing a non-enhanceable functor was suggested to us by Bondal and Orlov on a number of occasions. In fact, the idea of translating an enhancement of the glued category into a $A_{\infty}$-enhancement of the gluing functor, thereby obtaining a contradiction, was specifically suggested to us by Orlov.

11.1. Co-quasi-functors. To fill in a missing ingredient in the proof of Proposition 11.1 we use an $A_{\infty}$ version of the notion of a (co)-quasi-functor (see [6]). In the rest of this section we assume that $a$, $b$ are $A_{\infty}$-categories.

Definition 11.3. An $A_{\infty}$-$b$-$a$-bimodule $M$ is a co-quasi-functor $a \rightarrow b$ if for every object $A \in \text{Ob}(a)$ there exists $f A \in \text{Ob}(b)$ together with an element $\tilde{\phi}_A \in (H^* M)(A, f A)_0$ inducing an isomorphism for all $B \in \text{Ob}(b)$: $\tilde{\phi}_A : H^*(f A, B) \rightarrow (H^* M)(A, B) : u \mapsto u\tilde{\phi}_A$.

It is clear from the definition that being a co-quasi-functor depends only on the structure of $H^* M$ as graded $H^*(a) - H^*(b)$-bimodule. A co-quasi-functor induces an actual functor $f^o : H^*(a) \rightarrow H^*(b)$. Indeed for $u : A \rightarrow A'$ in $H^*(a)$, $f^o u : f A \rightarrow f A'$ is defined to be the unique morphism such that $H^*(b)(f^o u, -)$ is the composition $H^*(b)(f A', -) \xrightarrow{\phi_{M(f,-)}\tilde{\phi}_A^{-1}} (H^* M)(A', -) \xrightarrow{\tilde{\phi}_A} H^*(b)(f A, -)$. Moreover it is clear that different choices of $(\phi_A, f^o A)$ lead to naturally isomorphic functors.

Lemma 11.4. Assume that $M$ is a co-quasi-functor $a \rightarrow b$ and let $f^o : H^*(a) \rightarrow H^*(b)$ be the induced functor as explained above. Then there exists an $A_{\infty}$-functor $f : a \rightarrow b$ such that $H^*(f) = f^o$.

Proof. Let $C_{\infty}^l(b)$ be the DG-category of strictly unital left $A_{\infty}$-$b$-modules [7, Chapitre 5] and let $Y : b \rightarrow C_{\infty}^l(b)^o : B \mapsto b(B, -)$ be the Yoneda embedding. Furthermore let $\tilde{b} \subset C_{\infty}^l(b)^o$ be the full subcategory spanned by $A_{\infty}$-modules $M$ which are $A_{\infty}$-quasi-isomorphic to some $b$-module of the form $b(B, -)$. Clearly we have that $Y$ corestricts to an $A_{\infty}$-quasi-equivalence $Y^c : b \rightarrow \tilde{b}$. Since $M$ is a co-quasi-functor the image of the $A_{\infty}$-functor $F : a \rightarrow C_{\infty}^l(b)^o : A \mapsto M(A, -)$ lies in $\tilde{b}$. Let $F^c : a \rightarrow \tilde{b}$ be the corestriction of $F$.

Choose an $A_{\infty}$-quasi-inverse $W : \tilde{b} \rightarrow b$ to the quasi-equivalence $Y^c : b \rightarrow \tilde{b}$ which sends $M(A, -)$ to $f A$ for $A \in \text{Ob} a$ and $u$ to (a representative of) $f^o u$ for $u : A \rightarrow A'$ a closed map in $a$. By Lemma 5.10 this is possible. Then one easily verifies that $f^c = H^*(F^c W)$.

Remark 11.5. It is also easy to prove that we have an quasi-isomorphism of $A_{\infty}$-bimodules $f \tilde{b} \equiv M$. However we will not need this.

11.2. Localization of triangulated categories. The following result is well-known, although we did not find the precise statement we require. Since the proof is short we include it for the convenience of the reader.

Proposition 11.6. Let $T$ be a triangulated category admitting arbitrary coproducts and let $T \subset \text{Ob}(T)$ be a compact generator for $T$. Let $S \subset T(T, T)$ be a graded right Ore set and let $T_S$ be the full subcategory of $T$ spanned by the objects $X$ such that $T(s, X)$ is an isomorphism for all $s \in S$, or equivalently the objects for which

$$T(T, X) \rightarrow T(T, X)_S$$

is an isomorphism. Then $T_S$ is a triangulated subcategory of $T$ and moreover the inclusion functor $T_S \rightarrow T$ has a left adjoint, denoted by $(-)_S$ such that for $Y \in \text{Ob}(T)$ the induced map

$$(-)_S : T(T, Y) \rightarrow T_S(T_S, Y)_S$$
factors uniquely through an isomorphism
\[(11.2) \quad \mathcal{T}(T, Y)_S \cong \mathcal{T}_S(T_S, Y_S).\]

**Proof.** The fact that \(T_S\) is triangulated follows trivially from the 5-lemma. Let us now discuss the existence of the adjoint. Let \(C\) be the full subcategory of \(\mathcal{T}\) spanned by objects \(X\) such that all morphisms \(T \to X\) (not necessarily of degree zero) are annihilated after composing with some \(s : T \to T \in S\), or equivalently
\[(11.3) \quad \mathcal{T}(T, X)_S = 0\]
It is clear that \(C\) is triangulated and closed under arbitrary coproducts (the latter by the compactness of \(T\)).

For \(s \in S\) let \(C(s)\) be the cone of the morphism \(s : T \to \Sigma^{[n]} T\). It is clear that \(T_S = \langle C(s)_{s \in S} \rangle \). By the Ore condition on \(S\) the objects \(C(s)\) are in \(C\). Moreover as \(\langle C(s)_{s \in S} \rangle \) is an \(S\)-complex of \(C\) that the inclusion functor \(S\) is non-enhanceble functor.

Hence in particular \(C\) is compactly generated and using the Brown representability theorem we obtain that the inclusion functor \(C \to \mathcal{T}\) has a right adjoint \(U : \mathcal{T} \to C\) such that every \(X \in \mathcal{T}\) fits in a unique distinguished triangle
\[(11.4) \quad U X \to X \to VX \to \]
where \(V X \in C^\perp = T_S\). It follows easily that \(X \to VX\) is a functor \(\mathcal{T} \to C^\perp = T_S\). Applying \(\mathcal{T}(\cdot, Z)\) for \(Z \in T_S\) to (11.4) we obtain that \(V\) is the sought left adjoint \((-)_S\) to the inclusion \(T_S \to \mathcal{T}\).

Finally we discuss the formula (11.2). As \(\text{cone}(Y \to Y_S) = \Sigma U Y \in C\) we have \(\mathcal{T}(T, \text{cone}(Y \to Y_S))_S = 0\) by (11.3). Hence \((-)_S\) induces an isomorphism \(\mathcal{T}(T, Y)_S \cong \mathcal{T}(T, Y_S)_S \cong \mathcal{T}(T, Y_S) = T_S(T_S, Y_S)\) where the last equality is (11.2).

11.3. **A non-enhanceble functor.** Now let \(k\) be either a field of characteristic zero or an infinite field of characteristic \(\geq 3\). Put \(R = k[x_1, \ldots, x_n]\) and let \(K\) be the quotient field of \(R\). Furthermore let \(R[\epsilon]\) be the \(R\)-linear DG-algebra with \(|\epsilon| = -n + 2\), \(\epsilon^2 = 0\), \(d\epsilon = 0\). Let \(C(R, R)\) be the Hochschild complex of \(R\) and let \(HH^n(R, R) = H^n(C(R, R))\). Let \(T^n_{R/k} = \wedge^n_{R} \text{Der}_R(R, R)\). The HKR theorem gives an inclusion \(T^n_{R/k} \subset Z^n C(R, R)\) which induces an isomorphism \(T^n_{R/k} \cong H^n(K, K)\). For \(\eta \in T^n_{R/k}\) we let \(R_\eta\) be the \(k[\epsilon]\)-linear \(A_\infty\)-deformation of \(R[\epsilon]\) whose only higher multiplication is given by \(e\eta\).

As above, for an \(A_\infty\)-algebra \(A\) let \(C_\infty^*(A)\) be the DG-category of strictly unital right \(A_\infty\)-modules over \(A\) [7]. We put \(D(A) = H^\wedge(C_\infty^*(A))\). This is one of the many realizations for the derived category of an \(A_\infty\)-algebra (see [7, Théorème 4.1.3.1(D2)]) for which we consider \(C_\infty^*(A)\) to be its standard enhancement.

**Remark 11.7.** \(A\) is an \(A\)-\(A\)-bimodule and hence the left \(A\)-action on \(A\) defines \(A_\infty\)- quasi-isomorphism (see [7, Lemma 5.3.0.1]) \(A \to C_\infty^*(A)(A, A)\) which is however not an isomorphism.

**Proposition 11.8.** Assume \(T\) is a triangulated category with arbitrary coproducts and \(T\) is compact generator of \(T\) such that \(\tau (T, T) = R[\epsilon]\). Assume \(a\) is some \(A_\infty\)-enhancement of \(T\). Then there an \(A_\infty\)-quasi-equivalence \(a \cong C_\infty^*(R_\eta)\) for a suitable \(\eta \in T^n_{R/k}\) which sends \(T\) to an object isomorphic to \(R_\eta\) in \(H^\wedge(C_\infty^*(R_\eta)) = D(R_\eta)\) such that the induced map \(R[\epsilon] = \tau (T, T) \cong D(R_\eta)(R_\eta, R_\eta) = R[\epsilon]\) is the identity. Moreover \(\eta\) is uniquely determined by the triangulated structure on \(T\) and in particular is independent of the chosen quasi-equivalence.

**Proof.** Let \(R = a(T, T)\). By the work of Porta [11] the \(A_\infty\)-functor
\[Y : a \to C_\infty^*(R) : X \mapsto a(T, X)\]
is a quasi-equivalence which sends $T$ to $R$. Indeed $C^\infty_\omega(R)$ is pre-triangulated and so is a by the definition of enhancement. So $H^*(Y)$ is exact. Since the essential image of $H^*(Y)$ contains a generator of $H^*(C^\infty_\omega(R))$ (namely $R$) it is sufficient to show that $L := H^*(Y)$ is fully faithful. By the Brown representability theorem $L$ has a right adjoint $R$ which moreover commutes with coproducts (this follows from the fact that $L$ send the compact generator $T$ to the compact object $R$). Hence the full subcategory of $H^*(a)$ spanned by objects $X$ such that $X \to RLX$ is an isomorphism is closed under shifts, cones, summands and arbitrary coproducts. Moreover, applying $H^*(a)(T, −)$ we see that it contains $T$. Hence it must be $H^*(a)$ itself. From this one deduces that $L$ is fully faithful.

Now $R$ is a DG-algebra with cohomology $R[e]$ so it is $A_\infty$-isomorphic to a minimal $A_\infty$-structure on $R[e]$ with $m_2$ being the usual multiplication. For degree reasons, the only such $A_\infty$-structures are (up to $A_\infty$-isomorphism) of the form $R_q$. Hence after choosing an $A_\infty$-quasi-isomorphism $R_\eta \to R$ we obtain a quasi-equivalence $C^\infty_\omega(R) \to C^\infty_\omega(R_\eta)$ which sends $R$ to an object quasi-isomorphic to $R_\eta$ in a way which induces the identity on cohomology. Composing with $Y$ completes the proof of the first part of the proposition.

For $\lambda \in k^n$ let $K^*_\lambda$ be the $R$-Koszul complex on $(x_1 − \lambda_1, \ldots, x_n − \lambda_n)$. This is a resolution of $R_\lambda := R/((x_i − \lambda_i))_i$. Put $K^*_{\lambda,T} = K^*_\lambda \otimes_R T$. This is a complex in $\mathcal{T}$. The conditions (10.11) and (10.12) hold for $K^*_{\lambda,T}$ and hence the higher Toda bracket $(K^*_{\lambda,T})$ is a coset of $\sum \mathcal{T}(T, T)_{-n+2}(x_i − \lambda_i)$ in $\mathcal{T}(T, T)_{n+2} = R_T$. We define $\eta_{\lambda,T} \in R_\lambda$ such that $\eta_{\lambda,T} e$ is the sole element of the image of $(K^*_{\lambda,T})$ in $R_\lambda$.

By the constructed quasi-equivalence we have $\eta_{\lambda,T} = \eta_{\lambda,R_\eta}$. Alas we cannot immediately apply Theorem 10.8 to the right-hand side of this equality as the $A_\infty$-category spanned by the terms of the complex $K^*_{\lambda,R_\eta}$ (finite direct sums of $R_\eta$) is not minimal (see Remark 11.7). To work around this let $S := C^\infty_\omega(R_\eta)(R_\eta, R_\eta)$, which we regard as a one object $A_\infty$-category $(S, \ast)$. As in Remark 11.7 we obtain an $A_\infty$-quasi-isomorphism $R_\eta \to S$. Composing with $(S, \ast) \to C^\infty_\omega(R_\eta) : \ast \mapsto R_\eta$ we obtain a quasi-fully faithful $A_\infty$-functor $(R_\eta, \ast) \to C^\infty_\omega(R_\eta) : \ast \mapsto R_\eta$ which gives rise to a quasi-fully faithful $A_\infty$-functor

$$\mathcal{T}w R_\eta \to \mathcal{T}w C^\infty_\omega(R_\eta) \cong C^\infty_\omega(R_\eta)$$

which sends $K^*_{\lambda,R_\eta} \in \mathcal{T}w R_\eta$ to $K^*_{\lambda,R_\eta} \in C^\infty_\omega(R_\eta)$. It follows that we may perform the calculation of $\eta_{\lambda,R_\eta}$ in $\mathcal{T}w R_\eta$. As the $A_\infty$-subcategory of $\mathcal{T}w R_\eta$ spanned by direct sums of $R_\eta$ is minimal, we are now in a position to apply Theorem 10.8 and we obtain that, up to a global sign, $\eta_{\lambda,R_\eta}$ is the image of $\sum_{\sigma \in S_n} (-1)^{\sigma} \eta(x_{\sigma(1)} − \lambda_{\sigma(1)}, \ldots, x_{\sigma(n)} − \lambda_{\sigma(n)})$ in $R_\lambda$. Since $T^n_{R/k} = R \bigwedge_1 \partial/\partial x_1$, this is the same as the image of $n!\eta(x_1, \ldots, x_n)$. We obtain by varying $\lambda$ that $\eta$ is uniquely determined.

**Theorem 11.9.** Choose $0 \neq \eta \in T^n_{R/k}$ and put $a = C^\infty_\omega(K)$, $b = C^\infty_\omega(R_\eta)$. After extending $\eta$ to $T^n_{K/k} = T^n_{R/k} \otimes_R K$, we consider $K_\eta$ as an object in $b$. There is an $A_{n-1}$-functor

$$F : a \to b$$

which sends $K$ to $K_\eta$. The corresponding functor

$$H^*(F) : D(K) \to D(R_\eta)$$

does not lift to an $A_n$-functor, even after changing the enhancements on $D(K)$ and $D(R_\eta)$.

Before giving the proof of this theorem we show that it implies Theorem 1.1 in the introduction.

**Proof of Theorem 1.1.** From Theorem 11.9 we obtain that the hypotheses of Proposition 11.1 are satisfied for $(a, b, F)$ (with $n$ replaced by $n − 1$) and thus for $n \geq 14$ we obtain a triangulated category $D = \ldots$
\(H^n(\alpha \prod_{\rho \in \mathbb{B}} b)\) without \(A_\infty\)-enhancement with a semi-orthogonal decomposition
\[
D = \langle D(K), D(R_\eta) \rangle.
\]

**Proof of Theorem 11.9.** We first discuss the construction of the functor \(F\). To be compatible with Propositions 11.6 and 11.8, put \(T = D(R_\eta) = H^n(C_\infty^\nu(R_\eta))\) and let \(T\) be the object \(R_\eta\). Put \(S = R - \{0\}\). It is easy to that \(T_S = K_\eta\). Indeed \(K_\eta\) is in \(T_S\) and cone\(\eta \rightarrow K_\eta\) is in \(C\) by (11.3). In particular it follows by (11.2) that \(T(K_\eta, K_\eta) = K[\epsilon]\).

Choosing homotopies we obtain an \(A_2\)-functor
\[
F : K \rightarrow C_\infty^\nu(R_\eta) : K \mapsto K_\eta
\]
and the obstructions against extending \(\mu\) to an \(A_1\)-functor are in \(HH^j(K, T(K_\eta, K_\eta) - j + 2)\) for \(3 \leq j \leq i\) (see e.g. [12, Lemma 7.2.1]). Since \(T(K_\eta, K_\eta) = K[\epsilon]\) the obstructions vanish for \(j < n\). So \(F\) extends to an \(A_{n-1}\)-functor. Let \(\text{Free}^\nu(\cdot)\) be defined as \(\text{Free}(\cdot)\) but allowing arbitrary formal direct sums. If \(a\) is an \(A_0\)-category then so is \(\text{Free}^\nu(a)\) and similar statement is true for functors. We then obtain an \(A_{n-1}\)-functor \(\text{Free}^\nu(F) : \text{Free}(K) \rightarrow \text{Free}^\nu(C_\infty^\nu(R_\eta))\). Since \(\text{Free}(K)\) is quasi-equivalent to \(C_\infty^\nu(K)\) (both are models for \(D(K)\) which is semi-simple) and the direct sum defines an \(A_\infty\)-functor \(\text{Free}(C_\infty^\nu(R_\eta)) \rightarrow C_\infty^\nu(R_\eta)\), after choosing a suitable \(A_\infty\)-quasi-inverse to the first functor we obtain the sought \(A_{n-1}\)-functor \(\mu : C_\infty^\nu(K) \rightarrow C_\infty^\nu(R_\eta)\) which sends \(K\) to \(K_\eta\).

We claim that \(F\) does not lift to an \(A_n\)-functor, even if we change enhancements. If it did, the \(A_2\)-functor (11.5) would also lift to an \(A_2\)-functor, as by Proposition 11.8 the enhancement on \(C_\infty^\nu(R_\eta)\) is (weakly) unique and (as we have shown in the first paragraph) the object \(K_\eta\) is determined by the triangulated structure. If this were possible then it would induce the structure of an \(A_n\)-functor on the corestriction
\[
K \xrightarrow{\mu} \epsilon \subset C_\infty^\nu(R_\eta)
\]
where \(\epsilon\) is the full subcategory of \(C_\infty^\nu(R_\eta)\) spanned by the single object \(K_\eta\). Put \(K = C_\infty^\nu(R_\eta)(K_\eta, K_\eta)\). Since \(K_\eta\) is an \(K_\eta^{-1}R_\eta\)-bimodule, the left \(K_\eta^{-1}\)-action on \(K_\eta\) induces an \(A_\infty\)-quasi-isomorphism \(K_\eta \mapsto K = \epsilon\). Taking an \(A_\infty\)-quasi-inverse and composing with \(K \xrightarrow{\mu} \epsilon\) we obtain an \(A_n\)-morphism \(K \rightarrow K_\eta\) such that \(H^n(K) \rightarrow H^n(K_\eta) = K[\epsilon]\) is the natural inclusion. Such an \(A_n\)-morphism does not exist as \(\eta \neq 0\) [7, Chapitre B].
